Wax has been variously adulterated. *White lead* sinks to the bottom of the vessel when the wax is melted. *Starch*, *meal*, and other *insoluble substances* remain behind when the wax is dissolved in oil of turpentine or benzin; and the starch is known by producing a blue color with iodine added to water in which the wax has been boiled. *Water*, which is said to be sometimes fraudulently incorporated with it, by agitation when partially melted, is driven off by heat. *Fatty substances* render lime water turbid when agitated with it and allowed to stand. For the detection of stearin and stearic acid, M. Lebel dissolves the suspected wax in two parts of oil, beats the cerate thus formed with its weight of pure water, and then adds a few drops of solution of lead subacetate. If stearin be present, there will be an immediate decomposition, and the mixture will acquire an extraordinary solidity from the formation of lead stearate. (*Journ. de Pharm.*, 3e sér., xv.) Vogel proposes chloroform as a means of detecting the adulteration with fatty matters. That liquid dissolves only 25 per cent. of wax, but stearin and stearic acid completely. If, therefore, wax treated with 6 or 8 parts of chloroform loses more than one-quarter of its weight, it may be considered as impure. (*Ibid.*, xvii.) Overbeck detects stearic acid by the abundant effervescence produced from the escape of carbonic acid when a small portion of the suspected wax is boiled in a solution composed of one part of sodium carbonate and fifty of distilled water. (*P. J. Tr.*, xi. 128.) Fehling detects *stearic acid* and *resin* by boiling one part of the wax in twenty of alcohol, filtering the solution when cold, and then adding water. If either of these substances be present there will be a flocculent precipitate, whereas if the wax be pure there will scarcely be an observable turbidness. The natural fats, as *tallow*, *suet*, *lard*, etc., are not amenable to this test; but it may be applied by first saponifying them, and thus converting them into the fatty acids, as the stearic. But, as wax itself is somewhat liable to be affected, it is necessary to avoid too strong an alkaline solution, and too long boiling in the process. To obviate such a result, 30 grains of the wax are to be boiled with two or three fluidounces of water containing 6 grains of pure sodium hydrate, and the mass saturated with a very dilute acid, and heated. The wax is then to be separated, dried between folds of blotting-paper, and treated as above for stearic acid. (*Neues Repert. für Pharm.*, viii. 78.) For the detection of rosin, cold alcohol is sufficient. It dissolves the rosin, and yields it on evaporation, attended with a very small portion of pure wax, which yields 2·4 per cent. to cold alcohol. (Ed. Davies, *A. J. P.*, 1870, p. 537.) F. Jean states that a few drops of sulphuric acid added to the melted wax adulterated with rosin, cause a red color, or, if only 1 per cent. be present, a greenish tint. (*A. J. P.*, 1881, p. 307.) To detect *paraffin*, which is another adulteration said to be frequent, Prof. Landolt, of Bonn, heats the wax with fuming sulphuric acid (Nordhausen), which destroys the wax, converting it into a black jelly-like mass, while the paraffin is left as a transparent layer on the surface. (See *A. J. P.*, xxxiv. 35.) M. Lies Bodart detects the same impurity by a somewhat complex process, based on the etherification of the wax; the paraffin being left sufficiently pure to enable its proportion to be estimated. For the particulars of the process, the reader is referred to the *Journ. de Pharm. et de Chim.* (4e sér., iii. 287, 1866). A simpler method is that of M. Dullo, who treats the adulterated wax with ether. If this dissolves more than 50 per cent., the presence of paraffin is indicated. M. Payen resorts to the point of fusion as a means of detecting paraffin. This substance melts

at a lower temperature than wax, and lowers the melting point of wax with which it is mixed. (*Ibid.*, 4e sér., ii. 233.) White wax should not melt below 65° C. (149° F.); yellow not below 62·5° C. (144·5° F.). (*Br.*) *Japan wax* is said also to be largely employed for adulterating beeswax; so that sometimes but little of the product of the bee is to be found in the mixture. To detect Japan wax, M. Dullo boils together for a minute 10 Gm. (150 grains) of wax, 120 Gm. of water, and 1 of soda. If there be Japan wax present, a soap will immediately form, which will slowly solidify on cooling. Beeswax does not saponify under these circumstances. (*Ibid.*, 4e sér., i. 448.) Ceresin, a principle obtained from ozokerite (see PART II.), is also employed as an adulterant, and is manufactured largely for that purpose in Vienna. It is only native paraffin, and of course answers to the tests for that substance. There are other less precise methods of detecting adulterations. Thus, spermaceti and lard render wax softer and less cohesive, of a smoother and less granular fracture, and of a different odor when heated. The melting point and specific gravity are lowered by tallow, suet, and lard. *Legrip's cereometer* is based upon the altered specific gravity of wax when adulterated. Any one may apply this principle by making such a mixture of alcohol and water that pure wax will neither sink nor rise in it, but remain wherever placed. (See page 351.) Adulterated wax would either float or sink in this liquid. Pereira says that pure wax is yellowish white; and that the white wax in circular cakes always contains spermaceti, added to improve its color. The most valuable information, however, is obtained by the determination, according to Hübl's process, of the three chemical constants,—viz., acid value, 20; ester value, 75; and saponification value, 95. In yellow wax the iodine value, 7·9 to 8·9, is also of use; in white wax the bleaching process has altered the bodies which absorb the iodine. (See also *Chem. Zeit.*, 1893, 918; *Proc. A. P. A.*, 1894, 957; *Drug. Circ.*, 1898, 33; *Amer. Drug.*, 1898, 97.)

Medical Properties and Uses. Wax has little effect upon the system. Under the impression that it sheathed the inflamed mucous membrane of the bowels, it was formerly prescribed in *diarrhœa* and *dysentery;* and it is mentioned by Dioscorides as a remedy in the latter complaint; but at the present time, we suppose, no one would think of employing wax for such purposes. Its sole use in modern medicine is in the formation of ointments, cerates, plasters, and suppositories, surgical dressings, etc., in which it acts mechanically, either giving stiffness or serving to protect from water. It is an ingredient in almost all the official cerates, which owe to it their general title.

3. VEGETABLE WAX. Many vegetable products contain wax. It exists in the pollen of numerous plants, and forms the bloom or glaucous powder which covers certain fruits, and the coating of varnish with which leaves are sometimes supplied. In some plants it is so abundant as to be profitably extracted for use. Such is the *Ceroxylon andicola*, a lofty palm growing in the South American Andes. Upon the trunk of this tree, in the rings left by the fall of the leaves, is a coating of wax-like matter, about one-sixth of an inch thick, which is removed by the natives and employed in the manufacture of tapers. It contains, according to Vauquelin, two-thirds of a resinous substance and one-third of pure wax. Two kinds of wax are collected in Brazil, one called *carnauba*,* from the leaves of the *Copernicus cerifera*, a palm, which forms large forests in the province of Ceara, the other *ocuba*, from the fruit of a shrub of the

* *Carnauba Wax* is collected by cutting out the leaf-buds, drying and beating them, and melting the powder thus detached in water. According to Nevil Story Maskelyne, it consists chiefly of melissyl-alcohol, $C_{30}H_{62}O$, which saponifies, another alcohol, $C_{23}H_{48}O$, and small quantities of resin and a substance melting at 150° C. (221° F.). Berard believes it to be composed of free cerotic acid and melissyl ether. H. Stürke has stated as the result of an investigation that carnauba wax contains: a hydrocarbon, melting at 59° C.; an alcohol, $C_{23}H_{56}.CH_2OH$, melting at 76° C.; myricyl alcohol, $C_{30}H_{61}.OH$, melting at 85·5° C.; a diatomic alcohol, $C_{25}H_{50}.(OH)_2$, melting at 103·5°–103·8° C.; an acid, $C_{24}H_{48}O_2$, isomeric with lignocerotic acid, melting at 72·5° C.; an acid, $C_{27}H_{54}O_2$, isomeric with cerotic acid, melting at 79° C.; and an acid, or rather the lactone (anhydride) of an acid, $C_{19}H_{38}\begin{cases}CH_2OH\\COOH\end{cases}$, melting at 103·5° C., from which an acid, $C_{19}H_{38}(COOH)_2$, melting at 90° C. has been prepared. (Schaedler, *Technol. der Fette und Oele*, 2te Auf., p. 884.) It is hard, brittle, and buff-colored, yellow, or greenish, resembling the resins more than wax, and melts at 85° C. (185° F.), which is much higher than the fusing point of other kinds of vegetable wax. "It takes a fine polish when rubbed with any soft material," does not receive impressions from the finger at the natural temperature of the hand, and is adapted for polishing furniture, either alone or mixed with wax. 2,000,000 pounds of it are said to be annually produced in Brazil, where it is largely used, mixed with tallow, in making candles, etc.

Under the name of *Ocotilla wax*, Mrs. Helen Abbott Michael described (*A. J. P.*, Feb. 1885) a wax which she has obtained from the bark of the *Fouquieria splendens*, and believes to be a new variety. A wax which is said to be used, under the name of *Arbol de la Cera*, in Mexico not only for domestic purposes, but also as a remedy in diarrhœa and jaundice, is that obtained by boiling the fruit of the *Myrica jalapensis* in water. It is greenish or yellow, more brittle and unctuous than beeswax, has a feeble odor, a slightly bitter taste, and a density nearly equal to that of water, and melts at 43°; but on exposure the fusing point rises to 47·5°. It is wholly soluble in boiling ether, insoluble in water, sparingly soluble in cold alcohol, and dissolves in twenty parts of boiling alcohol, depositing the greater part on cooling; alkalies saponify it readily. (*A. J. P.*, xv. 339, 1885.)

province of Para. (*Journ. de Pharm.*, 3e sér., v. 154.)* A form of vegetable wax sometimes seen in this country is that derived from *Myrica cerifera*, and commonly called *myrtle wax*. The *wax myrtle* is an aromatic shrub, from one to twelve feet high, growing in the United States, from New England to Louisiana, and flourishing especially on the sea-coast. The fruit, which grows in clusters closely attached to the stems and branches, is small, globular, and covered with a whitish coat of wax, which may be separated for use. Other parts of the plant are said to possess medical virtues. The bark of the root is acrid and astringent, and in large doses emetic, and has been popularly employed in jaundice. The process for collecting the wax is simple. The berries are boiled in water, and the wax, melting and floating on the surface, is either skimmed off and strained, or allowed to concrete as the liquor cools, and then removed. To render it pure, it is again melted and strained, and cast into large cakes. It is collected in New Jersey, North Carolina, and New England, and particularly in Rhode Island.

Myrtle wax is of a pale grayish-green color, somewhat diaphanous, more brittle and unctuous to the touch than beeswax, of a feeble odor, and a slightly bitterish taste. It is about as heavy as water, and melts, according to Dr. G. E. Moore, at from 46·6° C.–48·8° C. (116° F.–120° F.). It is insoluble in water, scarcely soluble in cold alcohol, soluble, excepting about 13 per cent., in twenty parts of boiling alcohol, which deposits the greater portion on cooling, soluble also in boiling ether, and slightly so in oil of turpentine. It is readily saponifiable with the alkalies. By Dr. John it was found to found to consist, like beeswax, of cerin and myricin, containing 87 per cent. of the former and 13 of the latter; but a more accurate analysis by Dr. Moore gives as its constituents one part of palmitin and four of palmitic acid, with a little laurin or lauric acid. (*Am. Journ. of Sci. and Arts*, 1852, p. 319.) The green color and bitterness depend upon distinct principles, which may be separated by boiling with ether. On cooling, the wax is deposited colorless, while the ether remains green. The color is ascribed by Dr. Moore to chlorophyll.

Medical Properties and Uses. This variety of wax has been popularly employed in the United States as a remedy for *dysentery;* in which disease Dr. Fahnestock gave the powdered wax in doses of a teaspoonful (3·75 C.c.) frequently repeated, with alleged great advantage. (*Am. Journ. of Med. Sci.*, ii. 313.) It is occasionally substituted by apothecaries for beeswax in the formation of plasters, and is used in the preparation of tapers and candles. It is somewhat fragrant when burning, but emits a less brilliant light than common lamp oil.

CERATA. Cerates.

(CĒ-RĀ′TA.)

Cérats, Céréotés, *Fr.;* **Cerate, Wachssalben,** *G.*

These are unctuous substances consisting of oil or lard, mixed with wax, spermaceti, or resin, to which various medicaments are frequently added. Their consistence, which is intermediate between that of ointments and that of plasters, is such that they may be spread at ordinary temperatures upon linen or leather, by means of a spatula, and do not melt or run when applied to the skin. In preparing them, care should always be taken to select the oil or lard perfectly free from rancidity. In reference to the wax, too, there would seem to be a choice, as experience has shown that cerates made with yellow wax keep longer unchanged than those made with white or bleached wax, probably because there is in yellow wax some principle which cor-

* *Japanese Wax.* A substance under this name has been imported into Europe in considerable quantities, either directly from Japan, or through the Chinese ports. It is obtained from the berries of the *Rhus succedaneum* of Linnæus, and in small amount from the *R. sylvestris* and *R. vernicifera*, or lacquer plant. The partially dried berries are crushed, winnowed, steamed, placed in hemp cloth bags, steamed again, and pressed in a wooden wedge press. They yield about 15 per cent. of a coarse greenish tallowy mass. It has come in two forms, the one, as originally distinguished by Mr. Hanbury, of circular cakes, about four inches in diameter, and an inch thick, flat on one side and somewhat convex on the other; the second, as brought directly from Japan, of large rectangular blocks, which are packed in chests. It bears a considerable resemblance to purified beeswax, but is not quite so white, having a slightly yellowish tint, is softer, more friable, and has a somewhat rancid smell and taste. Its melting point is below that of wax, varying from 49° C. (120° F.), as stated by Prof. Procter, to 52° C. (125° F.), and even 55° C. (131° F.), as observed in different specimens by Mr. Hanbury. Meyer noticed a sample melting at 42° C. (107° F.). It is much more soluble in alcohol than is beeswax, is saponifiable with the alkalies, and is in the main a glyceride of palmitic acid with smaller amounts of the glycerides of stearic and arachidic acids. It has been employed in the preparation of candles, which yield as brilliant light as those made of common wax. It has been found useful in the preparation of cerates, etc. From Roucher's experiments it appears that there are two melting points of this wax, one corresponding closely with Prof. Procter's results, while the same wax rapidly heated to a point above that of fusion and then allowed to cool, if plunged into water at 42° C., melts into a transparent liquid; consequently melting at a point 12° C. below its freezing point in its ordinary state, which was 54° C.; the two temperatures being about equivalent in Fahrenheit's scale to 107° and 129°. (*P. J. Tr.*, Aug. 1872.)

rects the tendency of fatty matters to become rancid. (F. Bringhurst, *A. J. P.*, 1869, 59.) The liquefaction should be effected by a very gentle heat, which may be applied by means of a water-bath; and during the refrigeration the mixture should be well stirred, and the portions which solidify on the sides of the vessel should be made to mix again with the liquid portion, until the whole assumes the proper consistence, or, as some prefer, the melted cerate is allowed to cool quickly without stirring. When a large quantity is prepared, the mortar or other vessel into which the mixture may be poured for cooling should be previously heated by means of boiling water. It has been proposed to substitute paraffin for wax in the preparation of the cerates, but the great tendency to produce granulation in the finished cerate has largely prevented its use. It is, we think, unfortunate that this class of preparations has been abandoned in the British Pharmacopœia; the several cerates having been rejected, or transferred to the class of Ointments. Independently of the connection between the name and one of the characteristic constituents of the cerates, there is a ground of difference between them and the ointments in their consistence; that of the cerates being such as to render them especially suitable for spreading on linen, while that of ointments is peculiarly adapted to inunction.*

CERATUM. U.S. Cerate.

(CḘ-RĀ'TŬM.)

Ceratum Adipis, *U. S.* 1860; Ceratum Simplex, *U. S.* 1850; Cérat simple, *Fr.;* Einfaches Cerat, Wachssalbe, *G.*

"White Wax, *three hundred grammes* [or 10 ounces av., 255 grains]; Lard, *seven hundred grammes* [or 24 ounces av., 303 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt them together, and stir the mixture constantly until it is cool." *U. S.*

In the preparation of this cerate, peculiar care should be taken that the oleaginous ingredient be entirely free from rancidity, and that the heat employed be not sufficient to produce the slightest decomposition; for the value of the preparation depends on its perfect blandness. To avoid change, it should be put up in small jars, and covered closely with tin-foil so as to exclude the air. It is used for dressing *blisters*, *wounds*, etc., in all cases in which the object is to prevent the contact of air and preserve the moisture of the part and at the same time to avoid all irritation. It is sometimes improperly employed as the vehicle of substances to be applied by inunction. For this purpose lard should be used in winter, and simple ointment in summer, the cerate having too firm a consistence. George W. Sloan recommends simple cerate as a pill excipient for certain oxidizable substances and special uses. (*Proc. A. P. A.*, 1884.)

CERATUM CAMPHORÆ. U.S. Camphor Cerate.

(CḘ-RĀ'TŬM CĂM'PHO-RÆ.)

"Camphor Liniment, *one hundred grammes* [or 3 ounces av., 230 grains]; White Wax, *three hundred grammes* [or 10 ounces av., 255 grains]; Lard, *six hundred grammes* [or 21 ounces av., 72 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the White Wax and Lard with the aid of a gentle heat; then add the Camphor Liniment, and stir the mixture occasionally, until it has become cold." *U. S.*

The proportion of camphor has been greatly increased in this preparation by the U. S. P. 1890; it now contains 2 per cent. of camphor, that of the U. S. P. 1880 contained only three-fifths of 1 per cent. This preparation was introduced in the U. S. P. 1880 primarily for use in making cerate of subacetate of lead by the extemporaneous process. It was subsequently found useful as a slightly stimulating dressing, hence the proportion of camphor has been increased.

CERATUM CANTHARIDIS. U.S. (Br.) Cantharides Cerate.

(CḘ-RĀ'TŬM CAN-THĂR'Ị-DĬS.)

Emplastrum Cantharidis, *Br.;* Cantharides Plaster; Emplastrum Cantharidum (Vesicatorium) Ordinarium, *P. G.;* Emplastrum Epispasticum, s. Vesicatorium, s. Vesicans; Emplâtre de Cantharides, Emplâtre vésicatoire, *Fr.;* Spanischfliegen Pflaster, Blasenpflaster, *G.*

"Cantharides, in No. 60 powder, *three hundred and twenty grammes* [or 11 ounces av., 126 grains]; Yellow Wax, *one hundred and eighty grammes* [or 6 ounces av., 152 grains]; Resin, *one hundred and eighty grammes* [or 6 ounces av., 152 grains]; Lard, *two hundred and twenty grammes* [or 7 ounces av., 332 grains]; Oil of Turpentine, *one hundred and fifty cubic centi-*

* Dr. W. H. Mielcke (*Pharm. Centralb.*, 1881, Nos. 20, 21) proposes a class of preparations, to which he has given the name "*Steatins*," "*Steatinum*." These are of about the consistence of cerates, of varied composition, and contain usually a considerable portion of tallow. The *Steatinum Iodoformi* offers a fair specimen of the class. "Take of mutton tallow 18 parts, expressed oil of nutmeg 2 parts, iodoform, in fine powder, 1 part. Melt the tallow and add the other ingredients." For other formulas, see *A. J. P.*, 1881, p. 404.

meters [or 5 fluidounces, 35 minims], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Moisten the Cantharides with the Oil of Turpentine, and set the mixture aside, well covered, for forty-eight hours. Then add it to the Yellow Wax, Resin, and Lard, previously melted and strained through muslin, and keep the mixture in a liquid condition, by means of a water-bath, stirring occasionally, until its weight has been reduced to *one thousand grammes* [or 35 ounces av., 120 grains]. Then remove it from the bath, and stir it occasionally until it is cool." *U. S.*

The British Pharmacopœia directs of Cantharides, in powder, 3½ *ounces* (Imperial) or thirty-five grammes; Yellow Beeswax, Lard, and Resin, each, 2 *ounces* (Imp.) or twenty grammes; and Soap Plaster, ½ *ounce* (Imp.) or five grammes; melts the Resin, Soap Plaster, Wax, and Lard together; then introduces the Cantharides, mixes the whole thoroughly, and continues to stir the mixture while cooling. (See *Emplastrum Cantharidis.*)

This is the common well-known *blistering plaster.* As it can be readily spread without the aid of heat, it is properly a cerate, and is, therefore, correctly named in the U. S. Pharmacopœia. The process now official differs from that of previous Pharmacopœias in the use of Oil of Turpentine; the previous maceration of the cantharides with this solvent has for its object the softening and extraction of the cantharidin; the present cerate is not so firm in consistence as that made by the U. S. P. 1880, for, although some of the oil of turpentine is evaporated by the heat employed, sufficient is still retained by the process to render the cerate softer. There can be no question of the advantage of retaining the cantharides in contact with hot liquefied fatty bodies to facilitate the extraction of the cantharidin. The cerate is essentially the same as prepared by the two processes; though the U. S. formula has a decided advantage over the British, in keeping the mixture of the flies and the other ingredients for some time at an elevated temperature, while in the latter they are allowed to cool after being mixed with the fatty matters. Care was formerly considered requisite, in making the cerate, not to injure the flies by heat. It was, therefore, recommended that they should not be added to the other ingredients until immediately before these begin to stiffen, after having been removed from the fire; and, though this direction has been omitted, no provision is made for the continued application of heat. From the experiments of Mr. Donovan (*Dublin Med. Press*, Aug. 1840), and those of Professor Procter (*A. J. P.*, xiii. 302, and xxiv. 296), it may be inferred that the vesicating principle of Spanish flies is not injured or dissipated by a heat under 148·8° C. (300° F.), and that an elevated temperature, instead of being hurtful, is positively advantageous in the preparation of the cerate. The cantharidin is thus more thoroughly dissolved by the oleaginous matter, and consequently brought more efficiently into contact with the skin, than when retained in the interior of the tissue of the fly. Another advantage, stated by Donovan, is that the moisture usually existing to a certain extent in all the ingredients of the cerate is thus dissipated, and the preparation is less apt to become mouldy, or otherwise to undergo decomposition. Instead, therefore, of waiting until the melted wax, resin, and lard begin to stiffen, it is better to add the powder before the vessel is removed from the fire. Mr. Donovan recommends that, as soon as the other ingredients are melted, the powdered flies should be added, and the mixture stirred until the heat is shown by a thermometer to have risen to 121·1° C. (250° F.), when the vessel is to be removed from the fire, and the mixture stirred constantly until cool. At the heat mentioned, ebullition takes place in consequence of the escape of the moisture contained in the materials. In the cerate thus prepared, the active matter has been dissolved by the lard, and the powder may be separated, if deemed advisable, by straining the mixture before it solidifies. Care should be taken that the temperature be not so high as to decompose the ingredients; and it would be better to keep it within 100° C. (212° F.), by means of a water-bath, as in the U. S. process, than to incur any risk from its excess. Violent irritation and even vesication of the face of the operator are stated to have resulted from exposure to the vapors of the liquid, at a temperature of 121·1° C. (250° F.). (*P. J. Tr.*, ii. 391.) From an experiment, however, of Professor Procter, it appears that, though cantharidin begins to volatilize slightly at 121·1° C. (250° F.), and rapidly rises in vapor and sublimes at from 205·5° C. to 211·1° C. (402° F. to 412° F.), yet it is not decomposed unless by increasing the heat considerably above the last-mentioned point. (*A. J. P.*, xxiv. 296 and 298.) Dieterich states that the activity is greatly increased by the use of acid in the manufacture. Thus, for every 250 Gm. of powdered flies used he adds to the melted mass 1 Gm. sulphuric acid and 10 Gm. alcohol (90 per cent.), keeps the mass for two hours at 70° C., and finally adds 2 Gm. barium carbonate rubbed up with 6 Gm. alcohol. (*Pharm. Cent.*, 1892, 425.) It is desirable that the flies should be very finely pulverized. Coarsely powdered cantharides should not be

used, because of the imperfect and unequal distribution of the vesicating agent. Powdered euphorbium is said to be sometimes fraudulently added.

The cerate will always raise a blister in ordinary conditions of the system, if the flies are good, and not injured in the preparation. It should be spread on soft leather, though linen or even paper will answer the purpose when that is not to be had. An elegant mode of preparing it for use is to spread a piece of leather, of a proper size, first with adhesive plaster, and afterwards with the cerate, leaving a margin of the former uncovered, in order that it may adhere to the skin. Heat is not requisite, and should not be employed in spreading the cerate. Some sprinkle powdered flies upon the surface of the plaster, press them lightly with a roller, and then shake off the portion which has not adhered; but, if the flies originally employed were good, this addition is superfluous. The habit of applying over the surface with a brush an ethereal tincture of cantharides, which leaves a thin coating of extract, renders the preparation more certain.

Upon the application of the plaster, the skin should be moistened with warm vinegar or other liquid. In adults, when the full action of the flies is desired, and the object is to produce a permanent effect, the application should be continued for eight hours, and on the scalp for twelve hours. In very delicate persons, however, or those subject to strangury, or upon parts of a loose texture, or when the object is merely to produce a blister to be healed as quickly as possible, the plaster should remain no longer than is necessary for the production of full redness of the skin, which generally occurs in five or six hours, or even in a shorter time. It should then be removed, and followed by a flaxseed poultice, or some other emollient dressing, under which the cuticle rises, and a full blister is usually produced. By this management the patient will generally escape strangury, and the blister will very quickly heal after the discharge of the serum.* In young children, cantharides sometimes produce alarming and even fatal ulceration, if too long applied, and from two to four hours are usually sufficient for any desirable purpose. When the head, or other very hairy part, is to be blistered, an interval of ten or twelve hours should, if possible, be allowed between the shaving of the part and the application of the plaster, so that the abrasions may heal, and some impediment be offered to the absorption of the flies. After the blister has been formed, it should be opened at the most depending parts, and, the cuticle being allowed to remain, should be dressed with simple cerate; but, if it be desirable to maintain the discharge for a short time, resin cerate should be used, and the cuticle removed if it can be done without inconvenience. When it is wished that the blistered surface should heal as soon as possible, Goulard's cerate should be freely applied. The effects of an issue may be obtained by employing savine ointment, or the ointment of Spanish flies, as a dressing. If much inflammation takes place in the blistered surface, it may be relieved by emollient poultices, weak lead water, or Goulard's cerate. When there is an obstinate indisposition to heal, we have found nothing so effectual as zinc ointment with two to four grains of carbolic acid to the ounce.

Various preparations of cantharides have been proposed and employed as substitutes for the cerate. They consist for the most part of cantharidin, more or less pure, either dissolved in olive oil and applied to the skin by means of a piece of paper saturated with it, or incorporated with wax and spread in a very thin layer upon fine waxed cloth, silk, or paper, constituting *blistering cloth*, *blistering paper*, *vesicating taffeta*, etc. The advantages of these preparations are that they occupy less space, are more portable, and, being very pliable, are more easily adapted to irregularities of the surface. Absolutely pure cantharidin is expensive and not requisite,† as extracts of cantharides, made with ether, alcohol, or boiling

* The late Dr. M. B. Smith, of Philadelphia, informed us that he had frequently employed uva ursi as a preventive of *strangury* from blisters, and had never found it to fail. He gave a small wineglassful of the decoction of uva ursi every hour, commencing two hours after the application of the blister. Camphor is sometimes incorporated with the blistering cerate to prevent strangury, though with doubtful effect. A plan proposed by M. Vée is to spread over the surface of the plaster, when ready for delivery, by means of the finger, a saturated solution of camphor in ether. The ether evaporates, leaving a thin coating of camphor uniformly diffused. (*Journ. de Pharm.*, 3e sér., viii. 68.) Guyot Dannecy believes camphor to be useless in this connection, and recommends dusting the blister with bicarbonate of sodium and powdered cantharides in equal parts. The late Dr. Joseph Hartshorne, of Philadelphia, was in the habit, in cases where he apprehended strangury, of directing four grains of opium and twenty of camphor to be mixed with the cerate of a blister of large size, and experienced the happiest effects from the addition.

† Dragendorff (*A. J. P.*, 1872, p. 273) recommends *sodium cantharidate*. M. E. Delpech (*A. J. P.*, xlii. 240) proposes the use of *potassium cantharidate* in substance or solution. He prepares it by dissolving two parts of cantharides in 150 parts of alcohol, and adding 1·6 parts of caustic potash dissolved in a very little water. The whole becomes a crystalline mass, from which the alcohol may be separated by pressure. See also R. Rother, *Chicago Pharmacist*, Nov. 1872.

water, will answer every purpose. Henry and Guibourt give the following formula. Digest powdered cantharides in ether, distil off the ether, evaporate the residue by means of a salt-water bath, until ebullition ceases, melt the mass which remains with twice its weight of wax, and spread the mixture upon waxed cloth. The *waxed cloth* may be prepared by spreading upon linen or muslin a mixture composed of 8 parts of white wax, 4 of olive oil, and 1 of turpentine, melted together. An extract of cantharides of a buttery consistence, said to act very efficiently when applied by means of paper greased with it, is prepared by digesting 4 parts of flies with one part of strong acetic acid and 16 of alcohol, straining, filtering, and evaporating at a moderate heat.* A preparation which received the favorable report of a committee of the Society of Pharmacy, at Paris, is the following, proposed by M. Dubuisson. Four parts of a hydro-alcoholic extract of the flies, made by maceration, are mixed with an aqueous solution of one part of pure gelatin, so as to obtain a solution of suitable consistence, which is then applied upon a piece of extended waxed cloth, care being taken that the brush should always have the same direction. When the first layer has dried, a second and a third are to be applied in the same manner. The gelatin renders the cloth more adhesive and less deliquescent. The hydro-alcoholic extract is preferred to the alcoholic, because it contains less of the green oil, which does not readily mix with the other ingredients. The committee, however, preferred the aqueous extract, as cheaper and more active. This taffeta has been tried, and found to raise blisters in four hours. (*Journ. de Pharm.*, 3e sér., viii. 67.) For very speedy vesication, an infusion of the flies in strong acetic acid is sometimes employed. None of these preparations are likely to supersede the cerate, but the demand for them has been met by introducing into the Pharmacopœia *Charta Cantharidis* U. S. P. 1880 and *Collodium Cantharidatum*.

CERATUM CETACEI. U. S. Spermaceti Cerate.

(CĒ-RĀ'TŬM CĒ-TĀ'CĒ-Ī.)

Emplastrum Spermatis Ceti, Ceratum Labiale Album; Cérat de Blanc de Baleine, Onguent blanc, *Fr.;* Wallrath-Cerat, *G.*

"Spermaceti, *one hundred grammes* [or 3 ounces av., 230 grains]; White Wax, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Olive Oil, *five hundred and fifty grammes* [or 19 ounces av., 175 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt together the Spermaceti and White Wax; then add the Olive Oil previously heated, and stir the mixture constantly until it is cool." *U. S.*

The direction to heat the oil before adding it to the other ingredients is important. If added cold, it is apt to produce an irregular congelation of the wax and spermaceti, and thus to render the preparation lumpy. The cerate is employed as a dressing for blisters, excoriated surfaces, and wounds, and as the basis of more active preparations. When the ingredients are pure and sweet, it is perfectly free from irritating properties. The present formula contains a little less spermaceti than that of the U. S. P. 1870. From experiments made by Mr. J. B. Barnes, it appears that this cerate keeps much better when made of unbleached materials than when prepared with olive oil and wax previously bleached. (*P. J. Tr.*, 1861, p. 352.)

CERATUM PLUMBI SUBACETATIS. U. S. (Br.) Cerate of Lead Subacetate. [Goulard's Cerate.]

(CĒ-RĀ'TŬM PLŬM'BĪ SŬB-ĂÇ-Ē-TĀ'TĪS.)

Unguentum Glycerini Plumbi Subacetatis, *Br.;* Unguentum Plumbi Subacetatis Compositum; Compound Ointment of Subacetate of Lead; Unguentum Plumbi, *P. G.;* Ceratum cum Subacetate Plumbico; Cérat de Saturne, Saturné de Goulard, *Fr.;* Bleisalbe, Bleicerat, *G.*

"Solution of Lead Subacetate, *two hundred grammes* [or 7 ounces av., 24 grains]; Camphor Cerate, *eight hundred grammes* [or 28 ounces av., 96 grains], To make *one thousand grammes*

* *Ceratum Extracti Cantharidis.* The U. S. Pharmacopœia formerly recognized the Cerate of the Extract of Cantharides, and gave for it the following formula: "Cantharides, in No. 60 powder, *thirty parts* [or six ounces av.]; Resin, *fifteen parts* [or three ounces av.]; Yellow Wax, *thirty-five parts* [or seven ounces av.]; Lard, *thirty-five parts* [or seven ounces av.]; Alcohol, *a sufficient quantity.* Moisten the Cantharides with *eighteen parts* [or four fluidounces] of Alcohol, and pack firmly in a cylindrical percolator; then gradually pour on Alcohol, until *one hundred and eighty parts* [or two and a half pints] of percolate are obtained, or until the Cantharides are exhausted. Distil off the Alcohol by means of a water-bath, transfer the residue to a tared capsule and evaporate it, on a water-bath, until it weighs *fifteen parts* [or three ounces av.]. Add to this the Resin, Wax, and Lard, previously melted together, and keep the whole at a temperature of 100° C. (212° F.) for fifteen minutes. Lastly, strain the mixture through muslin, and stir it constantly until cool." *U. S.* This preparation was introduced in 1860 as a substitute for the older cerate, but has failed to sustain its alleged superiority, and has very properly been dismissed.

[or 35 ounces av., 120 grains]. Mix them thoroughly. This Cerate should be freshly prepared, when wanted." *U. S.**

The British Pharmacopœia makes an ointment by mixing glycerin of subacetate of lead with soft and hard paraffin together. (See *Unguentum Glycerini Plumbi Subacetatis;* also *Glycerini Plumbi Subacetatis.*)

This cerate received the name by which it is commonly known from M. Goulard, by whom it was employed and recommended. It immediately begins to assume a yellowish color, and after a short time becomes so rancid as to be scarcely fit for use. Hence it should be prepared in small quantities at a time. The addition of a few drops of acetic acid prevents the yellow color from appearing, and there seems to be no objection to its use. The late Mr. Jacob Bell found it more satisfactory when made with yellow wax. (*P. J. Tr.*, 1859, p. 459.) Eggenfels, a German pharmacist, recommends the following method of proceeding to prevent its change of color. The wax and oil are melted in a water-bath; the solution of lead subacetate, previously heated, is added in small portions successively, and the mixture well stirred, and digested for some time; a partial saponification takes place, and an emulsion afterwards; and the cerate retains its white color. (See *A. J. P.*, 1861, p. 408.) It is used chiefly in *excoriations*, *burns*, *scalds*, and *chilblains*, and in *cutaneous eruptions.* Wherever there is an acute active inflammation of the skin it is a most efficient remedy.

CERATUM RESINÆ. U. S. (Br.) Resin Cerate. [Basilicon Ointment.]

(CḘ-RĀ-TŬM RḘ-ṢĪ'NÆ.)

Unguentum Resinæ, *Br.;* Ointment of Resin, Unguentum Basilicum; Cérat de Résine anglais, *Fr.;* Harzcerat, *G.*

"Resin, *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Yellow Wax, *one hundred and fifty grammes* [or 5 ounces av., 127 grains]; Lard, *five hundred grammes* [or 17 ounces av., 278 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt them together at a moderate heat, strain the mixture through muslin, and allow it to cool without stirring. In cold weather use the following proportions: Resin *three hundred and fifty grammes* [or 12 ounces av., 151 grains]; Yellow Wax, *one hundred and twenty grammes* [or 4 ounces av., 101 grains]; Lard, *five hundred and thirty grammes* [or 18 ounces av., 305 grains]." *U. S.*

"Take of Resin, Yellow Beeswax, and Olive Oil, each, 8 *ounces* (Imperial) or 200 grammes; Lard, 6 *ounces* (Imp.) or 150 grammes. Add the Lard and Olive Oil to the previously melted Resin and Beeswax; strain; stir until cold." *Br.*

The U. S. preparation does not differ greatly from that formerly official. An improvement has been made in the manipulation over that for the ointment official in 1870, in directing the ointment not to be stirred, a better consistence being secured by this change. The straining is directed in consequence of the impurities which resin often contains. A novelty has been introduced in an official process by the addition of a "cold weather" formula. This seems to be of doubtful utility, individual susceptibility to the perception of heat and cold varying greatly: if an alternative formula were really desirable, "cold weather" should be defined by a certain number of degrees of temperature, but the inquiry will naturally arise, if a "cold weather" process is desirable in the Pharmacopœia for any cerate, why was it not appended for each official cerate? The British process (1898) discards the simple ointment and almond oil previously used (1885), and substitutes lard and olive oil. It is difficult to explain the advantage of the use of any fixed oil whatever in this preparation, for if it be desirable to soften the consistence, the quantity of resin or wax can easily be diminished. Resin cerate, commonly called *basilicon ointment*, is much used as a gently stimulant application to *blistered surfaces*, *indolent ulcers*, *burns*, *scalds*, and *chilblains.* We have found no application more effectual in disposing the *ulcers* which follow *burns* to heal.

CERII OXALAS. U. S., Br. Cerium Oxalate. [Cerous Oxalate.]

$Ce_2(C_2O_4)_3 . 9H_2O$; 704·78. (CḘ'RĮ-Ī ŎX'Ą-LĂS.) $Ce_2(C_2O_4)_3 + 9H_2O$; 708.

"Cerium Oxalate, $Ce_2(C_2O_4)_3,9H_2O$, may be obtained by interaction of a soluble cerium salt and a soluble oxalate. It usually contains some lanthanum oxalate and didymium oxalate." *Br.*

Oxalate of Cerium; Cerium Oxalicum, Oxalas Ciricus; Oxalate de Cérium, *Fr.;* Oxalsaures Ceroxydul, Cerium Oxalat, *G.*

* The British Pharmacopœia of 1867 takes *six fluidounces* of the Solution of Subacetate of Lead, *eight ounces* [avoirdupois] of White Wax, *a pint* [Imperial measure] of Oil of Almonds, and *sixty grains* of Camphor. The wax and four-fifths of the oil are melted by means of a water-bath, and the solution of subacetate of lead added gradually, stirring as the mixture cools; the camphor, dissolved in the remaining fifth of the oil, is then added, and the whole mixed thoroughly.

Cerium is a metal, which was discovered in 1803 by Berzelius and Hisinger, and about the same time by Klaproth, who, however, described it as an earth. By the two former chemists it was recognized as a metal, and named cerium in honor of the goddess Ceres. It was obtained from a Swedish mineral, formerly from its great weight called *heavy stone of Bastnas* (*Bastnas Schwerstein*), but now named *cerite*, after the metal extracted from it. Besides cerite, it has been found in several other minerals, as *gadolinite*, *orthite*, etc., in the north of Europe, a number of different minerals from Greenland, and *allanite* near Bethlehem, in Pennsylvania. It is not easy to obtain it pure in the metallic state, as its oxides and salts are difficult of reduction. Berzelius describes it as in the form of pulverulent masses, of a deep chocolate-brown, which exhibit, however, under the burnisher a metallic appearance and a dark-gray color. Hildebrand and Norton have since prepared it in large quantity by the electrolysis of its chloride. It is a bad conductor of electricity. Heated in the air it takes fire before the point of ignition, and burns vividly, passing to the state of peroxide. At ordinary temperatures it is oxidized in a moist atmosphere, giving out a strong and disagreeable smell of hydrogen. In water, especially when moderately heated, it rapidly oxidizes, with the evolution of hydrogen, and the water does not become alkaline. There are two cerium oxides formerly considered as the protoxide and sesquioxide. (According to more recent investigators, cerium forms a sesquioxide and a dioxide only, so that cerous oxalate, which is the official salt, is an oxalate of the sesquioxide, a fact recognized in the Pharmacopœia of 1880.) Sulphur and phosphorus combine with it. Of its compounds two only have been introduced into medicine, the nitrate and the oxalate.

Cerium oxalate may be obtained from cerite, and Prof. F. F. Mayer, of New York, gives a process for the purpose, of which the following is an outline. The mineral consists of cerium, lanthanum, and didymium silicates, with numerous other substances in smaller proportion, the cerium oxide constituting about 39 per cent. of the whole. The powdered mineral is made into a paste with sulphuric acid, and then heated over a lamp until the mass ceases to swell and no longer absorbs sulphuric acid very cautiously added. Upon the cooling of the mass, it is powdered, and exposed in a crucible to the heat of an anthracite fire until it assumes a pale brownish-red color. It is now lixiviated first with hot water and then with nitric acid, and the solution treated with hydrogen sulphide in order to get rid of various metals by precipitation. To the clear liquid some hydrochloric acid is first added, and then a solution of oxalic acid, the former of which holds in solution the calcium oxalate produced, the latter throws down cerium oxalates and oxalates of other metals. The precipitate, having been washed with warm water, is formed into a paste with a quantity of magnesium carbonate equal to half that of the mineral employed; and the paste is dried on porous fire-brick, finely powdered, and calcined till it becomes of a cinnamon color. It now contains all of the cerium in the form of ceroso-ceric oxide. To separate this the mass is treated with an excess of nitric acid, the solution evaporated to get rid of the excess of acid, then diluted with warm water, and lastly poured into a vessel containing boiling water acidulated with a little more than half of one per cent. of sulphuric acid. A yellow precipitate of basic cerium sulphate is formed, while a little of the neutral sulphate, and all the lanthanum and didymium, remain dissolved. The precipitate is now dissolved in stronger sulphuric acid, the solution digested with a few crystals of sodium hyposulphite, in order to reduce the cerium ceroso-ceric oxide to cerous oxide, and the liquid, having been filtered, is treated with solution of oxalic acid, which causes a precipitate of cerium oxalate. This is washed with warm water, and dried. (*A. J. P.*, 1860, p. 4.)

Cerium oxalate is "a white, granular powder, without odor or taste, and permanent in the air. Insoluble in water, alcohol, ether, or in solutions of potassium or sodium hydrate; soluble in diluted sulphuric or hydrochloric acid. When heated to redness, it is decomposed, leaving a residue of reddish-yellow ceric oxide (a brown color would indicate the presence of *didymium*). On boiling the salt with potassium or sodium hydrate test-solution, white cerous hydrate is left as insoluble residue, while in the filtrate, supersaturated with acetic acid, calcium chloride test-solution will produce a white precipitate insoluble in acetic acid, but soluble in hydrochloric acid. If the yellow residue, left after heating, be dissolved in concentrated sulphuric acid, and a small crystal of strychnine added, a deep blue color will appear, which will rapidly change to purple and then to red. From the solution in diluted hydrochloric or sulphuric acid, potassium hydrate test-solution precipitates white, cerous hydrate, which does not redissolve in an excess of the reagent, and gradually turns yellow in contact with air. Ammonium carbonate test-solution precipitates white, cerous carbonate, which is somewhat soluble in an excess of the reagent. If 0·1 Gm. of Cerium Oxalate be dissolved in 1 C.c. of sulphuric

acid, and 2 C.c. of potassium sulphate test-solution be added, small, colorless crystals of cerium potassium sulphate will be deposited after some time. No effervescence should occur when the salt is dissolved in diluted hydrochloric acid (absence of *carbonate*); nor should the solution be colored or rendered turbid on the addition of an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, etc.). On boiling the salt with potassium or sodium hydrate test-solution and filtering, no precipitate should be produced in the filtrate either by ammonium chloride test-solution (absence of *aluminum*), or by ammonium sulphide test-solution (absence of *zinc*)." *U. S.* As usually seen in commerce it has a pinkish tinge, due to the presence of a trace of a compound of didymium. The British Pharmacopœia states that it is "An almost white granular powder, insoluble in *water*, decomposed at a dull red heat, yielding a reddish-brown powder which dissolves completely and without effervescence in boiling *hydrochloric acid;* the resulting solution gives with a saturated solution of *potassium sulphate* a white crystalline precipitate. When incinerated it loses 53 per cent. in weight. It should yield no characteristic reaction with the tests for arsenium, iron, aluminium, zinc, calcium, carbonates, or phosphates."

Medical Properties. Cerium oxalate is supposed to act in a manner very similar to bismuth subnitrate. It was originally brought forward by Sir James Y. Simpson as a remedy in the *vomiting of pregnancy*, and has been extensively used in this affection, and also in gastric disturbances of various diseases, such as *phthisis*, *uterine disorder*, *hysteria*, *dyspepsia*, *pyrosis*, etc. To a less extent it has been used in intestinal inflammatory diseases. Prof. Simpson also considered it to be a good nervine tonic, and used it with asserted great advantage in *chorea*. The dose is a grain (0·065 Gm.), doubled if necessary, and repeated three times a day, or more frequently if a return of the vomiting should seem to require it. It may be given in pill or suspended in water.

Cerium nitrate has also been employed, though not official. Prof. Simpson believed it to be a nervine tonic, and also useful in *irritable dyspepsia* and *chronic vomiting*. The dose is the same as that of the oxalate, though it would be prudent to begin with a smaller quantity, as, being a soluble salt, it might be more disposed to irritate in overdoses.

CETACEUM. U. S., Br. Spermaceti.

(CĒ-TĀ'CĒ-ŬM.)

"A peculiar, concrete, fatty substance, obtained from Physeter macrocephalus, Linné (class, Mammalia; order, Cetacea)." *U. S.* "A concrete fatty substance, obtained, mixed with oil, from the head of the Sperm Whale, Physeter macrocephalus. It is separated from the oil by filtration and pressure, and afterwards purified." *Br.*

Ambre Blanc, Blanc de Baleine, Spermacéti, Cétine, *Fr.;* Wallrath, Spermacetis, *G.;* Spermaceti, *It.;* Esperma de Ballena, *Sp.*

The spermaceti whale is from sixty to eighty feet long, with an enormous head, not less in its largest part than thirty feet in circumference, and constituting one-third of the whole length of the body. The upper part of the head is occupied by large cavities, separated by cartilaginous partitions, and containing an oily liquid, which, after the death of the animal, concretes into a white spongy mass consisting of spermaceti mixed with oil. This mass is removed, and the oil allowed to separate by draining. The crude spermaceti obtained from a whale of the ordinary size is more than sufficient to fill twelve large barrels. It still contains much oil and other impurities, from which it is freed by expression, washing with hot water, melting, straining, and repeated washing with a weak boiling potash lye. Common whale oil and the oil of other cetaceous animals contain small quantities of spermaceti, which they slowly deposit on standing.*

Spermaceti is in white, pearly, semi-transparent masses; of a neutral reaction; of a crystalline foliaceous texture; friable, soft, and somewhat unctuous to the touch; slightly odorous; insipid; of the sp. gr. 0·943; fusible at 44·5° C. (112° F.) (*Bostock*), 43·9° C. to 50° C. (111° F. to 122° F.) (*Br.*); volatilizable at a high temperature without change, *in vacuo*, but partially decomposed if the air is admitted; inflammable; insoluble in water; soluble in small proportion in boiling alcohol, ether, and oil of turpentine, but deposited as the liquids cool; and in the fixed oils; not affected by the mineral acids, except sulphuric, which decomposes and dissolves it;

* According to W. Gilmour, *sperm oil* should contain not less than 4 per cent. of cetin, and if much less be obtained by the following process, adulteration has been practised. Shake one part by weight of sulphuric acid (sp. gr. 1·84) with four parts of the oil; allow to stand 20 minutes, shaking twice; add 3 ounces of distilled water; shake this thoroughly, and allow to stand from 16 to 20 hours; dilute with 3 or 4 times its volume of distilled water; agitate thoroughly. On standing, the cetin floats upon the top, and can readily be skimmed off, washed, dried, and weighed. (*P. J. Tr.*, vii. 328. See also *Chem. Zeit.*, 1893, 1453, and *Amer. Drug.*, 1895, 105.)

rendered yellowish and rancid by long exposure to hot air, but capable of being again purified by washing with a warm lye of potash. "Specific gravity, about 0·945 at 15° C. (59° F.). It melts near 50° C. (122° F.), and congeals near 45° C. (113° F.). Insoluble in water, and nearly so in cold alcohol; soluble in boiling alcohol; also in ether, chloroform,* carbon disulphide, fixed and volatile oils; only slightly soluble in cold benzin. An alcoholic solution of Spermaceti is neutral to litmus paper. If 1 Gm. of Spermaceti be boiled with 1 Gm. of anhydrous sodium carbonate and 50 C.c. of alcohol, and the mixture cooled and filtered, the filtrate, upon being supersaturated with acetic acid, may become turbid, but should not afford a precipitate (absence of *stearic acid*)." *U. S.* The British Pharmacopœia states that "It is reducible to powder by the aid of a little *alcohol* (90 per cent.). It is insoluble in *water*, and nearly insoluble in cold *alcohol* (90 per cent.), but soluble in *ether*, *chloroform*, boiling *alcohol* (90 per cent.), and in fixed and volatile oils. Melting point 114·8° to 122° F. (46° to 50° C.) when tested by the method described under 'Cera Flava.' 0·2 gramme dissolved, by the aid of a water-bath, in 20 cubic centimetres of *alcohol* (90 per cent.), two drops of *solution of phenol-phthalein* being added, should not require more than one drop of *volumetric solution of sodium hydroxide* to produce a permanent red color (limit of acidity). Boiled with *alcohol* (90 per cent.), and the mixture cooled and filtered, the filtrate should not afford a flocculent precipitate on the addition of *water* (absence of stearic acid)." As found in commerce it is not chemically pure, containing a fixed oil, and often a peculiar coloring principle. From these it is separated by boiling in alcohol, which on cooling deposits it in crystalline scales. Thus purified, it does not melt under 49° C. (120° F.), is soluble in 40 parts of boiling alcohol of the sp. gr. 0·821 (Thénard), and is harder, more shining, and less unctuous than ordinary spermaceti. Spermaceti is a mixture of various fats. When recrystallized from alcohol as just described, the purified *cetin* is obtained, while the alcohol on evaporation deposits an oil (mechanically admixed sperm oil), the *cetinelaine* of Berzelius, which saponified yields *cetinelaic acid*, an acid resembling but distinct from oleic acid. The cetin which crystallizes out of the alcohol is essentially *cetyl palmitate*, $C_{16}H_{33}(C_{16}H_{31}O_2)$.—that is, a compound of *cetyl alcohol* (*ethal* of Chevreul), $C_{16}H_{33}.OH$, and *palmitic acid*, $C_{16}H_{32}O_2$. According to Heintz, however, there are small amounts of other fats with the cetin; fats containing the acids *stearic*, $C_{18}H_{36}O_2$, *myristic*, $C_{14}H_{28}O_2$, and *lauro-stearic*, $C_{12}H_{24}O_2$, and the alcohol radicals corresponding to these acids.

L. F. Kebler, after examining about twenty samples of spermaceti, found that commercial specimens have a melting point of from 42° to 47° C., a specific gravity ranging from 0·905 to 0·945 at 15° C., and saponification numbers from 125·8 to 134·6. He believes that the official requirements are those for cetin, and not spermaceti. (*A. J. P.*, 1896, 7, and 1897, 104.)

Medical Properties and Uses. Spermaceti has been given as a demulcent in irritations of the mucous membranes; but it has no remedial properties. It may be reduced to powder by the addition of a little alcohol or almond oil, or by melting it at a very low heat, pouring into a warm mortar, and agitating it until perfectly cold; an emulsion may be conveniently made by mixing the spermaceti first with half its weight of olive oil, then with powdered gum arabic, and lastly with water gradually added. It enters into many ointments and cerates.

CETRARIA. U. S. Cetraria. [Iceland Moss.]

(CĒ-TRĀ′RI-Ą.)

"Cetraria islandica (Linné), Acharius (class, Lichenes)." † *U. S.*

Iceland Lichen; Lichen Islandicus, *P. G.;* Mousse d'Islande, Lichen d'Islande, *Fr.;* Isländisches Moos, Isländisches Flechte, Lungenmoos, *G.:* Lichene islandico, *It.;* Liquen islandico, *Sp.:* Iceland Lichen.

Gen. Ch. Plant cartilagino-membranous, ascending or spreading, lobed, smooth, and naked on both sides. *Apothecia* shield-like, obliquely adnate with the margin, the disk colored, planoconcave; border inflexed, derived from the frond. *Loudon's Encyc.*

* In consequence of its solubility in chloroform, stains made by dropping it on cloth, or the grease-spots from burning candles, may be quickly removed by that liquid.

† Poisonous properties are very rare among the great cryptogamic family of Lichens. The *Cetraria juniperina* of Europe is said to be sometimes used as a poison for foxes; whilst the *wolf's moss* (*Ulfmossa*) of the north of Europe contains *vulpinic acid*, $C_{19}H_{14}O_5$, which has been found by Kobert to be an active protoplasmic poison: in frogs it produces tetanus, convulsions, and paralysis of central origin; in mammals it causes dyspnœa, vomiting, trembling, and a slowing of the pulse, with rise of the blood-pressure due to stimulation of the respective nerve-centres. After death the blood is not coagulable, and the secreting kidney-cells are found covered with a crystalline or amorphous mass of a vulpinate. No difference of action exists between vulpinic acid derived from wolf's moss and that synthetically produced. From *Cetraria pinastrin* Professor Zopf has separated *pinastrinic acid*, which seems to be very closely allied to vulpinic acid. (*Sitzungsb. der Dorpat. Naturforsch.-Gesellschaft*, 1892.)

Cetraria Islandica. Acharius, *Lichenog. Univ.* 512; *B. & T.* 302.—*Lichen islandicus.* Woodv. *Med. Bot.* p. 803, t. 271. Iceland moss is foliaceous, erect, from two to four inches high, with a dry, coriaceous, smooth, shining, laciniated frond or leaf, the lobes of which are irregularly subdivided, channelled and fringed at their edges with rigid hairs. Those divisions upon which the fruit is borne are dilated. The color is olive-brown or greenish gray above, reddish at the base, and lighter on the under than on the upper surface. The fructification is in flat, shield-like, reddish-brown receptacles, with elevated entire edges, placed upon the surface of the frond near its border. The plant is found in the northern latitudes of the old and new continents, and on the elevated mountains farther south. It received its name from the abundance with which it prevails in Iceland. It is also abundant on the mountains and sandy plains of New England. "It should be free from pine leaves, mosses, and other lichens, which are frequently found mixed with it." *U. S.*

The dried moss is of diversified color, grayish white, brown, and red, in different parts, with less of the green tint than in the recent state. It is officially characterized as follows. "From 5 to 10 Cm. long, foliaceous, irregularly branched into fringed and channelled lobes, brownish above, whitish beneath, and marked with small, depressed spots; brittle and inodorous; when softened in water, cartilaginous, and having a slight odor; its taste is mucilaginous and bitter." *U. S.* It is inodorous, and has a mucilaginous, bitter taste. Macerated in water, it absorbs rather more than its own weight of the fluid, and, if the water be warm, renders it bitter. Boiling water extracts all its soluble principles. The decoction thickens upon cooling, and acquires a gelatinous consistence, resembling that of starch in appearance, but without its viscidity. After some time the dissolved matter separates, and when dried forms semi-transparent masses, insoluble in cold water, alcohol, or ether, but soluble in boiling water, and in solution forming a blue compound with iodine. *Lichenin*, or *Lichen starch*, $C_{12}H_{20}O_{10}$, resembles starch in its general characters, but differs from it in some respects. Berzelius found in 100 parts of Iceland moss 1·6 of chlorophyll, 3·0 of a peculiar bitter principle, 3·6 of uncrystallizable sugar, 3·7 of gum, 7·0 of extractive, 44·6 of the peculiar starch-like principle, 1·9 of calcium and potassium lichen-stearates mixed with calcium phosphate, and 36·2 of amylaceous fibrin—the excess being 1·6 parts. Lichenin has been found to consist of two distinct proximate principles, for one of which the name lichenin may be retained, while for the other no particular designation has been chosen, but which we may call *lichenoid*. According to Th. Berg (*Thèse de Dorpat*, 1872), cetraria yields 35·15 per cent. of the mixed principles, of which 20 per cent. is of lichenin, and 11·5 of the so-called lichenoid. To separate them, a decoction of the moss, concentrated to a small bulk, and still hot, is treated by alcohol. The lichenoid is deposited in flocculi, which gradually unite in a viscid mass. This, being washed by alcohol until it ceases to be bitter, and then dried, yields a light friable matter partly soluble in cold water, with which it forms a yellow, limpid solution. To deprive it of mineral and coloring substances, it is dissolved in a little water, and precipitated afresh by alcohol. Lichenin is insoluble in cold water, but swells up and easily dissolves in hot water. It is insoluble in alcohol and in ether. It is only tinged by iodine. Lichenoid is, on the contrary, colored blue by that reagent. It is in part dissolved in cold water; and the undissolved part is equally colored blue by iodine. It is, like lichenin, insoluble in alcohol and ether. Both substances have strong analogies with starch, yet are distinct. For a further account of these principles, see *Journ. de Pharm.*, 1873.

The name of *cetrarin* has been conferred on the bitter principle. The following process for obtaining it is that of Dr. Herberger. The moss, coarsely powdered, is boiled for half an hour in four times its weight of alcohol of 0·883. The liquid when cool is expressed and filtered, and treated with diluted hydrochloric acid, in the proportion of three drachms to every pound of moss employed. Water is then added in the quantity of about four times the bulk of the liquid, and the mixture left for a night in a closed matrass. The deposit which forms is collected on a filter, allowed to drain as much as possible, and submitted to the press. To purify it, the mass, while still moist, is broken into small pieces, washed with alcohol or ether, and treated with two hundred times its weight of boiling alcohol, which dissolves the cetrarin, leaving the other organic principles by which it has hitherto been accompanied. The greater part is deposited as the liquor cools, and the remainder may be obtained by evaporation. By this process one pound of moss yielded to Dr. Herberger 133 grains of cetrarin. This principle is white, not crystalline, light, unalterable in the air, inodorous, and exceedingly bitter, especially in alcoholic solution. Its best solvent is absolute alcohol, of which 100 parts dissolve 1·7 of cetrarin at the boiling temperature. Ether also dissolves it, and it is slightly soluble in water. Its solutions are quite neutral to test-paper. It is precipitated by the acids, and

rendered much more soluble by the alkalies. Concentrated hydrochloric acid changes its color to a bright blue. It precipitates the salts of iron, copper, lead, and silver. In the dose of two grains (0·130 Gm.) every two hours, it has been used successfully in intermittent fever. (*Journ. de Pharm.*, xxiii. 505.) Drs. Schnedermann and Knop have ascertained that the cetrarin above referred to consists of three distinct substances: 1, *cetraric acid*, $C_{18}H_{16}O_8$, which is the true bitter principle, crystallizable, and intensely bitter; 2, a substance resembling the fatty acids, called *lichen-stearic acid*, $C_{14}H_{34}O_3$, the crystals of which melt at 120° C. (248° F.); and, 3, a green coloring substance, which they name *thallochlor*. These principles are obtained perfectly pure with great difficulty. (*Ann. der Pharm.*, lv. 144.) Hilger and Buchner (*Ber. der Deutsch. Chem. Ges.*, 1890, p. 461) have extracted both lichen-stearic and cetraric acids and studied them more fully. They give to the former the formula $C_{43}H_{76}O_{13}$, and to the latter the composition $C_{30}H_{30}O_{12}$, and both are shown to be dibasic acids.

The gum and starch contained in the moss render it sufficiently nutritive to serve as food for the Lapps and Icelanders, who employ it powdered and made into bread, or boiled with milk, after having partially freed it from the bitter principle by repeated maceration in water. As suggested by Berzelius, the bitterness may be entirely extracted by macerating the powdered moss, for 24 hours, in twenty-four times its weight of a solution formed with 1 part of an alkaline carbonate and 375 parts of water, then decanting the liquid, and repeating the process with an equal quantity of the solution. The powder, being now dried, is perfectly sweet, and has been used to some extent in pharmacy as a substitute for acacia. It lacks one important quality of the latter, however,—*i.e.*, adhesiveness; and it must be entirely devoid of bitterness, if it is to be used for this purpose. (See also *Gelatina Lichenis Islandici Saccharata Sicca* (Germ. Unoff. Formulary), *Proc. A. P. A.*, 1892, 455.)

Medical Properties and Uses. Iceland moss is demulcent, nutritious, and tonic, and well calculated for affections of the mucous membrane of the lungs and bowels, with debility of the digestive organs, or of the system generally. Hence it has been found useful in *chronic catarrhs*, and other *chronic pulmonary affections* attended with copious puruloid expectoration, in *dyspepsia*, in *chronic dysentery* and *diarrhœa*, and in the *debility* succeeding acute disease, or dependent on copious purulent discharge from external *ulcers*. At one time it possessed much reputation as a remedy in *pulmonary consumption*. It had long been employed in this disease, and in *hæmoptysis*, by the Danish physicians, before it became generally known. In the latter half of the last century it came into extensive use, and numerous cures supposed to have been effected by it are on record. We now know that it can exercise no specific influence over the tuberculous affection; but as Prof. Kobert has found that cetrarin is a stimulant to the gastro-intestinal mucous membrane and to peristalsis, besides having a tendency to increase the formation of red and white blood corpuscles, it is easily seen how cetrarin may do good in *phthisis* as a demulcent tonic. Cetrarin itself has been commended in *chlorosis* or *debility*, with constipation; dose, 1·5 to 3 grains (0·1–0·2 Gm.). It is usually employed in the form of decoction. (See *Decoctum Cetrariæ*.) By some writers it is recommended to deprive it of the bitter principle by maceration in water or a weak alkaline solution, before preparing the decoction; but we thus reduce it to the state of a simple demulcent, or mild article of diet, in which respect it is not superior to the ordinary farinaceous or gummy substances used in medicine. The powder is sometimes given in the dose of thirty grains or a drachm (1·95–3·9 Gm.); and a preparation at one time obtained some repute, in which the ground moss was incorporated with chocolate, and used at the morning and evening meal as an ordinary beverage.

CHARTÆ. Papers.

(CHÄR'TÆ.)

Papiers sparadrapiques, *Fr.;* Medicamentirte Papiere, *G.*

This class of preparations, long official in the French Codex, was afterwards adopted into the British Pharmacopœia, but was not introduced into that of the United States until 1870.*

* *Charta Cantharidis.* A *blistering paper* was formerly recognized by the two Pharmacopœias, *Charta Cantharidis, U. S., Charta Epispastica, Br.;* but as these preparations were found inefficient, they have been very properly dropped from the official lists. The United States process (1880) is as follows: "White Wax, *eight parts* [or four ounces av.]; Spermaceti, *three parts* [or one and a half ounces av.]; Olive Oil, *four parts* [or two fluidounces]; Canada Turpentine, *one part* [or half an ounce av.]; Cantharides, in No. 40 powder, *one part* [or half an ounce av.]; Water, *ten parts* [or five fluidounces]. Mix all the substances in a tinned vessel, and boil gently for two hours, constantly stirring. Strain through a woollen strainer without expressing, and, by means of a water-bath, keep the mixture in a liquid state in a shallow, flat-bottomed vessel with an extended surface. Coat strips of sized paper with the melted plaster, on one side only, by passing them successively over the surface of the liquid; when dry, cut the strips into rectangular pieces."

CHARTA POTASSII NITRATIS. U. S. Potassium Nitrate Paper.

(CHÄR'TĄ PŌ-TĂS'SĮ-Ī NĪ-TRĀ'TĬS.)

Papier nitré, *Fr.*

"Potassium Nitrate, *two hundred grammes* [or 7 ounces av., 24 grains]; Distilled Water, *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]. Dissolve the Potassium Nitrate in the Distilled Water. Immerse strips of white, unsized paper in the solution, and dry them. Keep the paper in well-closed vessels." *U. S.*

This preparation is identical with the *Charta Nitrata* of the German Pharmacopœia; it is sometimes called *asthma paper*. Care should be taken to dissolve thoroughly all of the nitrate, so that it shall not be deposited upon the paper in large particles and interfere with slow and steady combustion.

Medical Properties. This paper is an excellent remedy, which in many cases of *asthma* affords much relief. It is used by burning it in front of the patient, who inhales its fumes. Its efficacy is much increased by saturating it with fluid extract of belladonna and drying. Paper thus prepared must be used with some caution.

CHARTA SINAPIS. U. S., Br. Mustard Paper.

(CHÄR'TĄ SĮ-NĀ'PĬS.)

Papier sinapisé, *Fr.*; Senfpapier, *G.*

Black Mustard, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 230 grains]; India-Rubber, *ten grammes* [or 154 grains]; Benzin, Carbon Disulphide, each, *a sufficient quantity*. Pack the Black Mustard in a conical percolator, and gradually pour Benzin upon it until the percolate ceases to produce a permanent, greasy stain upon blotting paper. Remove the powder from the percolator, and dry it by exposure to the air. Having meanwhile dissolved the India-Rubber in a mixture of *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], each, of Benzin and Carbon Disulphide, mix the purified Mustard with a sufficient quantity of the solution to produce a semi-liquid magma, and apply this, by means of a suitable brush, to one side of a piece of rather stiff, well-sized paper, so as to cover it completely, and then allow the surface to dry. A surface of sixty square centimeters should contain about 4 grammes of Black Mustard deprived of oil. Before it is applied to the skin, Mustard Paper should be dipped in warm water for about fifteen seconds." *U. S.*

"Black and White Mustard Seeds, equal proportions by weight; Benzol, Solution of India-rubber, of each, a sufficient quantity. Bruise the Mustard Seeds and extract the fixed oil by percolation with the Benzol. Dry the residue by exposure to the air in a warm closet, and reduce to No. 60 powder. Mix seventy-five grains (or five grammes) of the purified mustard with five fluid drachms (or eighteen cubic centimetres) of Solution of India-rubber, and spread by means of a suitable brush over about 30 square inches (or about two square decimetres) of one side of a piece of cartridge paper. Allow it to dry by exposure to the air." *Br.*

The formula for this preparation has been greatly improved by the U. S. P. 1890 and B. P. 1898. The British preparation (1885) was at fault in not providing for the extraction of the fixed oil by previously percolating with benzin or carbon disulphide; otherwise the paper will be greasy, giving to the plaster an untidy appearance and soiling the linen of the patient. Solution of gutta-percha is unsuited for use in this preparation, on account of want of adhesiveness, and the tendency of the mixture, when dry, to crack and peel off. We have used instead a solution of 1 part of pure rubber in 30 of equal parts of carbon disulphide and benzin. On the large scale, by means of a plaster-spreading apparatus a uniform coat of this solution may be applied to paper. As the latter passes out from under the apparatus, a sieve containing the powdered mustard is shaken over it; this is fixed by the adhesive coat and firmly retained after the evaporation of the volatile liquids in a warm place. The application of the powdered mustard must be properly regulated according to the speed with which the machine delivers the coated paper. The paper is cut into pieces of convenient size, and needs only to be wetted with *tepid* water to be ready for use. Owing to the fact that the large manufacturers can put mustard paper upon the market at such low rates that it pays the apothecary better to buy than to prepare it, Charta Sinapis, so far as we can learn, is rarely made in the retail stores. Experience has shown that the ready-made mustard papers err rather from too much than from too little activity. Moreover, their action cannot be regulated with the same nicety as can that of the mustard poultice. Unless in the case of travellers, and of others who must wait upon themselves, the domestic application is preferable. The mustard leaves can rarely be borne for more than ten or fifteen minutes.

CHELIDONIUM. U. S. Chelidonium. [Celandine.]

(ĈHĔL-Ị-DŌ'NỊ-ŬM.)

"The entire plant, Chelidonium majus, Linné (nat. ord. Papaveraceæ)." *U. S.*

Herba Chelidonii, *P. G.*; Tetterwort; Chélidoine, Herbe à l'Hirondelle, *Fr.*; Schöllkraut, *G.*

Celandine is a perennial herbaceous plant, growing wild in this country, about old houses and in rocky places; supposed to have been introduced from Europe, where it is indigenous. It is one or two feet high, bears pinnate leaves and small peduncled umbels of yellow flowers, and when wounded emits a yellow, opaque juice. The whole plant is used. It has a faint unpleasant odor, and a bitter, acrid, durable taste, which is stronger in the roots than in the leaves. The odor is nearly lost by drying, but the taste remains. The yellow juice is bitter and exceedingly acrid, and when applied to the skin produces inflammation and even vesication. It is officially described as follows: "Root several-headed, branching, reddish-brown; stem about 50 Cm. long, light green, hairy; leaves about 15 Cm. long, thin, petiolate, the upper ones smaller and sessile, light green, on the lower side glaucous, lyrate-pinnatifid, the pinnæ ovate-oblong, obtuse, coarsely crenate or incised and the terminal one often three-lobed; flowers in small, long-peduncled umbels with two sepals and four yellow petals; capsule linear, two-valved and many-seeded. The fresh plant contains a saffron-colored milk-juice, and has an unpleasant odor and acrid taste." *U. S.*

Dr. Probst, of Heidelberg, found in it a peculiar acid denominated *chelidonic acid;* two alkaline principles, one of which forms neutral salts with the acids, and is called *chelerythrine* in consequence of the intense redness of its salts, the other unites with but does not neutralize the acids, and is named *chelidonine;* and lastly a neutral crystallizable, bitter principle, which from its yellow color he calls *chelidoxanthin.* Orlow believes, however, that the latter is an alkaloid, and gives a process for its preparation in *Pharm. Zeit. f. Russ.*, 1893, No. 21. Chelerythrine appears to be an acrid narcotic poison. (*Annal. der Pharm.*, xxix. 113.) It has been shown by Dr. James Schiels, of St. Louis, to be identical with *sanguinarine*, and may be prepared in the same manner. (See *Sanguinaria.*) Zwenger isolated another acid, which he names *chelidoninic acid*, although both Walz and Kraut consider it to be only succinic acid. (*A. J. P.*, 1861, 7.) Schmidt considers chelidoninic acid to be identical with ethylene-succinic acid. (*Arch. d. Pharm.*, 1886, 531.) For color tests for chelidonine, see *Proc. A. P. A.*, 1895, 992. *Chelidonine phosphate*, *chelidonine sulphate*, and *chelidonine tannate* have been used medicinally. (See *Proc. A. P. A.*, 1897, 721.)

Subsequently (1889) Prof. Schmidt announced the presence of twelve different bases, four of which he has studied: *chelidonine*, $C_{20}H_{19}NO_5 + H_2O$; *methylchelidonine;* *α-methylchelidonine* and *β-methylchelidonine*, represented by the formula $C_{21}H_{21}NO_5$. These bases were ascertained to possess physiologically an action resembling that of morphine. (*Pharm. Zeit.*, 1889, p. 582.) Schmidt (*A. J. P.*, 1890, p. 13) also found *protopine*, and showed the identity of stylophorine, from *Stylophorum diphyllum*, with chelidonine. This last result was confirmed by Selle. (*A. J. P.*, 1890, p. 176.) Selle later (*Arch. der Pharm.*, 1890, 441–462) sums up the composition of *Chelidonium majus* as follows: it contains, besides chelidonine and chelerythrine, three other alkaloids, called *α-homochelidonine*, $C_{21}H_{21}NO_5$, *β-homochelidonine*, $C_{21}H_{21}NO_5$, and *protopine.* These results practically agree with those before obtained by Schmidt. The identity of chelerythrine and sanguinarine is not conceded by G. König. (*Chem. Centralbl.*, 1891, p. 321.) He gives the composition $C_{21}H_{17}NO_4$ to the former and $C_{20}H_{15}NO_4$ to the latter, making one the methyl derivative of the other.

Medical Properties and Uses. Celandine is an acrid purgative, possessed also of diuretic, and perhaps diaphoretic and expectorant, properties. In overdose it produces uncertain effects and has been ranked as doubtfully poisonous. A case in which a fatal result was attributed to the hypodermic injection of half a gramme of the extract is reported in the *Zeitsch. f. Medizinalbeamte*, 1898; but a careful study of the detailed report is convincing that the remedy had nothing to do with the death. By the ancients chelidonium was esteemed in *jaundice*, and was indeed the chief ingredient of the old *decoctum ad ictericos* of the Edinburgh Pharmacopœia. It has been given also in other complaints, especially those of a *scrofulous character* affecting the mesenteric and lymphatic glands, the skin, and the eyes. The yellow juice is distinctly irritant, and has long been used as a local application to *corns*, *warts*, and other hypertrophic lesions of the skin, as well as in *chronic eczema* and *urticaria.* Denissenko asserts that he has obtained very favorable results in external *cancers* by the internal administration of from twenty-four to seventy-five grains of the extract, conjoined with the injection at

the border of the tumor of a mixture of equal parts of the extract, distilled water, and glycerin; but it is not probable that this treatment is of any value when the growth is really malignant. The dose of the dried root or herb is from thirty grains to a drachm (1·9–3·9 Gm.), that of the fresh root one or two drachms (3·9–7·8 Gm.), and the same quantity may be given in infusion. The dose of the aqueous extract is from five to ten grains (0·324 to 0·648 Gm.), of the expressed juice from ten to twenty drops (0·648 to 1·29 C.c.), to be gradually increased. The allegation of Peronin that *chelidonine sulphate*, in doses of from 0·05 to 0·3 grain, is an active analgesic and somnifacient has not been confirmed by subsequent observers.

CHENOPODIUM. U. S. Chenopodium. [American Wormseed.]

(ĶHĒ-NŌ-PŌ'DI-ŬM.)

"The fruit of Chenopodium ambrosioides, Linné, and variety anthelminticum, Gray (nat. ord. Chenopodiaceæ)." *U. S.*

Fructus Chenopodii Anthelmintici; Semences de Chénopode anthelmintique, *Fr.;* Amerikanischer Wurmsamen, *G.*

Gen. Ch. Calyx five-leaved, four-cornered. *Corolla* none. *Seed* one, lenticular, superior. *Willd.*

Chenopodium anthelminticum. Willd. *Sp. Plant.* i. 1304; Barton, *Med. Bot.* ii. 183; *B. & T.* 216. This is an indigenous perennial plant, with an herbaceous, erect, branching, furrowed stem, which rises from two to five feet in height. The leaves are alternate or scattered, sessile, oblong-lanceolate, attenuated at both ends, sinuated and toothed on the margin, conspicuously veined, of a yellowish-green color, and dotted on their under surface.* The flowers are very numerous, small, of the same color with the leaves, and arranged in long, leafless, terminal panicles, composed of slender, dense, glomerate, alternating spikes.

This species of Chenopodium, known commonly by the names of *wormseed* and *Jerusalem oak*, grows in almost all parts of the United States, but most vigorously and abundantly in the southern section. It is usually found in the vicinity of rubbish, along fences, in the streets of villages, and in open grounds about the larger towns. It flowers from July to September, and ripens its seeds successively through the autumn. The whole herb has a strong, peculiar, offensive, yet somewhat aromatic odor, which it retains when dry. All parts of the plant are occasionally employed; but only the fruit is official. This should be collected in October.†

Wormseed, as found in commerce, is in small grains, not larger than the head of a pin, irregularly spherical, very light, of a dull greenish-yellow or brownish color, a bitterish, somewhat aromatic, pungent taste, and possessed in a high degree of the peculiar smell of the plant. These grains, when deprived, by rubbing them in the hand, of a capsular covering which invests the proper seed, exhibit the shining, blackish surface of the obtusely-edged seed. They abound in a volatile oil, upon which their sensible properties and medical virtues depend, and which is obtained by distillation. (See *Oleum Chenopodii.*) The same oil impregnates to a greater or less extent the whole plant.

Medical Properties and Uses. Wormseed is one of our most efficient indigenous anthelmintics, and is thought to be particularly adapted to the expulsion of the *round worms* in children. A dose of it is usually given before breakfast in the morning, and at bedtime in the evening, for three or four days successively, and then followed by calomel or some other brisk cathartic. If the worms are not expelled, the same plan is repeated. The medicine is most conveniently administered in powder, mixed with syrup, in the form of an electuary. The dose for a child two or three years old is from one to two scruples (1·3–2·6 Gm.). The volatile oil is more frequently given than the fruit in substance; though its offensive odor and taste sometimes render it difficult of administration. The dose for a child is from five to ten drops (0·3–0·6 C.c.) mixed with sugar, or in the form of emulsion. The oil of wormseed is probably in overdoses capable of acting as a poison. Dr. A. K. Bond has reported the death, preceded by stupor, of a boy three years old, as caused by a half-drachm. (*Maryland Med. Journ.*, 1897.) A tablespoonful (15 C.c.) of the expressed juice of the leaves, or a wineglassful (60 C.c.) of the decoction prepared by boiling an ounce of the fresh plant in a pint of milk,

* Dr. H. Paschkis has made an elaborate study of the microscopic structure of this leaf. (*P. J. Tr.*, 1881, p. 44.)

† *C. anthelminticum* is cultivated to a considerable extent in Maryland, twenty or thirty miles north of Baltimore. The seeds are sown in small beds of rich mould early in spring, and during the month of June the young plants are pulled up, and set out in ridges three feet apart, with intervals of from six to ten inches. The plants do not require to be renewed oftener than once in four or five years. The crop of the second year is more productive than that of the first. The plant is fit for distillation during the first half of September. The distillation is carried on in the same neighborhood. The whole herbaceous part of the plant is used. It is said to yield from 1·5 to 2 per cent. of the oil, and the produce of an acre will yield 20 pounds. (See *A. J. P.*, xxii. 304.)

with the addition of orange-peel or other aromatic, is sometimes substituted in domestic practice for the fruit and oil.

The fruit of *Chenopodium ambrosioides*, which is very prevalent in the Middle States, is said to be used indiscriminately with that of *C. anthelminticum*, and to be employed in Brazil, under the name of *Herba Santa Maria*, as an anthelmintic and in pectoral complaints (*P. J. Tr.*, ix. 713); also in Europe in nervous affections, particularly *chorea* (a cupful of an infusion (℥ii to f℥x) morning and evening). It may be distinguished by its odor, which is weaker and less offensive, and to some persons agreeable. The plant itself is often confounded with the true wormseed, from which it differs in having its flowers in leafy racemes.

C. Botrys, or *Jerusalem oak*, is another indigenous species, possessing anthelmintic virtues. It is said to have been used in France with advantage in *catarrh* and *asthma*.

CHIMAPHILA. U. S. Chimaphila. [Pipsissewa.]

(ĪHI-MĂPH'I-LĄ.)

"The leaves of Chimaphila umbellata (Linné), Nuttall (nat. ord. Ericaceæ.)" *U. S.*

Prince's Pine, Winter-green; Herbe de Pyrole ombellée, *Fr.*; Doldenblüthiges Harnkraut, Wintergrün, *G.*

Gen. Ch. Calyx five-toothed. *Petals* five. *Style* very short, immersed in the germ. *Stigma* annular, orbicular, with a five-lobed disk. *Filaments* stipitate; stipe discoid, ciliate. *Capsules* five-celled, opening from the summits, margins unconnected. *Nuttall.*

This genus was separated from *Pyrola* by Pursh. It embraces two species, *C. umbellata* and *C. maculata*, which are both indigenous, and known by the common title of *winter-green*. The generic title is formed of two Greek words, χεῖμα, winter, and φίλος, a friend.

Chimaphila umbellata. Barton, *Med. Bot.* i. 17; Carson, *Illust. of Med. Bot.* i. 62, pl. 53.—*Pyrola umbellata.* Willd. *Sp. Plant.* ii. 622; Bigelow, *Am. Med. Bot.* ii. 15.—*Chimaphila corymbosa.* Pursh. *B. & T.* 165. The pipsissewa is a small evergreen plant, with a perennial, creeping, yellowish root (rhizome), which gives rise to several simple, erect or semiprocumbent stems, from four to eight inches in height, and ligneous at their base. The leaves are wedge-shaped, somewhat lanceolate, serrate, coriaceous, smooth, of a shining, sap-green color on the upper surface, paler beneath, and supported upon short footstalks, in irregular whorls, of which there are usually two on the same stem. The flowers are disposed in a small terminal corymb, and stand upon nodding peduncles. The calyx is small and divided at its border into five teeth or segments. The corolla is composed of five roundish, concave, spreading petals, which are of a white color tinged with red, and exhale an agreeable odor. The stamens are ten, with filaments shorter than the petals, and with large, nodding, bifurcated, purple anthers. The germ is globular and depressed, supporting a thick and apparently sessile stigma, the style being short and immersed in the germ. The seeds are numerous, linear, chaffy, and enclosed in a roundish, depressed, five-celled, five-valved capsule, having the persistent calyx at the base. This humble but beautiful evergreen is a native of the northern latitudes of America, Europe, and Asia. It is found in all parts of the United States. It grows under the shade of woods, and prefers a loose sandy soil enriched by decaying leaves. The flowers appear in June and July. All parts of the plant are endowed with active properties. The leaves and stems are found in commerce. The leaves are officially described as "about 5 Cm. long, oblanceolate, sharply serrate above, wedge-shaped and nearly entire towards the base; coriaceous, smooth, and dark green on the upper surface. It is nearly inodorous, and has an astringent and bitterish taste." *U. S.*

C. maculata, or *spotted winter-green*, though not official, probably possesses similar virtues. The character of the leaves of the two plants will serve to distinguish them. Those of *C. maculata* are lanceolate, rounded at the base, where they are broader than near the summit, and of a deep olive green, veined with greenish white; those of the official species are broadest near the summit, gradually narrowing to the base, and of a uniform shining green.

Properties. Pipsissewa, when fresh and bruised, exhales a peculiar odor. The leaves have been already described. Their taste is pleasantly bitter, astringent, and sweetish; that of the stems and root unites with these qualities a considerable degree of pungency. Boiling water extracts the active properties of the plant, which are also imparted to alcohol. The leaves have been examined by Mr. Samuel Fairbank, who found in them gum, starch, sugar, extractive, pectic acid, tannic acid, resin, fatty matter, chlorophyll, yellow coloring matter, lignin, a peculiar whitish substance which he calls *chimaphilin*, and various inorganic substances, as potassa, lime, magnesia, sodium chloride, and sulphuric, phosphoric, and silicic acids. The

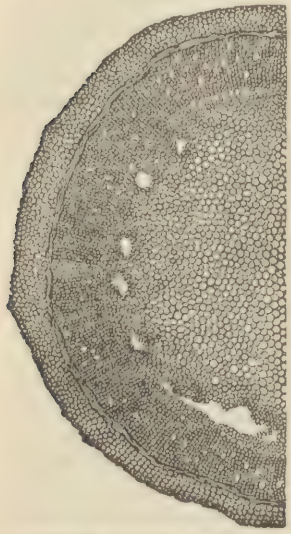
chimaphilin was obtained by agitating a tincture with chloroform, allowing the mixture to stand, removing the lighter liquid, and allowing the chloroformic solution to evaporate. A yellow crystalline substance was left, which, purified by solution in alcohol, filtration, and spontaneous evaporation, constituted the substance in question. It was also obtained by simply distilling the stems with water. It is in beautiful, golden-yellow, acicular crystals, inodorous, tasteless, fusible, volatilizable unchanged, insoluble or nearly so in water, soluble in alcohol, ether, chloroform, and the fixed and volatile oils, and possessed of neither acid nor alkaline properties. (*Journ. and Trans. of the Maryland Coll. of Pharm.*, 1860.) The active principle of the leaves seems to have been isolated by E. S. Beshore (*A. J. P.*, 1887, p. 125) by treatment of the powdered leaves with petroleum spirit. He obtained white crystals, melting at 236° C., sparingly soluble in cold or boiling 90-per-cent. alcohol, sparingly soluble in ether, benzin, chloroform, and cold glacial acetic acid; more soluble in hot glacial acetic acid. An ultimate analysis gave the formula $C_{10}H_{19}O$. He also obtained the golden-yellow crystalline principle of Fairbank both from the leaves and the stems. He considers it distinct from the one described above. Josiah C. Peacock (*A. J. P.*, 1892, p. 295) has made a careful analysis of both *C. umbellata* and *C. maculata*. He obtained in several ways the yellow crystalline principle *chimaphilin*, and studied its properties. It forms yellow acicular crystals, nearly odorless and tasteless, insoluble in water, soluble in alcohol, chloroform, ether, benzen, petroleum benzin, acetous and glacial acetic acid. They may be sublimed by careful heating without change. Chimaphilin melts at 108°–109° C., and has the composition $C_{24}H_{21}O_4$. Peacock also found three other crystalline principles, for which no formulas, however, are given. Ridenour (*A. J. P.*, 1895, 236) has also prepared chimaphilin, and by the analysis of the purified crystals and of two of its derivatives, confirms the formula, $C_{24}H_{21}O_4$, given by Peacock. He finds the melting point of the purified chimaphilin to be 114° C. He also prepared another crystalline principle melting above 250° C., to which he gives the formula $C_{10}H_{19}O$, which agrees with Beshore's product.

Medical Properties and Uses. This plant is stated to have been used internally by the North American Indians in *scrofula* and *rheumatism*, and was subsequently a very popular remedy among the settlers of this country. It is now known, however, to be only slightly tonic, astringent, and diuretic. It is one of the mildest and least effective of the so-called stimulating diuretics, being closely similar to, but less certain and effective than, uva ursi in its therapeutic influence and application. The best preparation is the official fluid extract, which may readily be made into a syrup. The does is two fluidrachms (7·5 C.c.).

CHIRATA. U. S., Br. Chirata.

(ĈHI-RĀ'TA.)

"The entire plant, Swertia Chirata, Hamilton (nat. ord. Gentianeæ)." *U. S.* "The dried plant, Swertia Chirata, Ham., collected when in flower." *Br.*



Chiretta; Chirette, *Fr.*; Chiretta, *G.*

Gen. Ch. Corolla withering, rotate, in æstivation twisted to the right; with glandular hollows protected by a fringed scale upon the segments. *Anthers* not changing. *Stigmas* sessile. *Capsules* conical; one-celled, with spongy placentæ upon the sutures. *Seeds* indefinite, minute. *Lindley.*

Agathotes chirayta. Don, *Lond. Philos. Mag.* 1836, p. 76.—*Gentiana chirayta.* Fleming, *Asiat. Research.* xi. 167.—*Ophelia Chirata.* Grisebach. *B. & T.* 183. The *chirayta*, or *chirata*, is an annual plant, about three feet high, with a branching root, and an erect, smooth, round stem, branching into an elegant leafy panicle, and furnished with opposite, embracing, lanceolate, very acute, entire, smooth, three- or five-nerved leaves. The flowers are numerous, peduncled, yellow, with a four-cleft calyx having linear acute divisions, the limb of the corolla spreading and four-parted, four stamens, a single style, and a two-lobed stigma. The capsules are shorter than the permanent calyx and corolla. The plant is a native of Nepaul and other parts of Northern India. The whole of it is gathered when the flowers begin to decay.*

* In the Indian bazaars the name chirata is applied to various dried gentianaceous plants; the most important of these is the *Ophelia angustifolia*. It yields the *Paharee* or *Hill chirata*, which is distinguished by its inferior bitterness, and its rectangular, winged stems, whose section presents a thick woody ring and a centre nearly or entirely hollow, with only traces of pith. A false chirata, which has also found its way into the London markets, and resembles the official variety in having a well-developed pith, but which is completely lacking in bitterness, is affirmed to be the product of *Ophelia alata*. (*P. J. Tr.*, xvii. 903.) Under the name of *Indian chirata*, the dried plant of the *Andrographis paniculata*, which is officially recognized by the Pharmacopœia of India, has appeared in the London market. It resembles much more closely recently dried broom-tops than the true chirata. It is a

The dried plant is imported into Europe in bundles, consisting mainly of the stems, with portions of the root attached. The stems contain a yellowish pith. The drug is officially described as a "root nearly simple, about 7 Cm. long; stem branched, nearly 1 meter long, slightly quadrangular above; containing a narrow wood-circle and a large yellowish pith. Leaves opposite, sessile, ovate, entire, five-nerved. Flowers numerous, small, with a four-lobed calyx and corolla. The whole plant smooth, pale brown, inodorous, and intensely bitter." *U. S.* Its fruits are superior, bicarpellary, and unilocular. Its virtues are imparted to water and alcohol, and are retained in the extract. According to Lassaigne and Boissel, the stems contain resin, a yellow bitter substance, brown coloring matter, gum, and various salts. Flückiger and Höhn, who subsequently examined the stems and roots of chirata, extracted from them sugar, wax, chlorophyll, soft resin, tannin, an acid which they name *ophelic*, possessing the formula $C_{13}H_{20}O_{10}$, and a peculiar bitter substance, denominated *chiratin*, $C_{26}H_{48}O_{15}$. The acid is syrupy, deliquescent, yellowish brown, at first slightly sour, afterwards intensely bitter. It is soluble in water, with some turbidness, probably owing to resin mixed with it, and completely soluble in alcohol, or a mixture of this with ether. It decomposes certain salts, and forms amorphous compounds with acids. Chiratin is a yellow, hygroscopic powder, but feebly crystallizable, very bitter, sparingly soluble in cold water, more so in hot water, and readily dissolved by alcohol and ether. It is neutral to test-paper, and yields a copious precipitate with tannic acid. By the action of acids, chiratin is separated into ophelic acid, and a yellowish-brown, amorphous substance, bitter, scarcely soluble in water, readily soluble in spirit, and not reducing copper solutions, as the ophelic acid does. Höhn gives it the formula $C_{13}H_{24}O_3$, and names it *chiratogenin*. (*P. J. Tr.*, Aug. 1870, 106.)

Chirata, transverse section.

Medical Properties and Uses. Chirata has long been used in India. It has been introduced into Europe, and appears to be highly esteemed, but has not been employed to any considerable extent in this country. Its properties are those of the pure bitters, and probably do not differ from those of the other members of the family of Gentianaceæ. (See *Gentiana*.) Like these, in overdoses it nauseates and oppresses the stomach. Some have supposed that, in addition to its tonic properties, it exerts a peculiar influence over the liver, promoting the secretion of bile and correcting it when deranged, and restoring healthy evacuations in cases of habitual costiveness. It has been used in *dyspepsia*, and in the *debility* of convalescence, and generally in cases in which corroborant measures are indicated. In India it has been successfully employed in *intermittents* and *remittents*, combined with the seeds of *Guilandina bonducella*. It may be given in powder, infusion, tincture, or fluid extract. The dose in substance is twenty grains (1·3 Gm.).

CHLORAL. U. S. (Br.) Chloral. Chloral Hydrate.

C_2HCl_3O, H_2O; 164·97. (KLŌ'RAL.) C_2HCl_3O, H_2O; 165·2.

"A crystalline solid, composed of Trichloraldehyde or Chloral with one molecule of water. It should be kept in glass-stoppered bottles, in a cool and dark place." *U. S.* "Chloral Hydrate, or trichlorethylidene glycol, $CCl_3.CH(OH)_2$, is obtained by the addition of water to the liquid chloral produced by the action of dry chlorine gas on ethylic alcohol." *Br.*

Chloral Hydras, *Br.*, Hydrous Chloral; Chloralum Hydratum Crystallisatum, *P. G.*; Hydrate de Chloral, *Fr.*; Chloral Hydrat, *G.*

In adopting the name chloral to designate chloral hydrate, the U. S. Pharmacopœia has unfortunately perpetuated an inaccuracy which neither the English, the Germans, nor the French follow in their usage, the term *hydrate* being always employed, as it should be. The fact that water is absolutely necessary to allow of the crystallization of the preparation, and to give it medicinal character, should be recognized in the name. As custom has sanctioned the usage here in the present article, whenever the term chloral is used, the hydrate is in-

little more than two feet long. The branching stems are from ⅛ to ¼ inch in thickness near the base, woody, quadrangular, furrowed, smooth, slightly knotted at the point from which the branches spring, the longitudinal furrows are continued through the roots, which have numerous fine radicles, the leaves are opposite decussate, branches erect or forming an acute angle with the stem, terminal shoots extremely slender.

tended; and whenever the uncombined substance is referred to, it is designated *anhydrous chloral*. Perhaps no medicine has come so rapidly into extensive use as that now under consideration. Though discovered by Liebig so long since as 1832, and afterwards investigated by Dumas, who determined its chemical formula, it was not until 1869 that its remedial properties were first made known by their discoverer, Dr. Otto Liebreich, of Berlin: in 1878 the consumption of chloral was estimated at one ton daily in England and America alone; and, although not used now to this extent, it is still largely employed.

Anhydrous Chloral. In preparing anhydrous chloral, the simple method originally employed by Liebig, of acting directly on alcohol by chlorine, is generally preferred, even, we believe, by the larger manufacturers; though a more complex proceeding has been suggested by Staedeler, of distilling together proximate vegetable principles, as fecula, sugar, etc., with black manganese oxide and hydrochloric acid, whereby the chlorine acts *in statu nascendi*. The following details of the manufacture of chloral hydrate as carried out on a commercial scale have been supplied by E. Schering, of Berlin, who has been for some years the largest manufacturer of it. Absolute alcohol in lots of 50 pounds is placed in large glass flasks and saturated with chlorine, which is passed in a continuous stream for 6 to 8 weeks. The chlorine is led into cold alcohol at first, and when no more is absorbed, the alcohol is heated at first gently and then to 60° C. (140° F.). When saturated, the mixture formed is agitated with sulphuric acid at a temperature of 60° C. (140° F.) for several hours, during which time most of the hydrochloric acid escapes. The separated chloral is then rectified over calcium carbonate. The pure chloral so obtained is then mixed in glass flasks with the necessary amount of water, and the resulting hydrate either cast into cakes or purified by crystallization. As solvents for this purpose certain of the side products of the chloral manufacture, after being purified and rectified, are used, for instance, ethylene and ethylidene chlorides. Or in their absence chloroform is used; petroleum benzin and carbon disulphide have also been recommended. The action of chlorine upon alcohol is said to be aided by the presence of "chlorine carriers," such as iodine, ferric chloride, thallium chloride, etc. The formula of anhydrous chloral is C_2Cl_3HO; in other words, aldehyde, C_2H_4O, in which 3 atoms of hydrogen have been replaced by 3 atoms of chlorine. The alcohol, C_2H_6O, may be supposed to give up 2 atoms of its hydrogen to form aldehyde, which exchanges 3 of its atoms of hydrogen for 3 atoms of the chlorine, the hydrogen forming hydrochloric acid with 3 other atoms of the chlorine. The name of chloral was derived from the *chlor*ine and *al*cohol from which it is formed. The anhydrous chloral thus formed is a colorless liquid, of penetrating disagreeable odor, of little taste, of the sp. gr. 1·502, and boiling at 94° C. (201·2° F.). It is soluble in ether or chloroform without change. According to A. Trillat, in the formation of chloral from alcohol, the latter is first changed by the action of the chlorine into aldehyde; this unites with alcohol to form acetal, which is changed successively into mono-, di-, and trichloracetal; the action of hydrochloric acid decomposes this latter with the formation of chloral alcoholate and ethyl chloride; sulphuric acid decomposes the alcoholate, liberating chloral, which then is made to combine with water to form the crystalline chloral hydrate. (*Bulletin*, 1897, 17, 230.)

Meta-chloral. By continued contact of anhydrous chloral and concentrated sulphuric acid, a change is effected in the chloral, by which it becomes a solid insoluble in water, which is designated as *insoluble chloral*, or *meta-chloral*. It is tasteless, of a white color resembling porcelain, and insoluble in alcohol and ether. Its formula is $C_6H_3Cl_9O_3$, being formed by the union of three molecules of chloral. It is stated that when perfectly pure, chloral does not become polymerised; the change is also said to be prevented by the addition of a little chloroform. When heated to 180° C., metachloral distils with reversion to liquid chloral. (Allen, *Com. Org. Analysis*, 2d ed., i. p. 171.)

Chloral Alcoholate. A compound obtained by M. Roussin, which he announced as pure chloral hydrate, was found by M. Personne to contain no water, but to be in fact a compound of alcohol and chloral, and is now known by the name of *chloral alcoholate*, C_2HCl_3O,C_2H_6O. It results directly from the action of absolute alcohol on anhydrous chloral, and is now known to be formed as a stage in the manufacture of chloral from alcohol. As it is very likely to be confounded with chloral hydrate, the following points of difference should be noted. It forms white crystals melting at 46° C. (114·8° F.), and boils at 113·5° C. (236° F.), while chloral hydrate crystals melt at 58° C. (136·4° F.), and boil at 97·5° C. (207° F.); chloral alcoholate melts without complete solution when warmed with two volumes of water, and, on cooling, congeals below the surface of the water, while chloral hydrate is soluble in one and one-half times its weight of water; chloral alcoholate, gently heated with nitric acid of 1·2 sp. gr., is

violently attacked, while chloral hydrate is scarcely acted on; chloral alcoholate, heated on platinum foil, inflames readily, while chloral hydrate scarcely burns. (Allen, *Com. Org. Analysis*, 2d ed., i. p. 172.)

The three related products, the *anhydrous chloral*, the polymeric *meta-chloral*, and the *alcoholate*, described above, have been more or less introduced into the European markets, and have required some notice to prevent them from being confounded with the hydrate, which is alone official. The following observations will be confined to this compound; and the reader will note that whether the simple term chloral, or the exact designation, chloral hydrate, is used, the same substance is intended.

Properties of Chloral Hydrate, or Chloral, *U. S.* This results from simply mixing anhydrous chloral with water. Acicular crystals soon form, which consist of a molecule each of the chloral and water, constituting chloral hydrate, or official chloral. As employed in the United States, this comes, we believe, exclusively from Europe, and chiefly from Germany. It was at one time made in this country by Dr. E. R. Squibb, of Brooklyn. It occurs in commerce mainly in two forms, in distinct crystals, which is the official form, or in crystalline plates,* about three lines in thickness, broken into small, irregular, angular pieces, so as to be readily introduced into broad-mouthed bottles. These pieces, while retaining their tabular form, are somewhat translucent, but usually covered with a white powder, which somewhat conceals that property. This is the more common form and the cheaper; but the crystals are to be preferred, as their purity may be relied on. Chloral is white, of a peculiar pungent odor, and an acrid pungent taste, especially affecting the velum pendulum. The odor has been compared to that of an over-ripe melon. Exposed to the air it very slowly volatilizes, and, like camphor, when enclosed in a bottle, covers the interior surface with numerous minute crystallizations. The boiling point of the pure crystals is 97·5° C. (207° F.). If the boiling point be under 95° C., it indicates an under-hydrated preparation; if above 98° C., an over-hydrated one. (E. R. Squibb.) The pure hydrate does not take fire when heated in a spoon, but evaporates without residue. With the aid of heat, its solution may be effected readily in chloroform; and the solution, on cooling, deposits it in beautiful crystals, which are generally needle-shaped; but, when deposited from carbon disulphide, they are prisms. The aqueous solution is prone to decomposition, which is ultimately attended with the development of low organisms. Chloral should not, therefore, be kept long in this state. (Dr. E. Labbée, *Arch. Gén.*, Sept. 1870.) In its relation to acids and alkalies it is neutral, or, according to E. Schering, slightly acid when perfectly pure. When equal parts of chloral in crystals and of camphor in small fragments are shaken together in a bottle, and allowed to stand, they liquefy, forming a clear solution. When chloral and sulphuric acid are mixed, the temperature is greatly reduced. A solution of chloral hydrate dissolves morphine, quinine, and most of the vegetable alkaloids. (R. F. Fairthorne, *A. J. P.*, Oct. 1871, p. 447.) When ammonium sulphide is added to an aqueous solution of chloral hydrate, the mixture rapidly turns yellow, and, after passing through several shades of color, finally becomes dark brown. From this liquid diluted sulphuric acid throws down a bulky brown precipitate. This, purified from precipitated sulphur and dried, is a light-brown powder of the composition $C_{18}H_{24}S_{13}N_4O_6$. Hydrogen sulphide gas forms a sulphydrate by its action on chloral. These reactions are important, as the detection of metallic poisons in toxicological cases by hydrogen sulphide has been complicated by the presence of chloral hydrate. A still more important chemical reaction of chloral is that which takes place when the hydrate, or either of its other forms, is placed under the influence of an alkali. Chloroform is developed, and along with it a formate of the alkali employed. Thus, in a strong solution of potassa, put a pinch of powdered chloral, and almost instantly the odor of chloroform becomes sensible, and some oil-like globules of chloroform may be seen at the bottom of the vessel. The reaction is as follows:

$$\underset{\text{Chloral hydrate}}{C_2HCl_3O,H_2O} + \underset{\text{potassium hydrate}}{KOH} = \underset{\text{chloroform}}{CHCl_3} + \underset{\text{potassium formate}}{CHO.OK} + \underset{\text{water}}{H_2O.}$$

This relation of chloral to chloroform would serve as a ready test of the former, and may be used also to determine its quality; for pure chloral hydrate ought by calculation to yield 76·35 per cent. of chloroform, and the best known yields, according to the table of Mason, 71·5 (72·20 Selden) per cent. If, therefore, the product of chloroform should fall much below the

* M. Guérin adds his testimony to the necessity for dispensing only chloral hydrate which has been recrystallized and which is in the form of distinct crystals. He examined many samples, and found acidity in the cake variety, due, as he believes, to the formation of hydrochloric and formic acids, produced by the action of water retained in the cake during the manufacture, and this remaining in contact with the confused mass of crystals excites decomposition. (*Archiv d. Pharm.*, 1886, p. 253.)

latter percentage, the parcel acted on is probably impure. For other methods of assaying chloral hydrate, see Allen, *Com. Org. Analysis*, i. pp. 174 and 175. The following tests of purity are given in the U. S. Pharmacopœia. "Separate, rhomboidal, colorless and transparent crystals, having an aromatic, penetrating, and slightly acrid odor, and a bitterish, caustic taste; slowly volatilized when exposed to the air. Freely soluble in water, alcohol, or ether; also in chloroform, benzol, benzin, carbon disulphide, fixed and volatile oils. It liquefies when triturated with about an equal quantity of camphor, menthol, thymol, or carbolic acid. When heated to about 58° C. (136·4° F.), it melts, forming a liquid having a specific gravity of about 1·575, which, at a higher temperature, should not evolve inflammable vapors. Liquefied Chloral solidifies to a crystalline mass between 35° and 50° C. (95° and 122° F.). Chloral is decomposed by caustic alkalies, alkaline earths, and ammonia, chloroform being formed, and a formate of the base produced. A freshly prepared, aqueous solution of Chloral is neutral, but gradually acquires an acid reaction. A neutral alcoholic solution remains neutral permanently. Chloral should be dry, and not readily attract moisture in dry air. A solution of Chloral (1 in 20) in diluted alcohol, acidulated with nitric acid, should remain unaffected by silver nitrate test-solution (absence of *hydrochloric acid* and *chlorides*). If 1 Gm. of Chloral be dissolved in 2 C.c. of warm water, mixed with potassium hydrate test-solution in slight excess (about 8 C.c.), the mixture filtered, and a portion of the clear filtrate treated with iodine test-solution until it is yellowish, no yellow, crystalline precipitate (iodoform) should appear within half an hour (absence of *chloral alcoholate*)." "Soluble in less than its own weight of *water*, *alcohol* (90 per cent.), or *ether*, and in four times its weight of *chloroform*. The aqueous solution is neutral or but slightly acid to *litmus*. On the application of heat Chloral Hydrate fuses to a colorless liquid, which, as it cools, begins to solidify at a temperature of about 120° F. (48·9° C.). In a test-tube it boils, when pieces of broken glass are immersed in it, at from 202° to 206° F. (94·4° to 96·7° C.), and on platinum foil at a slightly higher temperature it volatilizes without residue. In presence of alkaline substances Chloral Hydrate is decomposed and chloroform is liberated. If 4 grammes be heated with 30 cubic centimetres of the *volumetric solution of sodium hydroxide*, no more than 6 cubic centimetres of the *volumetric solution of sulphuric acid* should be required to neutralize the soda which remains free on the completion of the reaction. A solution in *chloroform*, when mixed by agitation with *sulphuric acid*, does not impart color to the acid (absence of certain organic impurities). When 1 gramme of Chloral Hydrate is warmed with 6 cubic centimetres of *water*, and 0·5 cubic centimetre of *solution of potassium hydroxide*, the mixture filtered, sufficient *solution of iodine* added to impart a deep-brown color, and the whole set aside for an hour, a yellow crystalline precipitate of iodoform should not result (absence of chloral alcoholate). Its aqueous solution should not afford any precipitate with *solution of silver nitrate* (absence of free chlorides)." *Br.*

The most delicate test for the presence of chloral alcoholate in chloral hydrate is said to be that with nitric acid. When 1 C.c. of nitric acid (1·38 sp. gr.) is poured over 1 Gm. of chloral hydrate a yellow color should not appear within 10 minutes, even if the mixture be warmed. (*A. J. P.*, 1894, 191.) For other tests for chloral hydrate by Jaworowski, see *Pharm. Zeit. f. Russl.*, 1894, 373.

Medical Properties and Uses. When chloral is ingested in full therapeutic dose (from 15 to 30 grains), it produces in from ten minutes to half an hour a quiet, placid sleep, which usually continues about three hours, when it ceases, generally without any unpleasant symptom during its progress or after its termination. In some instances the ordinary doses fail to cause sleep, and in others the sleep is attended with dreams and hallucinations, and followed by unpleasant symptoms, like those which often succeed other hypnotics, especially opium; such as nausea, headache, unpleasant nervous disorder, etc. These diversities may be ascribed in part to peculiarity of constitution; but more frequently, in all probability, they are owing to morbid conditions existing at the time, which oppose themselves to the proper action of the chloral. In an individual in health chloral will probably almost always induce a calm sleep, differing little from the natural. Moreover, these unpleasant symptoms are now much more rarely produced than formerly, and there can be but little doubt that they have often been due to the impurities of the drug. The pulse is in this degree of action not affected, or is rendered a little slower; the pupil is contracted, but becomes normal so soon as the subject is awakened; the respiration is deep, full, and regular. When larger amounts are given, the sleep is much deeper, and may pass into profound coma; the respirations fall in number; the pulse is weakened and rendered slower, but may become rapid and irregular if the dose has been toxic; the temperature is reduced; the muscular system is relaxed, and both sensibility

and reflex action are diminished. If a fatal dose has been given, all these symptoms are intensified: with coma, intense muscular relaxation, weak, thready pulse, and a pupil contracted at first, but afterwards dilated, the victim gradually sinks into death, paralyzed and anæsthetic. The immediate cause of death is generally a paralytic arrest of respiration; but in many cases there appears to have been a simultaneous arrest of the cardiac action, and it is very possible that fatal syncope may at times occur. At post-mortem examination, congestion of the meninges and substance of the brain and cord, and of the lungs, is commonly found. The blood is thought by Richardson (*Med. Times and Gaz.*, Sept. 4, 1870) to coagulate less firmly than normal.

After the brain the motor tract of the spinal cord, including the respiratory centre, is most sensitive to the action of chloral. The loss of voluntary muscular power and the lessening of reflex activity which the drug produces are the result of this spinal influence. Upon the sensory tract of the cord chloral acts with much less vigor, while the nerves and muscles practically escape its influence. Of course any agent which produces sleep in some measure relieves pain, but the anæsthetic influence of chloral is far from pronounced, and often patients on waking will complain bitterly of pain suffered during sleep.

The physiological action of chloral may be summed up as follows. Upon the cerebrum it acts as a most powerful and certain hypnotic; in full doses it acts as an intense depressant upon the centres at the base of the brain, and upon the spinal cord, causing slowing and weakness of the heart's action, probably vaso-motor paralysis, slowing of the respiration, and muscular weakness, lessening of reflex activity, with a certain amount of anæsthesia; in fatal doses it causes death generally by arresting respiration through paralysis of the nerve-centres, and finally stopping the heart in diastole. Its action in very small doses is uncertain, but there is considerable evidence to indicate that it irritates or stimulates the spinal and the cardiac, and even the vaso-motor, centres. On the vagi and on the motor nerve-trunks it has no marked influence. Clinical experience indicates that chloral acts as a depressant to the heart-muscle; although some authorities believe the influence of the drug upon the heart is not direct, but exerted through the nerve-centres. Chloral has little effect on the secretions, though it is said somewhat to increase the secretion of urine. In man, it is stated by Bouchut that, in accordance with his observations, this secretion is not only increased, but has been found also augmented in density; at the same time reducing the cupro-potassic liquor, and rendered brown by potassa or bismuth subnitrate; as if a temporary glycosuria were produced. Formic acid has never been found in the urine as a result of the taking of chloral. (*Arch. Gén.*, Sept. 1870, p. 346.)

The conversion of chloral by alkalies in solution into chloroform and formic acid first suggested its use in medicine to Liebreich (*Wiener Medicinische Wochenschrift*, August, 1869); and the theory that its action is really due to chloroform generated by the alkalinity of the blood has been received with favor by Personne and other writers, but there are very many facts which militate against the truth of this supposition. Thus, chloroform cannot be detected in either the blood, breath, or excretions of chloralized animals, although chloroform at once manifests itself when it is administered, and in the so-called "salt frogs" of Cohnheim, after substitution of warm salt water for the blood of the animal, chloral acts as upon the normal batrachian.

Chloral, especially when used continuously, is said to produce in some individuals serious disturbances. Such are vaso-motor paralysis, transient skin neurosis, acute purpura, and great prostration of the heart's action, sometimes amounting to paralysis of that organ, and sometimes ending fatally, even though the doses of the chloral used were within the limits ordinarily deemed safe. For a full discussion of these phenomena, see H. C. Wood's *Therapeutics*. There can be no doubt that great caution should be practised in administering the drug when the heart is very weak or the general powers are much enfeebled. Dr. Jolly relates two cases in which 5 grammes (about 76 grains), given every night, caused death, in one case after the fifth dose, and in the second after the thirteenth dose, without abnormal symptoms until after the last dose, when the action of the heart and respiration suddenly ceased, and the patient died. (*N. Y. Med. Journ.*, Nov. 1872.) These cases would appear to justify the statement that there is a possible cumulative action of the drug. Although 480 grains have been recovered from, Dr. Fuller has recorded a case in which a single dose of thirty grains proved fatal in a young lady, and two others in which the same quantity caused alarming symptoms in similar circumstances: so that the highest dose to begin with in ordinary diseases, especially in delicate women, should not exceed twenty grains. In poisoning by chloral, if the case be seen early, the stomach should be thoroughly evacuated by an emetic or the stomach-pump, and the

system afterwards supported by cardiac and respiratory stimulants, as milk punch, ammonium carbonate, etc. Atropine, digitalis, and strychnine should be administered freely, and the same general measures taken to sustain the respiration as are usually practised in opium poisoning. Atropine is undoubtedly of value when there is failure of respiration, and care should always be taken to maintain the bodily temperature. Artificial respiration should be practised when necessary. The bodily temperature should be maintained by external heat.

From what has been said it will be readily perceived that the two great indications for this remedy are to procure sleep and to relax spasm. In pure *nervous insomnia*, and in the same affection attendant on various diseases, as in *acute fevers*, *active congestion of the brain*, *cerebral inflammation*, *mania*, *delirium tremens*, etc., it is superior to opium; fifteen to twenty or twenty-five grains (1–1·3 or 1·565 Gm.) are generally sufficient for a commencing dose, to be repeated in half the quantity in an hour if the first dose fail. The sleep is usually calm and undisturbed for three or four hours, and may be renewed, if required, by the repetition of the dose. When the sleeplessness is due to pain, opium is much more effective than chloral. The combination of chloral and morphine is often very useful in procuring sleep for the suffering. As an anæsthetic, chloral should never be employed; the intravenous use of it, as at one time practised in France, is most dangerous and absolutely unjustifiable. In spasmodic affections chloral is one of the most powerful remedies known. In *tetanus* and in *strychnine poisoning* it is singularly useful, but must be given in very large doses. In *hysteria*, *severe chorea*, and other functional or spinal convulsions, it is no less efficient. In *epilepsy* and other forms of cerebral convulsions chloral is of less service, although it is frequently employed with benefit in puerperal convulsions. In *local spasms* it is often of service, and it has been used with success in *strangulated hernia*, *spasm of the glottis*, *spasmodic croup*, *asthma*, *hiccough*, and even in *incontinence of urine*. Chloral is possessed of very decided antiseptic properties; a solution of the strength of 30 grains to the ounce will preserve animal tissues for a long time. Locally applied, chloral is stimulating and antiseptic, and may occasionally be used with very good results in the treatment of *foul sores*, *irritable ulcers*, etc., which need stimulation. The solution may vary from five to thirty-one grains to the ounce, according to the exigencies of the case. Dr. A. M. Fauntleroy states that if powdered chloral be sprinkled on adhesive plaster and the whole heated sufficiently to adhere to the skin, and applied whilst warm, there is produced an increasing burning, and in about ten minutes a blister is formed.

Pharmaceutical Preparations. Chloral is best administered in solution with syrup of orange flowers, or in simple solution. The French sometimes employ *chloral cream*, made of chloral hydrate 5 parts, water 15 parts, white sugar finely powdered 100 parts, flavored with mint, orange, or vanilla. One grain of chloral is contained in 24 grains of the cream, and a teaspoonful is equivalent to about 3 grains of chloral. This preparation keeps well, and the dose may be dissolved in a little water. *Chloral liniment* may be made by dissolving 6 parts chloral in 30 parts oil of sweet almonds. *Chloral ointment*, 6 parts chloral, 3 parts white wax, 27 parts lard; the lard and wax are melted at a gentle heat, the chloral added in powder and dissolved. (See *Chloral Camphoratum*, PART II.) *Chloral plaster*, to produce counter-irritant effects, is prepared by spreading powdered chloral on Burgundy pitch plaster.

CHLOROFORMUM. U. S., Br. Chloroform.

$CHCl_3$; 119·08. (KHLŌ-RO-FÖR'MŬM.) $CHCl_3$; 119·2.

"A liquid consisting of 99 to 99·4 per cent., by weight, of absolute Chloroform, and 1 to 0·6 per cent. of Alcohol. It should be kept in dark amber-colored, glass-stoppered bottles, in a cool and dark place." *U. S.* "Chloroform, or trichloromethane, $CHCl_3$, to which has been added sufficient Absolute Alcohol to produce a liquid having a specific gravity not less than 1·490, and not more than 1.495. Trichloromethane may be prepared by heating a mixture of chlorinated lime, slaked lime, ethylic alcohol, and distilled water." *Br.*

Chloroformum Purificatum, *U. S.* 1880; Chloroformium, *P. G.;* Formylum Trichloratum; Chloroforme pur, *Fr.;* Reines Chloroform, *G.*

Neither the U. S. nor British Pharmacopœias give detailed processes for chloroform. (See *U. S. D.*, 17th ed., 370.)

In the U. S. Pharmacopœia of 1850 a process was given for preparing chloroform; but, as this is never made on a small scale by the apothecary, it was very properly transferred, in 1860, to the Materia Medica Catalogue. *Chloroformum venale*, or commercial chloroform, was introduced, and also a formula for the purification of chloroform; this was very properly dropped in the U. S. P. 1890, as pure chloroform is now furnished by the manufacturers and easily obtainable at a

moderate price; the process for purifying chloroform attached to the tests of the U. S. P. (1880) will be found below. The process of the British Pharmacopœia (1885) is for the preparation of the chloroform *ab initio*, with directions which secure its purity if complied with. In this process, the reaction by which the chloroform is produced takes place between the chlorinated lime and the alcohol; the slaked lime being intended probably to lessen the production of the chlorinated pyrogenous oil. As first distilled, the chloroform is very impure, and is directed to be washed first with ordinary water, and afterwards with distilled water, which separate alcohol, chlorine, and probably other contaminating substances. In consequence of the density of the chloroform and its insolubility in water, it readily subsides, forming a distinct layer which may be easily separated. The crude product, after having been freed from alcohol by the washing with water, is purified from the chlorinated pyrogenous oil, which comes over with the chloroform, by agitation with an equal volume of sulphuric acid, which ought to be *pure* and *colorless*, and at least of the density 1·840. The oil is charred and destroyed by the acid, which becomes yellow or reddish brown, and is partially changed into sulphurous acid. To remove the latter acid, as well as any water present, the chloroform, which floats on the surface of the acid, is removed and agitated well with chloride of calcium and quick lime, then again submitted to distillation, and one per cent. of absolute alcohol added to preserve the chloroform from decomposition. In the U. S. 1880 process (see 16th edition U. S. D.) the method of purification is somewhat different. Instead of equal measures of the impure chloroform and sulphuric acid and an agitation for only 5 minutes, the commercial chloroform is shaken occasionally for 24 hours with but one-fifth of its weight of the acid. To remove any water and acid that may be present, instead of calcium chloride and lime, a little stronger alcohol is mixed with the chloroform in a dry retort, and then lime in coarse powder is added, and the mixture is distilled to dryness.

Purification, *U. S. P.* 1890. Chloroform which fails to respond to these tests (see p. 380) should be purified by the following process. Chloroform, *four hundred grammes* [or 14 ounces av., 48 grains]; Sulphuric Acid, *eighty grammes* [or 2 ounces av., 359 grains]; Dried Sodium Carbonate, *twenty grammes* [or 308 grains]; Deodorized Alcohol, *four cubic centimeters* [or 65 minims]. Add the Sulphuric Acid to the Chloroform, contained in a glass-stoppered bottle, and shake them together occasionally during twenty-four hours, avoiding exposure to bright daylight. Separate the lighter Chloroform layer, add to it the Dried Sodium Carbonate, previously rendered anhydrous by heating it in a porcelain capsule on a sand-bath until it ceases to give off aqueous vapor, and shake them together frequently and thoroughly during half an hour. Then transfer the Chloroform to a dry retort, add to it the Alcohol, and distil, by means of a water-bath, at a temperature not exceeding 67·2° C. (153° F.), into a well-cooled receiver, until the distillate measures *two hundred and fifty-five cubic centimeters* [or 8 fluidounces, 298 minims].

It sometimes happens that the chloroform purified with sulphuric acid, though apparently pure at first, will not keep, but after some time becomes so loaded with chlorine and hydrochloric acid as to be altogether unfit for respiration. Dr. Squibb attributes the fact that chloroform purified by concentrated sulphuric acid does not keep well, to the very purity attained. He believes that perfectly pure chloroform is prone to decomposition, and is rendered more stable by the addition of a small proportion of alcohol, so as to reduce its density to the official standard. This he effects by adding alcohol in the proportion of ten drops to each fluidounce of good chloroform of maximum density (see *Amer. Med. Monthly*, July, 1857). This recommendation was carried into effect in the U. S. 1880 process, and explains the addition of alcohol before distillation. Dr. Gregory also attributes the tendency to decomposition to its purity, and to the action of sunlight; having found that those portions which he had purified with the greatest care were soonest decomposed under the influence of light. For methods of preserving chloroform by the use of sulphur, hypophosphorous acid, etc., see *P. J. Tr.*, 1895, 261; also 1896, 249.

As chloroform of great purity is *usually* to be purchased in the market, it is not necessary for the pharmacist to apply the official process of purification to every parcel that he may meet; but it is in the highest degree incumbent on him to sell none for inhalation which is not so pure as to stand the tests given in the Pharmacopœia, and if he can obtain none so pure, then to purify it himself.

The intermediate formation of chloral as a result of the reaction between alcohol and chlorinated lime suggested the preparation of chloroform from chloral, which has of late years been produced in immense quantities. The advantages which were anticipated from decom-

posing pure chloral hydrate with alkalies have not altogether been realized, for the product is much more expensive, and the claim of greater stability has not been sustained, as it requires just as much alcohol to preserve it as that made in the usual way.

Chloroform is now made on a large scale both in this country and in Germany by the distillation of acetone with chlorinated lime; indeed, this process has latterly almost entirely replaced the manufacture from alcohol. Liebig, as long ago as 1832, described the reaction, but it was thought to be not adapted for commercial use. In 1882 the manufacture was begun on a commercial scale at Mannheim, Germany, and since June, 1885, in this country. To get a satisfactory yield a very pure acetone is necessary. When such acetone is taken, a yield of nearly or quite 200 per cent. of chloroform can be obtained. (For an account of the methods of purifying the acetone and distilling with chlorinated lime, see *A. J. P.*, 1889, p. 321.) In July, 1885, a patent was taken out by G. Michaelis, of Albany, for the manufacture of chloroform from the liquid products resulting from the decomposition of crude acetates at high temperatures. These liquid products are acetone and other higher ketones. The purified chloroform from acetone has a small quantity of alcohol added to prevent decomposition and bring it to Pharmacopœia requirements. Pure methyl alcohol, on the other hand, does not yield chloroform. The erroneous statements on this point generally current are probably due to the fact that commercial wood spirit contains a large percentage of acetone.

Dr. Squibb prefers acetic acid to the acetates in the intermediate step of making acetone, thus avoiding impurities apt to be present in acetates; he believes that the grant of a patent for "acetone chloroform" was deficient in equity. (*Ephemeris*, 1896, 1743–1757.)

Still another method for the manufacture of chloroform from acetone is described in the French technical journals,—viz., to electrolyze a solution of common salt mixed with acetone. A retort of enamel-lined iron, jacketed at the bottom so as to be heated by steam, and provided with a delivery and condensing tube, is used. A 20 per cent. solution of common salt is introduced into the retort and heated to boiling, when the current is made to pass and a continuous stream of acetone is run in. The nascent chlorine liberated rapidly converts the acetone into chloroform, and it distils over. It is claimed that "190" per cent. of the weight of the acetone taken is obtained as chloroform. Lead electrodes were used at first, but these have been replaced by carbon rods which can be attached to a vertical shaft and made to serve as stirrers. The negative electrode consists of a copper cylinder. (*Revue Scientifique*, Feb. 1893.)

Carbon tetrachloride (CCl_4) has also been proposed (1896) as a source of chloroform, and as it is now made cheaply on a large scale, it may come into use. By the action of hydrochloric acid and zinc, hydrogen is liberated and attacks the carbon tetrachloride, forming chloroform and hydrochloric acid, $CCl_4 + H_2 = CHCl_3 + HCl$. As hydrochloric acid is a product of the reaction, fresh quantities of zinc are attacked, and a new liberation of chloroform follows.

Discovery and History. Chloroform was discovered by Mr. Samuel Guthrie, of Sackett's Harbor, N.Y., in 1831, and about the same time by Soubeiran in France, and Liebig in Germany. Guthrie obtained it by distilling a gallon from a mixture of three pounds of chlorinated lime and two gallons of alcohol of the sp. gr. 0·844, and rectifying the product by redistillation, first from a great excess of chlorinated lime, and afterwards from potassium carbonate. (*Silliman's Journal*, vol. xxi., Jan. 1832, p. 64.) In a subsequent letter to Professor Silliman, dated Feb. 15, 1832, Mr. Guthrie states that the substance which he had obtained, "distilled off sulphuric acid, has the specific gravity of 1·486, or a little greater, and may then be regarded as free from alcohol; and if a little sulphuric acid which sometimes contaminates it be removed by washing it with a strong solution of potassium carbonate, it may then be regarded as *absolutely pure*." (*Ibid.*, vol. xxii., July, 1832, p. 105.) It is thus evident that Mr. Guthrie obtained, in a pure state, the substance now called chloroform; but he erroneously supposed his product to be the well-known oily liquid of the Dutch chemists, which it greatly resembles, and for the preparation of which he believed he had fallen on a cheap and easy process. Under this impression, he called the substance, in his communications, *chloric ether*, one of the names by which *Dutch liquid*, or *ethene dichloride*, is designated. He was induced to make the preparation from noticing in Professor Silliman's *Elements of Chemistry* a reference to the Dutch liquid as a grateful diffusible stimulant when properly diluted with alcohol and water. (See also *West. Drug.*, 1894, 51.)

Properties. Chloroform is "a heavy, clear, colorless, mobile, and diffusible liquid, of a characteristic, ethereal odor, and a burning, sweet taste. Specific gravity, not below 1·490 at 15° C. (59° F.), or 1·473 at 25° C. (77° F.). Chloroform is volatile even at a low temperature, and boils at from 60° to 61° C. (140° to 141·8° F.). It is not inflammable, but its heated

vapor burns with a green flame." *U. S.* "A liquid of characteristic odor and pungent sweet taste. Specific gravity 1·490 to 1·495. It should boil between 140° and 143·6° F. (60° and 62° C.)." *Br.* According to Remys (*Archiv der Pharm.*, 3, v. 31), pure chloroform has the sp. gr. of 1·500 at 15° C. (59° F.). Besnou gives the densities of various mixtures of alcohol and the purest commercial chloroform at 4·5° C. (40° F.) as follows:

Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.	Specific Gravity.	Chloroform, per cent.	Alcohol, per cent.
1·4945	100·0	0·0	1·4772	97·5	2·5
1·4908	99·5	0·5	1·4602	95·0	5·0
1·4874	99·0	1·0	1·4262	90·0	10·0
1·4845	98·5	1·5	1·4090	87·5	12·5

When pure, it has no action on potassium, except to cover the surface of the metal with small bubbles of gas. Chloroform is a powerful antiseptic. Like creosote, it does not coagulate albumen. It is scarcely acted on by sulphuric acid in the cold, but dissolves readily in alcohol and ether. The alcoholic solution, when moderately diluted with water, forms an aromatic, saccharine liquid of a very grateful taste. A strong alcoholic solution is decomposed by abundance of water, the chloroform separating and subsiding, and the alcohol uniting with the water. "Soluble in about 200 times its volume of cold water, and, in all proportions, in alcohol, ether, benzol, benzin, and the fixed and volatile oils." *U. S.* It is liable to decomposition by sunlight, or even diffused daylight; and hence the propriety of keeping it in bottles, covered with dark paper, in a rather dark place. Chloroform has extensive solvent powers, being capable of dissolving caoutchouc, gutta-percha, mastic, elemi, tolu, benzoin, and copal. Amber, sandarac, lac, and wax are only partially soluble. It also dissolves iodine, bromine, the organic alkalies, the fixed and volatile oils, most resins, and fats. It dissolves sulphur and phosphorus sparingly. It possesses the power of dissolving a large quantity of camphor, and furnishes the means of administering that medicine in an elegant form. As a general solvent, it has the advantage over ether of not being inflammable; the inflammability of the latter being the cause of frequent accidents. For an extensive list of substances soluble, insoluble, and partly soluble in chloroform, see a paper by M. Lepage, of Gisors, France, copied into *A. J. P.*, 1852, p. 147. It has been found by J. B. Barnes that chloroform has the power of preventing the alcoholic, lactic, and other fermentations, probably by killing the organisms that provoke these processes. Twenty minims preserved sixteen ounces of malt, to which two drachms of yeast had been added, as long as the experiment lasted. The same quantity kept fresh eight fluidounces of milk in a warm place for five days. Mucilage and infusions were preserved for weeks with one minim or even less to the ounce. Similar results were reached by Mr. F. J. Barrett and others. (*P. J. Tr.*, 1874, pp. 441, 442, 455.) The active properties of chloroform forbid its use as a preservative of medicinal infusions, but from milk it could always be removed by boiling. A. Munz (*P. J. Tr.*, 1875, p. 967) proposes the employment of chloroform as a test between chemical and living ferments, since he has found it to have no effect upon the former, though absolutely destructive to the latter.

Composition. Chloroform is composed of one atom of carbon, one of hydrogen, and three of chlorine. Its simplest derivation in theory is from marsh-gas (*methane*), CH_4, whence it is often called *trichloro-methane*. While it can be thus produced, by the action of chlorine upon marsh-gas, in practice, it is formed either from alcohol by the action of bleaching-powder, from chloral by an alkaline hydrate, or latterly from acetone and bleaching-powder.

The reactions are sometimes complex, but if the temperature be carefully kept at from 70° C. (158° F.) to 73° C. (163·4° F.), they are essentially as follows:

$$C_2H_6O + CaOCl_2 = CaCl_2 + C_2H_4O + H_2O;$$

that is, one molecule of bleaching-powder, reacting with one of alcohol, yields one of calcium chloride, one of aldehyde, and one of water. The aldehyde formed is then further decomposed, according to the reaction

$$2(C_2H_4O) + 6(CaOCl_2) = 3CaCl_2 + 3Ca(OH)_2 + 2(C_2HCl_3O);$$

that is, two molecules of aldehyde, reacting with six of bleaching-powder, yield three of calcium chloride, three of calcium hydrate, and two of chloral. The chloral is, however, decomposed by the free base calcium hydrate, according to the reaction

$$2(C_2HCl_3O) + Ca(OH)_2 = Ca(CHO_2)_2 + 2(CHCl_3);$$

that is, two molecules of chloral reacting with one of calcium hydrate yield one of calcium formate and two of chloroform. The reaction for the manufacture from acetone is simpler:

$$2C_3H_6O + 6CaOCl_2 = 2CHCl_3 + 2Ca(OH)_2 + Ca(C_2H_3O_2)_2 + 3CaCl_2.$$

Impurities and Tests. Chloroform is liable to contain alcohol and ether, both of which lower its specific gravity. If it have a less density than 1·38, it will float instead of sinking in a mixture of equal weights of concentrated sulphuric acid and water after it has cooled. M. Mialhe has proposed the following test for the presence of alcohol. Drop into distilled water a small quantity of the chloroform. If pure, it will remain transparent at the bottom of the glass; but if it contain even a small proportion of alcohol, the globules will acquire a milky appearance. Soubeiran's method was to agitate almond oil and chloroform together in a tube. If the chloroform be pure, it remains clear; if it contain as much as 5 or 6 per cent. of alcohol, it becomes milky. (*Journ. de Pharm.*, Août, 1860, p. 95.) Prof. Procter detected alcohol by adding the suspected chloroform to an oxidizing mixture of potassium bichromate and sulphuric acid. If alcohol be present, the deep orange color of the chromic mixture will gradually become green; if absent, no change of color will take place. (*A. J. P.*, 1856, p. 213.) Hoffmann's violet has been recently suggested as a test. If a small portion is added to chloroform containing alcohol, the solution is colored a deep purple. Boettger recommends adding to the chloroform a solution of molybdic acid in pure, strong sulphuric acid, when even a trace of alcohol will cause an intense blue color. (1879.) Chloroform, when pure, upon being mixed with an equal volume of sulphuric acid, does not color it; but when contaminated with these oils it gives the acid a color varying from yellow to reddish brown, according to the amount of impurity. Alcohol also is detected and removed by sulphuric acid. In applying this test, several fluidounces of chloroform should be used, as a slight change of color cannot be easily seen in a test-tube, and care must be taken to see that mechanical impurities, like cork-dust, dirt, etc., have been filtered out of the specimen, or the acid will be discolored from this cause. A still more delicate test of the oily impurities, according to Dr. Gregory, is the smell which they leave. If chloroform thus contaminated be poured upon the hand, it quickly evaporates, leaving the oily impurities, recognizable by their offensive odor, now no longer covered by that of the chloroform. The pure substance, rubbed on the skin, quickly evaporates, and leaves scarcely any smell. Chloroform sometimes contains Dutch liquid, which may be discovered by adding an alcoholic solution of potassa; when the mixture, if this impurity be present, will heat and give off a permanent gas, which is *acetyl chloride*, C_2H_3OCl. (Geuther.)* Fuming nitric acid, heated with chloroform to 100° C. (212° F.) in a closed tube for 120 hours, forms a new substance, *chloropicrine*.

Two methods for purifying chloroform, one physical and the other chemical, have been brought out in the last year or so and have attracted much attention. The first of these is the Pictet method of purifying the chloroform by submitting it to very low temperatures, whereby the impurities are first frozen out and filtered off from the chloroform at —70° C., and then the chloroform itself is solidified at from —80° C. to —100° C. and separated from any liquid impurities. It was at first claimed for this "Chloroform Pictet" that it would not be decomposed by sunlight and did not require the addition of alcohol to preserve it. These claims do not seem to be substantiated by later tests. The other method is based on the discovery of R. Anschütz, that chloroform crystallizes out with salicylid, $C_6H_4\left\{\begin{matrix}CO\\O\end{matrix}\right>$, and *o*-homosalicylid, $C_6H_3(CH_3)\left\{\begin{matrix}CO\\O\end{matrix}\right>$, while the impurities of chloroform remain. These crystalline compounds contain respectively 33·24 and 30·80 per cent. of chloroform, and this can be liberated from its combination by very moderate heating. The compounds can be kept for a long time in closed vessels in a slight atmosphere of chloroform, and the salicylid and *o*-homosalicylid can be used over and over again. After becoming acid, through exposure to light, chloroform may be readily regenerated, by agitating it with solution of sodium carbonate, and distilling from a little unslaked lime. From what has been said above, chloroform to be kept for use should have the sp. gr. 1·49, and if denser than this, should be brought to it by the addition of alcohol. It is best kept in cork-stoppered bottles. As the cork is not acted on by chloroform, if it become yellow and softened it will indicate the presence of an acid, and thus act as a test. (*A. J. P.*, 1868, p. 289.)

Official Tests. The U. S. Pharmacopœia directs that "if 20 C.c. of Chloroform be poured upon a clean, odorless filter laid flat upon a warmed porcelain or glass plate, and the plate be rocked from side to side until the liquid is all evaporated, no foreign odor should be-

* In relation to chloroform, see the paper of Soubeiran and Mialhe, *Journ. de Pharm.*, July, 1849, copied into *A. J. P.*, xxi. 313; also the paper of Dr. Gregory, *Chem. Gaz.*, May 15, 1850.

come perceptible as the last portions disappear from the paper, and the paper should be left nearly odorless when compared with a new, odorless filter. If 10 C.c. of Chloroform be well shaken with 20 C.c. of distilled water, and the liquid be allowed to separate completely, the water should be neutral to litmus paper, and should not be affected by silver nitrate test-solution (absence of *chlorides*), or potassium iodide test-solution (absence of *free chlorine*). If to about 5 C.c. of Chloroform, contained in a dry test-tube of the capacity of about 10 C.c., about 4 C.c. of perfectly clear barium hydrate test-solution be added without agitation, and the test-tube be then corked and set aside in a dark place for six hours, no film should be visible at the line of contact of the two liquids (absence of *products of decomposition* in Chloroform which may be otherwise pure). If 40 C.c. of Chloroform be shaken with 4 C.c. of colorless, concentrated sulphuric acid in a 50 C.c. glass-stoppered cylinder during twenty minutes, and the liquids be then allowed to separate completely so that both are transparent, the Chloroform should remain colorless, and the acid should appear colorless, or very nearly colorless, when seen in a stratum of not less than about 15 Mm. in thickness (absence of *impurities decomposable by sulphuric acid*). If 2 C.c. of the sulphuric acid, separated from the Chloroform, be diluted with 5 C.c. of distilled water, the liquid should be colorless and clear, and, while hot from the mixing, should be odorless, or give but a faint vinous or ethereal odor (absence of *odorous decomposition products*). When further diluted with 10 C.c. of distilled water, it should remain clear, and should not be affected by silver nitrate test-solution (absence of *chlorinated compounds*). If 10 C.c. of the Chloroform, separated from the acid, be well shaken with 20 C.c. of distilled water, and the liquid be allowed to separate completely, the watery portion should not be affected by silver nitrate test-solution (absence of *chlorinated compounds*)." "On allowing 20 cubic centimetres to evaporate from a large piece of filter-paper placed on a warm plate, no foreign odor is perceptible at any stage of the evaporation. *Water* which has been shaken for five minutes with half its volume of Chloroform, and separated from the Chloroform, should be neutral to *litmus* (absence of acid), should not afford any color with 1 cubic centimetre of *solution of cadmium iodide* and two drops of *mucilage of starch* (absence of free chlorine), and should not yield more than a very slight opalescence with four drops of *solution of silver nitrate* (absence of chlorides). After shaking *sulphuric acid* with ten times its volume of Chloroform for twenty minutes, and setting aside for fifteen minutes, both the acid and the Chloroform should be perfectly transparent and nearly colorless. 2 cubic centimetres taken from the layer of *sulphuric acid*, and diluted with 5 cubic centimetres of *water*, should remain transparent and very nearly colorless, and should have a pleasant odor. When this liquid is further diluted with 10 cubic centimetres of *water*, and stirred with a glass rod, it should still be transparent and colorless, and the addition of four drops of *solution of silver nitrate* should not cause more than a slightly diminished transparency. *Water* which has been shaken with half its volume of Chloroform, previously treated with *sulphuric acid* as described above, should not afford more than a slightly diminished transparency with *solution of silver nitrate*. (The foregoing four tests indicate absence from the Chloroform of products of its decomposition.) It evaporates without residue (absence of fixed matter)." *Br.* These tests imply the presence of but a minute proportion of alcohol, and the total absence of chlorine and those volatile and empyreumatic substances which constitute the most injurious impurities of chloroform. A heat that would be felt through the bottle, on the admixture of sulphuric acid with chloroform, would evince the presence of too much alcohol or water. The want of discoloration from the contact of the two liquids shows the absence of empyreumatic oily matter; but a very slight discoloration might proceed from the alcohol present, and would not, therefore, be a material objection. A color bordering on that of madeira wine would imply an objectionable amount of impurities. The volatile impurities are less volatile than chloroform, and would consequently be the last to escape on the evaporation of the liquid. Impure chloroform, therefore, leaves a foreign odor behind it when allowed to evaporate from the hand, and especially when from a porcelain plate, in the amount and manner indicated; and if a specimen stand this test well, it may be considered as free from noxious volatile impurity. The slight foreign aroma without pungency, which is given out under these circumstances, is of no injurious significance. It is stated that chloroform made from chloral may be distinguished from other chloroform by its remaining colorless when the sulphuric acid test is employed, and by its leaving no aromatic residue when evaporated, evidences of its absolute purity. It has been claimed that this chloral chloroform does not undergo decomposition, but this has been proved not to be correct. (*A. J. P.*, xlii. 409.)

Medical Properties and Uses. Chloroform, when applied locally, is very irritant and

produces decided pain, which may be followed by some numbness and local anæsthesia. If the chloroform be prevented from evaporating, its prolonged contact with the skin is apt to produce blistering. Taken internally, it is absorbed and acts upon the general system. The rapidity of its absorption, and, to some extent, its general effects, depend upon the method in which it is administered. It is commonly exhibited by the mouth or by inhalation. Taken into the stomach in doses of 15 to 25 drops (0·24–0·38 C.c.), it induces only gastric symptoms, chiefly due to its irritant properties; but when there is excessive flatulence, colic, or gastralgia, it not only causes an increased peristalsis and expulsion of any flatus present, but evinces a distinct local narcotic influence by quieting pain and spasm. Taken in doses of 1 to 2 fluidrachms (3·75–7·5 C.c.), it produces a narcotism similar to that seen when it is administered by inhalation, the narcotism, however, developing and passing off much more slowly than in the latter case. Chloroform, as prepared by Mr. Guthrie, was used internally as early as 1832 by Professor Ives and Dr. Nathan B. Ives, of New Haven, in *asthma*, *spasmodic cough*, *scarlet fever*, and *atonic quinsy*, with favorable results. (*Silliman's Journ.*, xxi. 406, 407.) It was employed by Dr. Formby, of Liverpool, in *hysteria*, in 1838; by Mr. Tuson, of London, in *cancer* and *neuralgic affections*, in 1843; and by M. Guillot, of Paris, in *asthma*, in 1844. The first case in which it was employed in inhalation is related by Professor Ives, of New Haven, under date of January 2, 1832. The case was one of *pulmonic disease*, attended with general debility and difficult respiration, and was effectually relieved. (*Silliman's Journ.*, vol. xxi., Jan. 1832, p. 406.) In March, 1847, the action of the pure substance by inhalation was tried on the lower animals by M. Flourens, and its effects on the spinal marrow described. In November of the same year, Dr. Simpson, of Edinburgh, after experimenting with a number of anæsthetic agents in order to discover a substitute for ether, tried chloroform at the suggestion of Mr. Waldie, and, having found its effects favorable, brought it forward as a new remedy for pain, by inhalation in *surgery* and *midwifery*. The advantages which he conceived it to possess over ether were the smallness of the dose, its more prompt action, more agreeable effects, less tenacious odor, greater cheapness, and greater facility of exhibition.

The usual effects produced by a full dose of chloroform, administered by inhalation, are the rapid production of coma, relaxation of the muscles, slow and often stertorous breathing, upturning of the eyes, and total insensibility to agents which ordinarily produce acute pain. The effect on the heart's action is somewhat variable, but the pulse is usually quickened, with a more or less marked loss of volume and firmness. Sometimes frothing of the mouth takes place, and, more rarely, convulsive twitches of the face and limbs. The insensibility is generally produced in one or two minutes, and usually continues for five or ten minutes; but the effect may be kept up for many hours, provided the inhalation be cautiously renewed from time to time. As a rule, no recollection is retained of anything that occurred during the state of insensibility. In some cases sensibility is distinctly affected before consciousness, but the loss is rarely complete enough to be of any practical value; so that it is almost always necessary to produce unconsciousness before the surgeon can commence his operation. The dose of chloroform for inhalation is a fluidrachm (3·75 C.c.), equivalent to 250 drops, or more, to be repeated in two minutes, if the desired effect should fail to be produced. The most convenient inhaler is a handkerchief, loosely twisted into the form of a bird's nest, which, after having been imbued with the chloroform, is held to the mouth and nose. The use of this simple inhaler insures a due admixture of atmospheric air with the vapor of the chloroform. The patient should always be in the horizontal posture. The moment insensibility is produced, which should be brought on *gradually*, the inhalation should be suspended; and if consciousness return too soon, it should be cautiously renewed. In all cases an experienced assistant should attend to the administration of the chloroform and to nothing else, watching the state of the respiration and pulse. The moment there is the least snoring or failure of the pulse, the vapor should be withdrawn. As shown by Claude Bernard, the hypodermic use of morphine greatly prolongs the anæsthesia caused by chloroform, but the method has not been found of practical value. Even with the greatest care, there is always danger in the anæsthetic use of this agent. The estimate that sudden death occurs once in about 3000 inhalations was first made about thirty years ago, and has been strongly confirmed by subsequent statistics. In very many fatal cases the operation has been a very trifling one, and death has occurred in the most robust persons, and in those who had previously taken the anæsthetic without bad effects. The advantages which chloroform has over ether are in its greater rapidity of action, and in the fact that it is less prone to produce, as an after-effect, much nausea and vomiting. The greater safety of ether, however, more than counterbalances these advantages, so that a

large proportion of surgeons believe the use of chloroform unjustifiable, except under especial circumstances. The reason that ether is so much safer than chloroform lies not chiefly in the greater power of the latter agent, but in the fact that chloroform is directly paralyzant to the heart, whilst ether is primarily stimulant to that viscus. Experiments show that in the lower animals the arterial pressure steadily falls during the administration of the chloroform, whilst under ether it rises, and clinical experience abundantly demonstrates that the effects of these agents upon the circulation in man and in the lower animals are identical. As chloroform accidents usually occur very suddenly, the patient should always be closely watched. In most instances a peculiar pallor of the face is the first evidence of danger. The remedies for the accident are placing the patient at an angle of 45°, with the head downward, or even completely inverting the person, cold air fanned upon the face, cold water poured upon the head, sinapisms to the feet, frictions and heat to the body and extremities, and ammonia to the nostrils. If respiration ceases, the tongue should be seized with the artery-forceps and pulled forward from off the glottis, and artificial respiration vigorously performed. Strychnine and digitalis should be used hypodermically or, if circumstances favor, intravenously. Ammonia water has been injected into a vein with good results. The cautious inhalation of small doses of amyl nitrite has been advantageous. Alcohol should never be used in any form.

In midwifery chloroform is believed to be safer than in surgery, and its use is very extensive. It probably tends to increase the danger of post-partum hemorrhage, but this tendency can be overcome by the administration of ergot after the head has come well down upon the perineum. It is frequently stated that no case of death has occurred from its administration during labor; but this appears to be a mistake. On account of its power of producing muscular relaxation, chloroform is frequently employed in general and local spasms. In setting *fractured bones*, in *reducing dislocations* or *strangulated hernias*, etc., the surgeon frequently employs it, and it is often used by the physician in *hiccough*, *chorea*, *whooping-cough*, *hysteria*, *asthma*, *angina pectoris*, *biliary* and *nephritic colic*, *tetanus*, *poisoning from strychnine*, *hydrophobia*, and *tic douloureux*. In these cases it is superior to ether, when a very prompt action is necessary.

As chloroform is powerfully sedative, and ether powerfully stimulant, it was very naturally supposed that by combining them the depressing effects of the former might be counteracted by the latter; but experience has not confirmed the suggestion of theory in this case, as fatal effects have several times followed the joint administration of the two anæsthetics. This result may be in part explained by the more rapid volatilization of the chloroform, which may cause it to reach the surface of absorption with comparatively little admixture of the ethereal vapor, as suggested by Mr. Robert Ellis. (*Med. Times and Gaz.*, March 9, 1867.) It has been claimed that chloroform which has been purified by the cold process is much less depressant than that of ordinary purity, and in the experiments of R. Du Bois-Reymond (*Therap. Monat.*, Jan. 1892) the residue left after the purification of chloroform by cold, while it did not differ in its action upon the circulation from the pure chloroform, was found to be distinctly more paralyzing to the respiratory centres. Rechter (*Journ. Pharm. et Chim.*, 1892) and others, however, have reached the conclusion that the narcosis produced by Pictet's chloroform does not differ in any way from that commonly seen, and at present writing it does not appear probable that the purification by cold yields practical results commensurate with its cost.

The existence of certain diseases modifies greatly the proper choice of an anæsthetic by the surgeon. When brain tumors or severe chronic or acute diseases of the heart, lungs, pleura, or kidney exist, an anæsthetic should not be employed unless its use be imperatively demanded. In all forms of cardiac diseases, unless it be simple hypertrophy, ether is greatly preferable to chloroform, which agent should never be administered under the circumstances mentioned. In diseases of any part of the respiratory tract, chloroform is superior to ether on account of the severe local irritating effects of the latter agent, which cause it to be very dangerous. Until recently the general opinion has been that chloroform is less dangerous in diseases of the kidney than is ether, but the latest clinical and experimental evidences make it apparent that, whilst ether is dangerous in chronic or acute inflammations of the kidney, chloroform is probably more so.

It seems well established that very many deaths following surgical operations, which have occurred some hours or even days after the recovery of consciousness, have been due to the anæsthetic; and it has been definitely proved that the prolonged use of chloroform is capable of producing wide-spread degeneration of tissue which may fatally involve the heart. In experiments made by Dr. H. C. Wood, Jr., it was found that the exposure of dogs to the constant inhalation of a minute amount of chloroform, not sufficient to produce narcosis, was

followed after some hours of consciousness by death, there having been no restraint or operative procedures during the inhalation.

Locally, chloroform is employed as a very prompt, active counter-irritant and narcotic in *neuralgia*, *colic*, etc., and deep injections of it in the neighborhood of painful nerve-trunks have been practised by Dr. Roberts Bartholow with asserted good effects. M. Fournié has found that the vapor from a mixture of equal measures of glacial acetic acid and chloroform is even more effectual, as a local anæsthetic, than that of pure chloroform, producing complete insensibility of the skin in five minutes, if applied from a bottle heated simply by the hand. (*P. J. Tr.*, 1862, p. 385.) Chloroform, in vapor, may be used as a topical application to the rectum. M. Ehrenreich employed it with success in *tenesmus*. A drachm may be vaporized by the heat of warm water from a bottle, fitted with a flexible tube, inserted into the bowel. Prof. Langenbeck, of Berlin, prefers chloroform to tincture of iodine as an injection for the radical cure of *hydrocele*. *Chloroform ointment* is made by adding twenty parts of chloroform to a mixture of ten parts of white wax and ninety parts of lard, previously melted together, and allowing the whole to cool.

Chloroform may be gelatinized by agitating it with an equal weight of white of egg in the cold. In three hours it takes the gelatinous form. A stronger preparation may be made by shaking together, in a bottle, four parts of chloroform and one of white of egg, and placing the mixture in water at 60° C. (140° F.). In four minutes the gelatinization is completed. *Gelatinized chloroform* may be applied to the skin, spread on linen, or by friction. *Syrup of chloroform* may be made by adding one fluidounce of spirit of chloroform to fifteen fluidounces of syrup.

When an overdose of chloroform is taken by the mouth, it is essential to empty the stomach by the pump or siphon tube, and then treat the case much as in serious narcosis from inhalation. In a case of suicide by swallowing chloroform, in which death took place in about thirty-four hours, the lining membrane of the larynx and trachea was found inflamed, the bronchi were loaded with a dirty-gray purulent fluid, the lungs were inflamed as in the first stage of pneumonia, and the brain and its membranes congested; but these morbid appearances are not constant.

In relation to the preparations, consisting of chloroform and alcohol, which have been used under the name of "chloric ether," the reader is referred to *Spiritus Chloroformi*.* (See, also, *Aqua Chloroformi*, *Emulsum Chloroformi*, and *Linimentum Chloroformi*.)

CHONDRUS. U. S. Chondrus. [Irish Moss. Carragheen.]

(KHŎN'DRUS.)

"Chondrus crispus, Stackhouse, and Gigartina mamillosa, J. Agardh (class, Algæ)." *U. S.*

Carragheen, *P. G.;* Caragahen, Fucus Crispus; Carragaheen, Mousse marine pertée, *Fr.;* Irländisches Moos, Perlmoos, Knorpeltang, *G.*

Gigartina. Gen. Ch. Fronds fleshy, cartilaginous, compressed, composed of an internal layer of longitudinal, slender, anastomosing filaments, which pass horizontally outward and divide dichotomously into short moniliform filaments, the whole set in a gelatinous substance; antheridia in superficial spots; tetraspores conciate, densely aggregated, forming spots just below the surface, cystocarps borne in external conceptacles.

Chondrus. Gen. Ch. The same as gigartina, except that the cystocarps are immersed.

Chondrus crispus. Greville, *Alg. Brit.* 129, t. 15; *B. & T.* 305.—*Sphærococcus crispus.* Agardh.—*Fucus crispus.* Linn. The *Irish moss*, or *carrageen* as it is frequently called, consists of a flat, slender, cartilaginous frond, from two to twelve inches in length, dilated as it ascends until it becomes two or three lines in width, then repeatedly and dichotomously divided, with linear wedge-shaped segments, and more or less curled up so as to diminish the apparent length. The capsules are somewhat hemispherical, and are embedded in the disk of the frond. The plant grows upon rocks and stones on the coast of Europe, and is especially abundant on the southern and western coasts of Ireland, where it is collected. It is also a native of the

* *Chlorodyne.* An empirical remedy under this name was first used in London, but is now in some of its imitations very largely employed in various parts of the world. Many formulas are extant. The following has been extensively used in Philadelphia. Morphine hydrochlorate 8 grains, water f ℥ss, hydrochloric acid f ℥ss, chloroform f ℥iss, tincture of cannabis indica f ℥i, hydrocyanic acid, U. S. P., ♏xii, alcohol f ℥ss, oil of peppermint ♏ij, oleoresin of capsicum ♏i. The morphine hydrochlorate and water are heated in a flask with the hydrochloric acid until a clear solution is produced, then the other ingredients are mixed together, and when the first solution is cold the mixture added to it. This is a dangerous remedy, and should be used with great care in three- to ten-drop doses for an adult. (See *Mistura Chloroformi et Opii*, PART II., *National Formulary.*)

United States, and is said to be gathered largely on the southern sea-coast of Massachusetts, where it is partly torn from the rocks and partly collected upon the beach, on which it is thrown up during storms. It is prepared for market by spreading it out high on the beach, to dry and bleach in the sun. (Aug. P. Melzar, *Proc. A. P. A.*, 1860.) An elaborate account of the plant, of its distribution on the sea-coast of Massachusetts, and of the mode of gathering and curing it is given by Mr. G. Hubert Bates, of Scituate, Mass. (*U. S. Agricultural Report*, 1866; also *A. J. P.*, 1868, 417.) See also T. S. Wiegand's account of the industry. (*A. J. P.*, 1895, 596.)

Gigartina mamillosa, Ag. *Phycologia Britannica*, Pl. 199, resembles the true Irish moss, and, growing with it upon the rocks, is often gathered with it. It can, however, be at once distinguished by the numerous papillæ which cover the surface and margins of the fronds and bear the fruit (cystocarps). In chemical and medicinal properties it is probably identical with *C. crispus*.

Irish moss when collected is washed and dried. It is probably sometimes bleached by the use of potassium permanganate and sodium hyposulphite by the same process as that used for bleaching sponge. (See *Spongia Decolorata*, PART II., *National Formulary*.) Herr Schack was led to suspect this through discovering the presence of sulphurous acid in a German specimen. (*Pharm. Zeitung*, 1886, p. 87.) In the fresh state it is of a purplish color, but, as found in the shops, is yellowish or yellowish white, with occasionally purplish portions. It is officially described as "yellowish or white, horny, translucent; many times forked; when softened in water, cartilaginous; shape of the segments varying from wedge-shaped to linear; at the apex emarginate or two-lobed. It has a slight sea-weed odor, and a mucilaginous, somewhat saline taste. One part of it boiled for ten minutes with 30 parts of water yields a solution which gelatinizes on cooling, and is not colored blue by iodine test-solution." *U. S.* It swells in cold water, but does not dissolve. Boiling water dissolves a large proportion of it, and the solution, if sufficiently concentrated, gelatinizes on cooling. Herberger found 79·1 per cent. of pectin, and 9·5 of mucus, with fatty matter, free acids, chlorides, etc., but neither iodine nor bromine. M. Dupasquier discovered in it both of these elements, which had generally escaped attention in consequence of their reaction, as soon as liberated, upon the sodium sulphide resulting from the decomposition of the sodium sulphate of the moss when charred. (*Journ. de Pharm.*, 3e sér., iii. 113.) The analysis made by Church in 1877 gave: mucilage, 55·4; water, 18·8; mineral matter, 14·2; albuminoids, 9·4; and cellulose, 2·2 per cent. The pectin Pereira thought peculiar, and proposed to call it *carrageenin*. It is distinguished from gum by affording, when dissolved in water, no precipitate with alcohol; from starch, by not becoming blue with tincture of iodine; from pectin, by yielding no precipitate with lead acetate and no mucic acid by the action of nitric acid. M. Ch. Blondeau gives the name of *goëmine* to a substance obtained by boiling carrageen (*goémon*, Fr.) for several hours in distilled water, and precipitating the mucilaginous liquid by alcohol. Flückiger, who analyzed this mucilage with care, found in it *no* sulphur, and only 0·88 per cent. of nitrogen. The drug itself yielded not more than 1·012 per cent. of nitrogen. (*Pharmacographia*, 2d ed., 748.) Haedicke, Bauer, and Tollens obtained, on extraction with water containing 0·6 per cent. of sulphuric acid, and further purification by alcohol, a small quantity of a crystalline compound which resembles galactose in its composition, in its action on polarized light, and in its behavior with nitric acid. On oxidation with nitric acid, the dry moss yields from 21·6 to 22·2 per cent. of mucic acid. Carrageenin is said to have been used as a substitute for acacia, under the name of *imitation gum arabic*; the latter occurs in three forms, white, light yellow, and yellow. They all have similar properties, swelling up like tragacanth when mixed with cold water, but not forming a clear solution unless the mixture be boiled, in this latter respect differing from tragacanth or albumen; iodine does not give a blue color, and alcohol does not precipitate the solution, even when 50 per cent. of it is added. It has mild adhesive properties. (E. C. Federer, *Pharm. Era*, 1887, 146.) The mucilage of Irish moss has come into considerable use as an emulsifying agent. (*Proc. A. P. A.*, 1887; *A. J. P.*, 1888, 170.) (See *Mucilago Chondri*, PART II., *National Formulary*.)

Carrageen is nutritive and demulcent, and, being easy of digestion and not unpleasant to the taste, forms a useful article of diet in cases in which the farinaceous preparations, such as tapioca, sago, barley, etc., are usually employed. It has been particularly recommended in *chronic pectoral affections*, *scrofulous complaints*, *dysentery*, *diarrhœa*, and *disorders of the kidneys and bladder*. It may be used in the form of decoction, made by boiling a pint and a half of water with half an ounce of the moss down to a pint. Sugar and lemon-juice may usually be

added to improve the flavor. Milk may be substituted for water when a more nutritious preparation is required. It is recommended to macerate the moss for about ten minutes in cold water before submitting it to decoction. Any unpleasant flavor that it may have acquired from the contact of foreign substances is thus removed.

CHRYSAROBINUM. U. S., Br. Chrysarobin.

(KHRĬS-Ą-RŌ-BĪ'NŬM.)

"A neutral principle, in its commercial, more or less impure form, extracted from Goa Powder, a substance found deposited in the wood of Andira Araroba, Aguiar (nat. ord. Leguminosæ)." *U. S.* "A substance obtained from Araroba by extracting with hot chloroform, evaporating to dryness, and powdering. It consists chiefly of a definite chemical substance also known as chrysarobin, but contains a varying proportion of chrysophanic acid." *Br.*

The definition of chrysarobin given by the U. S. Pharmacopœia makes it somewhat doubtful what is intended, but the statement of properties and characteristics has led us to consider the name as synonymous with that of chrysarobin of the British Pharmacopœia, which authority very properly recognizes under distinct headings Crude Chrysarobin (Goa Powder or Araroba) and the Purified Chrysarobin. (See *Araroba*, p. 221.)

Properties. "A pale orange-yellow, microcrystalline powder, odorless and tasteless; turning brownish-yellow on exposure to air. Very slightly soluble in cold water or alcohol; soluble, without leaving more than a small residue, in 150 parts of boiling alcohol; also soluble in 33 parts of boiling benzol, and in solutions of the alkalies. When heated to 151° C. (303·8° F.), it fuses, forming a dark, opaque mass; and, when ignited, it is partly sublimed, and finally consumed without leaving a residue. When boiled with about 2000 parts of water (which produces only partial solution), the light reddish-brown filtrate does not affect litmus paper, and is not altered by ferric chloride test-solution. In concentrated sulphuric acid it is soluble with a deep-red color; on pouring this solution into water, the substance is again deposited unchanged. On adding 0·1 Gm. of Chrysarobin to 10 C.c. of potassium or sodium hydrate test-solution, in a test-tube, and shaking the latter, the solution, which is at first yellow or yellowish-red, will gradually acquire a deep-red color." *U. S.* The British Pharmacopœia requires that chrysarobin shall be entirely soluble in hot chloroform, almost entirely soluble in hot alcohol (90 per cent.), and that it shall partially dissolve in a solution of potassium hydroxide with the production of a deep reddish-brown color, and shall, when incinerated, not leave more than 1 per cent. of ash. (See *P. J. Tr.*, 1892, 543.) Chrysarobin in alkaline solution takes up oxygen readily, even from the air, and changes into chrysophanic acid according to the reaction $C_{30}H_{26}O_7 + 4O = 3H_2O + 2C_{15}H_{10}O_4$. The difference in physical properties between chrysarobin and chrysophanic acid is well described by Andouard. (See *Proc. A. P. A.*, 1895, 864.) When chrysarobin is distilled with zinc dust it yields *methyl-anthracene*, $C_{15}H_{12}$. Liebermann has since established clearly the relationship of chrysarobin to chrysophanic acid, as the latter is a dioxymethylanthraquinone, the former is a reduced quinone. Hence its affinity for oxygen, as the reduction products of the quinone class almost always tend to absorb oxygen and again go back to their original condition. Liebermann, in observing the chemical relationship of chrysophanic acid to commercial alizarine and purpurine, was led to study their reduction products (or leuco-compounds), and so discovered a class known as *anthrarobins*, having similar medicinal properties to chrysarobin. (See *Anthrarobin*, PART II.) *Lenirobin*, made by the action of acetic acid on chrysarobin, and described as a tetracetate, and *Eurobin*, the triacetate, are recommended as substitutes for chrysarobin, having the advantage of not staining linen indelibly. (*Merck's Report*, 1898, 466.)

Medical Uses. When taken internally in sufficient amount, chrysarobin acts as a decided gastro-intestinal irritant, producing large, very watery, brownish stools, and repeated vomiting without much nausea. Dr. J. A. Thompson (*N. R.*, 1877, 167) states that it acts efficiently as a cholagogue purgative in doses of from 20 to 25 grains (1·3–1·565 Gm.); but it has failed to secure a place as an internal remedy. Chrysarobin has been long used in South America and India as a remedy in *skin diseases*, but the attention of the general profession was first called to it in 1874 by Sir Joseph Fayrer.* It is frequently applied in *psoriasis* and very *chronic eczema*, by being rubbed up with water into a dough, which is spread over the

* Under the name of *Chrysarobin oxidum*, Unna has highly recommended in *eczema* a 5 to 10 per cent. solution of a substance produced by the action of sodium peroxide upon chrysarobin suspended in boiling water.

diseased spot after it is as far as possible freed from scales by washing. As soon as the dough is dry, it should be covered with a layer of collodion or solution of gutta-percha, and the whole allowed to remain for several days, when it is removed by washing and renewed. In using chrysarobin, care must be observed not to allow it to come in contact with the clothes, as it leaves an indelible stain. It is at present employed largely in the preparation of chrysophanic acid; its action is affirmed to differ from that of chrysophanic acid and to be largely the result of its strong affinity for oxygen, causing it to act as a reducing agent. In *hemorrhoids*, Dr. M. S. Kossobudskji claims to obtain extraordinary results. His method is to first wash off the hemorrhoids with a two-per-cent. solution of carbolic acid or a one-per-cent. solution of creolin, and then, after thoroughly drying them with absorbent cotton, to apply two or three times daily a salve composed of chrysarobin, 12 grains; iodoform, 4½ grains; extract of belladonna, 9 grains; vaseline, 3¾ drachms. In the treatment of internal hemorrhoids he employs suppositories composed of chrysarobin, 1¼ grains; iodoform, $\frac{3}{10}$ of a grain; extract of belladonna, $\frac{1}{7}$ of a grain; cacao butter, 30 grains; with sufficient glycerin to make a smooth mass.

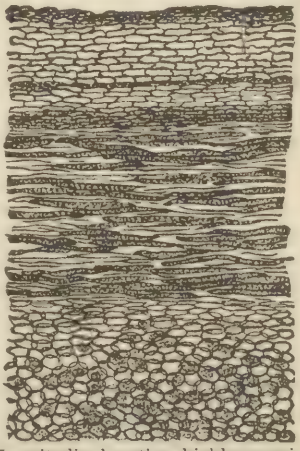
CIMICIFUGA. U. S. (Br.) Cimicifuga. [Black Snakeroot.]

(CĬM-Ĭ-CĬF'Ū-GĄ.)

"The rhizome and roots of Cimicifuga racemosa (Linné), Nuttall (nat. ord. Ranunculaceæ)." *U. S.* "The dried rhizome and roots of Cimicifuga racemosa, Elliott (Actæa racemosa, Linn.)." *Br.*

Cimicifugæ Rhizoma, *Br.*, Actææ Racemosæ Radix; Black Snakeroot; Black Cohosh; Racine d'Actée à Grappes, *Fr.*; Schwarze Schlangenwurzel, *G.*

Gen. Ch. Calyx four- or five-leaved. *Petals* four to eight, deformed, thickish, sometimes wanting. *Capsules* one to five, oblong, many-seeded. *Seeds* squamose. *Nuttall.*



Transverse section of Cimicifuga; rootlet showing five ligneous rays.

Cimicifuga racemosa. Torrey, *Flor.* 219; Carson, *Illust. of Med. Bot.* i. 9, pl. 3.—*C. serpentaria.* Pursh, *Flor. Am. Sept.* p. 372.—*Actæa racemosa.* Willd. *Sp. Plant.* ii. 1139.—*Macrotys racemosa.* Eaton's *Manual*, p. 288; *B. & T.* 8. This is a tall stately plant, having a perennial root, and a simple herbaceous stem, which rises from four to eight feet in height. The leaves are large, and ternately decomposed, having oblong-ovate leaflets, incised and toothed at their edges. The flowers are small, white, and disposed in a long, terminal, wand-like raceme, with occasionally one or two shorter racemes near its base. The calyx is white, four-leaved, and deciduous; the petals are minute, and shorter than the stamens; the pistil consists of an oval germ and sessile stigma. The fruit is an ovate capsule containing numerous flat seeds. The plant grows in shady or rocky woods from Canada to Florida, flowering in June and July.

Properties. The dried root consists of a thick, irregularly bent or contorted body or caudex, from one-third of an inch to an inch in thickness, often several inches in length, furnished with many slender radicles, and rendered exceedingly rough and jagged in appearance by the remains of the stems of successive years, which to the length of an inch or more are frequently attached to the root.* It is officially described as follows. "The rhizome is of horizontal growth, hard, 5 Cm. or more long, about 25 Mm. thick, with numerous stout, upright or curved branches, terminated by a cup-shaped scar, and with numerous wiry, brittle, obtusely quadrangular roots, about 2 Mm. thick; the whole brownish-black, of a slight but heavy odor, and of a bitter, acrid taste. Rhizome and branches have a smooth fracture, with a rather large pith, surrounded by numerous sublinear, whitish wood-rays, and a thin, firm bark. The roots break with a short fracture, have a thick bark, and contain a ligneous cord expanding into about four rays." *U. S.* The roots "exhibit in transverse section from three to five

* For a detailed description of the microscopic character of the root, see *A. J. P.*, 1884, 460; also 1895, 121.

wedge-shaped wood-bundles, separated by as many broad medullary rays. Both rhizome and roots are blackened by *test-solution of ferric chloride* (presence of tannic acid)." *Br.* The odor, though not strong, is peculiar and rather disagreeable, and is gradually lost by keeping. The root yields its virtues to boiling water. Tilghman found gum, starch, sugar, resin, wax, fatty matter, tannic and gallic acids, a black coloring matter, a green coloring matter, lignin, and salts of potassa, lime, magnesia, and iron. (*A. J. P.*, vi.) It no doubt also contains, when fresh, a volatile principle, with which its virtues may be in some degree associated. George H. Davis separated by distillation a small proportion of volatile oil having decidedly the peculiar odor of the root. He also found albumen, extractive, and silica. The sugar noticed by him was of the uncrystallizable variety, and the resin of two kinds, one soluble in alcohol but not in ether, the other soluble in both these menstrua. (*A. J. P.*, xxxiii.) A crystallizable principle has been obtained by Mr. T. Elwood Conard from a strong tincture of the root by treating with solution of lead subacetate, which precipitated resin, tannin, and coloring matters, then filtering, and precipitating the lead by hydrogen sulphide in excess, and allowing the tincture to evaporate spontaneously; and, finally, having treated the residuary powder with benzin, afterwards washing it with water, dissolving it to saturation in strong alcohol, and treating the solution with alumina. The mixture was allowed to evaporate to a dry mass, which was nearly exhausted with alcohol. The solution, being allowed to evaporate, left behind a crystalline mass, somewhat resembling alum. This substance has little taste, on account of its extreme insolubility in the saliva, but in alcoholic solutions has very strongly the acrid taste characteristic of the fresh root. The crystals are very soluble in cold, and more so in hot, alcohol, soluble also in chloroform, and slightly so in ether. They are fusible and inflammable. They are neutral, possessing neither acid nor alkaline properties. Their effects on the system were not examined. (*A. J. P.*, 1871.) L. F. Beach (*A. J. P.*, 1876) obtained from commercial resin of cimicifuga (the so-called cimicifugin or macrotin) a crystalline principle by Conard's process. M. S. Falck (*A. J. P.*, 1884) found in the juice of the fresh plant a crystalline principle resembling the principle announced by Conard. On the other hand, neither F. H. Trimble (*A. J. P.*, 1878) nor Profs. Warder and Coblentz were able to obtain a crystalline principle, while C. S. Gallaher obtained crystals of cane sugar from the fluid extract. (*A. J. P.*, 1887.) In view of these facts, it would appear that the active principle is a resinous amorphous body. (See *Drugs and Medicines of North America*, vol. i.)

Longitudinal section, highly magnified.

Medical Properties and Uses. In 1831 cimicifuga was introduced to the notice of the profession by Dr. Young. In overdoses it is said to cause general relaxation, vertigo, tremors, decided reduction of the pulse; occasionally it vomits, but its emetic action is never violent, and is probably simply the result of a mild gastric irritation. It certainly in large doses produces giddiness, with intense headache and prostration. It has been found by Dr. R. Hutchinson to cause in frogs complete anæsthesia by a direct action upon the sensory side of the spinal cord. The same observer noted that toxic doses produce in mammals slowing of the pulse and fall of the arterial pressure, results which appear to be due in part to a direct depressant action upon the heart-muscle or its ganglia, in part to a paralysis of the vasomotor centre. It has been used in the past in *rheumatism*, *dropsy*, *hysteria*, *phthisis*, and various other affections, but at present is employed almost exclusively in the treatment of the *St. Vitus's dance* of childhood, in which it is an efficient remedy. The dose of the powder is from a scruple to a drachm (1·3–3·9 Gm.). The *decoction* (℥i to Oj) was formerly much used in the dose of two fluidounces (60 C.c.), but is now entirely out of vogue. The dose of the *tincture* is one or two fluidrachms (3·75–7·5 C.c.). The *fluid extract* is, however, the best preparation; dose, from one-half to one fluidrachm (1·9–3·75 C.c.) three or four times a day in water. The *extract* is efficient, and has the advantage that it can be administered so as to be practically free from taste in pilular form. The practitioners calling themselves eclectics use, under the name of *cimicifugin*, or *macrotin*, an impure resin obtained by precipitating a saturated tincture of the root with water; dose, a grain or two (0·065–0·13 Gm.). (See *N. J. Med. Rep.*, viii. 247.)

CINCHONA. U. S. (Br.) Cinchona.

(CIN-ĢHŌ'NA.)

"The bark of Cinchona Calisaya, Weddell, Cinchona officinalis, Linné, and of hybrids of these and of other species of Cinchona (nat. ord. Rubiaceæ), containing not less than 5 per cent. of total alkaloids, and at least 2·5 per cent. of quinine [$C_{20}H_{24}N_2O_2 + H_2O = 341·3$]." *U. S.* "The dried bark of the stem and branches of cultivated plants of Cinchona succirubra, Pavon. When used for purposes other than that of obtaining the alkaloids or their salts, it should yield between 5 and 6 per cent. of total alkaloids, of which not less than half should consist of quinine and cinchonidine, as estimated by the following methods." *Br.* (See p. 411.)

S.* "The dried bark of the stem and branches of cultivated plants of Cinchona succirubra, Pavon." *Br.*

Botanical History.

Though the Peruvian bark was introduced into Europe so early as 1640, it was not till the year 1737 that the plant producing it was known to naturalists. In that year La Condamine, on a journey from Quito to Lima, through the province of Loxa, had an opportunity of examining the tree, of which, upon his return, he published a very complete description, with plate, under the name *Quinquina*, stating that three species were recognized. (*Mém. Ac.*, Paris, 1738, p. 226.) Four years later, Linné, without justification, proposed a new name, *Cinchona*, in honor of the Countess of Chinchon, who first made the bark known in Europe. Although the original name has been adopted by several authors, the synonyme Cinchona appears in most writings, and the species are at present arranged under that name. Under the rules of nomenclature adopted at the Genoa Congress in August, 1892, the necessity of restoring the name Quinquina is avoided, and we retain the later name Cinchona. Linné recognized but one species, which he called *C. officinalis*, and this continued for a long time to be recognized by the Pharmacopœias as the only source of the Peruvian bark of commerce. But a vast number of plants belonging to the Linnæan genus Cinchona were in the course of time discovered; and the list became at length so unwieldy and heterogeneous that botanists were compelled to distribute the species into several groups, each constituting a distinct genus, and all associated in the natural family of Cinchonaceæ. Seventy-three of those which may be denominated *False Cinchonas* have been enumerated by Weddell. The botanical characters distinguishing the true Cinchonas from the related groups, according to the classification of Bentham and Hooker, are exhibited in the following table:

Cinchoneæ. Corolla-lobes valvate, imbricate, or contorted. Ovary 2-celled, ovules very many in each cell. Fruit capsular. Seeds numerous, minute, vertical or ascending, peltate, imbricate, winged, albuminous; radicle almost always superior. Trees or shrubs, the stipules (except in Hillieæ) entire.

Subtribe I. EUCINCHONEÆ.—Corolla valvate.

Subtribe II. HILLIEÆ.—Corolla imbricated or contorted.

I. EUCINCHONEÆ.

* Placentæ adnate to the middle of the septum.

** Placentæ ascending or erect from the base of the septum.

*** Placentæ pendulous from the apex of the cells.

*

† Capsule septicidal, the valves occasionally bifid.

†† Capsule almost always loculicidal.

†

1. *Cinchona.* Panicles terminal. Corolla-lobes pubescent on the margins. Capsules dehiscent from the base upward.

2. *Cascarilla.* Panicles terminal. Corolla-lobes papillose on the margins. Capsules dehiscent from the top downward.

3. *Remijia.* Panicles or racemes axillary, interrupted.

1. *Cinchona*, L.

Calyx-tube turbinate, pubescent; limb 5-dentate, persistent. Corolla hypocrateriform, pubescent, the tube terete or nearly so, the limb 5-lobed, spreading, smooth within, the margin pilose, valvate. Stamens 5, inserted into the tube of the corolla, the filaments short or elongated; anthers included, or the apex exsert, dorsifixed, linear. Disk pulvinate. Ovary 2-celled; style slender, the branches short, obtuse, within papillose, inserted or sub-exsert. Evergreen trees or shrubs, the branchlets terete or 4-angled. Leaves opposite, petiolate. Stipules interpetiolar, the base glandular within, deciduous. Flowers white, purple, or flesh-colored, fragrant.

For our knowledge of these plants as they existed naturally, we are chiefly indebted to the following botanists, besides La Condamine, of whom we have before spoken: Joseph de Jussieu, who in the year 1739 explored the country about Loxa, and gathered specimens still existing in the cabinets of Europe; Mutis, who in 1772 discovered Cinchona trees in Colombia, and afterwards, aided by his pupil, Zea, made further investigations and discoveries in the same region; Ruiz and Pavon, who in 1777 began a course of botanical inquiries in the central portions of Lower Peru, and discovered several new species; Humboldt and Bonpland, who visited several of the Peruvian bark districts, and published the results of their observations after 1792; Pöppig, who travelled in Peru so late as 1832, and published an account of his journey about the year 1835; Weddell, whose researches in Bolivia are so well known and have been so productive of valuable information in relation to the Calisaya bark and allied species; whilst Karsten, Caldas, Martius, Ledger, Markham, and other intrepid explorers have in later times largely added to our information. The conclusions concerning the relations of the many forms, based upon the observations and collections of the above-named travellers, have undergone important modifications in view of the behavior of the plants under cultivation. The specific classification of the Cinchonas has always presented great difficulties, owing to the different relative values ascribed by different authors to the several structural characters. Under cultivation it has been seen that these characters are extremely variable, owing partly to the natural tendency of the species to develop strongly-marked varieties, and partly to the great freedom with which they hybridize. While these tendencies have been stronger in the cultivated plants, they have evidently not been wanting in a state of nature. Thus we have come to place an entirely new estimate upon the supposed specific characters, and modern authors have been led to deny specific rank to many of the formerly accepted species. The extreme view is that of Dr. Otto Kuntze, who recognizes but four full species. This view is probably shared by no one, but Dr. Kuntze's general conclusions concerning the great extent of hybridization, and its influence in the production of new forms, are undoubtedly sound.* The writer's studies in the Bolivian plantations led him independently to the same conclusions. Any specific classification, however carefully worked out, must be considered to some extent as matter of opinion merely.

Probably the most satisfactory classification is that of Weddell, revised in 1870. (*Ann. d. Sci. Nat.* 5th series, vols. xi. and xii.) Messrs. Bentham and Hooker, in the *Genera Plantarum*, admit the existence of about 36 species, but this number appears entirely too large. The most of the species no longer possess more than a botanical and historical interest, as, under the changed conditions brought about by cultivation, their products are no longer collected for the market. The species which have been brought under cultivation for commercial purposes are alone named in the following list. Even this short list has been still further reduced as experience has determined the few species and forms which can be most profitably cultivated. Hence only the four species Nos. I., II., V., and VI. of the list, which with their hybrids furnish almost all our bark at the present day, are here described:

I. C. officinalis.
  var. Condaminea,
  " Bonplandia,
  " crispa,
  } yielding crown bark.

II. C. succirubra, yielding red bark.

III. C. pitayensis,
  C. lancifolia,
  C. cordifolia,
  } yielding Colombian bark.

IV. C. nitida,
  C. micrantha,
  C. peruviana,
  } yielding gray bark.

V. C. calisaya,
VI. C. ledgeriana,
  } yielding yellow bark.

* The principal sources of information bearing on this phase of the subject are the several reports of the plantations in Java, India, and Jamaica, Howard's *Quinology of the East Indian Plantations*, Markham's *Peruvian Bark*, Kuntze's *Arten, Hybriden und Cultur der Chininbäume*, Hooper in the *Pharmacographia Indica*, several contributions by Trimen to the *Tropical Agriculturist*, and Prof. Rusby in the *Pharmaceutical Record*, Oct. 1887.

C. calisaya, Weddell (*Hist. Nat. des Quinquinas*, p. 30, t. 3). Tree tall, usually surpassing those about it, the trunk often more than 2 feet in diameter. Leaves petiolate, the blade ovate-oblong to slightly obovate, 3 to 7 inches long by 1 to 3 inches broad, obtuse, the base acute or slightly attenuated, very thin, smooth, and, especially below, with a satiny lustre, above dark green, below emerald-green or deep purple-green, scrobiculate, the glands scarcely visible above. Stipules oblong, about equalling the petioles, very smooth, very obtuse. Panicles ovate to subcorymbose. Calyx pubescent, with a cup-shaped limb and short triangular teeth. Corolla rose-colored (in cultivation often white or nearly so), the tube cylindrical and about 4 lines long, the laciniæ more deeply colored, the edges white-hairy. Stamens included. Capsule ovate, scarcely as long as the flowers. Seeds elliptical lanceolate, the margin irregularly fimbriate-toothed. Bolivia and Southern Peru, 4000 to 6000 feet. Source of the Calisaya or Yellow Bark. The species presents many forms, and two varieties are recognized.

Var. ledgeriana, Howard, differs from the type chiefly in its thicker, narrower, oblong leaves, with attenuate base, often bluish-green below. It yields a thick and remarkably rich bark, and is probably the most valued of all the cinchonas. Specific rank has been strongly claimed for it.

Var. microcarpa, Weddell, is very similar to the last, with a firm leaf and short pod. It also yields a rich bark. It is not at all improbable that the accepted name "ledgeriana" of Howard is a mere synonyme for the older name *microcarpa* of Weddell.

The *var. josephiana*, so called, has in reality nothing to do with this species, nor with any other. It is distinct, and yields a thin and worthless bark. In Bolivia it is known as "*Pajinal*," and its presence in the plantation constitutes a serious difficulty. In appearance the plant is considerably like the ledgeriana, with which it hybridizes freely, and the two, with their hybrids, have been apparently much confused in all plantations except those of Bolivia. Ledgeriana has a tall and slender habit, with a small crown, while Josephiana is shorter and broader, less symmetrical, and generally coarser. The branchlets of the former are blackish, those of the latter bright red.

C. succirubra, Pavon, Mss. (Howard in *Pharm. Journ.*, Oct. 1856, p. 209, with a figure). Extreme size even greater than that of the last. Branches silvery. Petiole pubescent, leaf ovate to oval, acute with a very short point, the base more or less narrowing, often 6 by 9 inches, dark green and smooth above, below paler and pubescent to a variable degree, especially on the veins, not scrobiculate, the margin slightly revolute. Stipules entire, oblong, obtuse, sub-amplexicaul. Flowers much as in the last, but rather smaller. Fruit lanceolate. Western slopes of Mt. Chimborazo. The source of the Red Bark.

C. officinalis, Linné (*Sp. Pl.*, ed. i., p. 172). Petioles smooth, cylindrical, and, like the veins, reddish; blade 4 to 5 inches long, varying from broadly oval to lanceolate, acute at both ends, the margins usually recurved, smooth and deep green above, paler, but bright green below, scrobiculate, the principal veins pubescent. Stipules equalling the petioles, ovate, acute, entire, pubescent. Flowers and fruit much as in *C. calisaya*. Widely distributed in the equatorial Andes, at an elevation of from 5000 to 7500 feet. The source of the barks known as Pale, Crown, Loxa, Cuenca, and Huanuco. This is the original species, upon which the genus Quinquina or Cinchona was founded. All things considered, it is, perhaps, to be regarded as the principal species of the genus. Its variability is extreme, and it is doubtful if any two authors can be found who agree perfectly as to its limits. The forms of no other species have suffered such vicissitudes of nomenclature as have those of *C. officinalis*. Those which to one author appear easily included within it, in the hands of another serve as types of quite a group of species and varieties. The classification of our present supplies of bark is, however, not materially affected by these considerations.

The specific variations produced by hybridization in the above characters may not be here considered, though it may be stated that they are entirely characteristic. The parentage of a hybrid is ordinarily fully and strongly indicated in its appearance. As a rule, also, the alkaloidal yield takes a mean between that of the parents, but sometimes this is conspicuously not the case.

Geographical Distribution.

The genuine Cinchona trees are natives exclusively of South America. In that continent, however, they are widely diffused, extending from the 19th degree of south latitude, considerably south of La Paz, in Bolivia, to the mountains of Santa Marta, or, according to Weddell, to the vicinity of Caracas, on the northern coast, in about the 10th degree of north latitude. They follow, in this distance, the circuitous course of the great mountain ranges, and for the most part occupy the eastern slope of the second range of the Cordilleras. Except northward from Guayaquil, or a very little to the southward of that latitude, the growth of the cinchona, other than upon the eastern slopes of the Andes, is impossible even under cultivation. Elsewhere both the western slope and the plateau are entirely too dry or too cold for these plants, which require a moderate and equable temperature and an abundant and fairly constant supply of water. Irrigation cannot supply the place of a humid climate, for the atmosphere as well as the soil must be well charged with moisture. A certain amount of dry weather is, however, required for the ripening of the capsules. Free drainage is an important condition. Mr. Cross and others, who have personally inspected the region in the Andes where the best barks are obtained, have found the Cinchona trees only on the well-drained slopes, and never on wet ground. With regard to temperature, Mr. Cross found that in the region of the *C. officinalis* the variation was from 34° to 70° F., a fall below 40° or a rise above 65° being rare, and the mean range being from 45° to 60°. Messrs. Humboldt and Caldas place the figures several degrees higher.

For the Red Bark region, Dr. Spruce gives the following table:

Mean minimum	61½° F.
Mean maximum	72⅕°
Highest observed	80½°
Lowest observed	57°
Mean daily variation	10½°

For the Calisaya region, Mr. Markham gives the following table:

Mean temperature	69⅘° F.
Highest observed	75°
Lowest observed	56°
Mean daily variation	10½°

An environment suitable for the Cinchona is adapted to such plants as the most elevated of the palms and bamboos, the tree-ferns, arborescent Melastomaceæ, fuchsias, begonias, epiphytic orchids, and the Erythroxylon coca. The limits of altitude and climatic conditions are closely drawn. In the most southern districts, the trees descend to about 2500 feet, while in the warmest regions they scarcely ascend to the 10,000-foot level. The individual species are for the most part rigidly restricted as to altitude and latitude, and, indeed, it has not always been found easy to detect the climatic conditions which would cause one species or variety to thrive while another very near it would languish. This is especially true of the more valuable forms. The actual distribution of the more important species is best displayed by the accompanying map, taken from Markham's work entitled "Peruvian Bark."

THE CINCHONA REGIONS OF SOUTH AMERICA.

It is to be noted that at present the stocks of wild barks have been enormously reduced, as detailed under Commercial History. Indeed, in certain sections, as the Calisaya district, the tree was practically exterminated in the wild state, so far as relates to a bark-supply.* From the far interior, however, occasional bales of wild Calisaya have been received. The low price of cultivated bark since 1885 has resulted in checking the destruction of the wild trees, which have begun again to multiply, so that they may possibly become once more common or even abundant. The Crown Bark region of Ecuador is still fairly productive, and in Colombia and Venezuela there are vast supplies of more or less inferior barks which await some favorable change in the market—never very likely to take place—that will render their collection profitable. Even at present a limited and irregular supply of one of these barks is furnished. With the exceptions here noticed, our present supplies of bark are entirely the product of cultivation, to which, therefore, we must give our chief attention.

Cultivation and Production.

The alarming prospect of the failure of the supply of Cinchona bark (see Commercial History) induced Europeans, about the middle of the present century, to turn their attention to the possibility of introducing the trees to cultivation. So early as 1737, La Condamine had collected a large number of young plants, with a view of conveying them to Europe; but, after having descended the Amazon in safety for more than a thousand leagues, they were washed overboard, near the mouth of that river, from the boat containing them, and were all lost. After this failure, though the idea of transplanting the Cinchonas was occasionally suggested,

* The writer, while travelling in Bolivia, in 1886, used to listen to the evening conversation of his Indians, who would describe with deepest earnestness some locality, perhaps many leagues distant, where a small tree might be found standing; but all his efforts, supplemented by the promise of liberal rewards, were not sufficient to secure good-sized specimens of wild bark.

nothing was done until 1846–47, when Dr. Weddell, now celebrated for his successful exploration of the region of the Calisaya bark, sent some seeds to France, which were planted with success in the Jardin des Plantes, and thus supplied some of the conservatories of Europe with specimens of the plant. But the first successful effort with a view to great practical results was made in 1853 by the Dutch government, by which Mr. Hasskarl, formerly superintendent of the Botanical Garden in Java, was sent to South America on this important mission. A number of young Cinchona plants were forwarded by him directly across the Pacific to Batavia, which they reached before the close of 1854. From these, and from seeds obtained from other sources, which were planted in the mountains of Java, in sites selected for their supposed conformity in climate with the native locality of the Cinchona, have sprung the most important plantations now in existence.

Stimulated by the suggestions of Dr. Royle, and by the partial success of the Dutch, the English government engaged, in 1859, the services of Mr. (now Sir) Clements R. Markham, who proceeded to Bolivia, in South America, and, after almost incredible hardships, arising partly from the nature of the country and partly from the jealousy of the native authorities, succeeded in collecting and transmitting to England upwards of 400 Calisaya plants. Most of these, however, were so much injured on their way from England to India, by the excessive heat of the Red Sea, that very few, on their arrival in Hindostan, had sufficient life remaining to grow when planted. Happily, the deficiency was supplied by seeds of *C. calisaya* sent from Java, where they were produced, to Calcutta, at the request of the English Governor-General. (De Vrij, *P. J. Tr.*, 1863, p. 440.) Whilst Mr. Markham was in Bolivia, other agents were collecting other species in Peru and Ecuador, whence seeds of the pale and red bark Cinchonas reached India, and, being planted in the selected sites, proved to be very productive.

Careful attention to the conditions of growth enumerated under Geographical Distribution was found essential in the selection of sites for the plantations. Those selected were near the Sanitary Station of Ootacamund in the Neilgherry Hills of Southern India, at heights varying from 5000 to 7450 feet. These positions unite the peculiar characters of the native region of the Cinchonas in the Andes, not only as regards elevation and latitude, but also as to atmospheric moisture. Other sites were selected for experimental plantations; and since the first introduction of the Cinchona trees, their culture has been extended to various points from Hakgalla, in the island of Ceylon, to the Himalaya Mountains,—as in the Wynaad, the Coorg, the hills of Travancore, and especially at Peermede in the Presidency of Madras; in Sikkim and Darjeeling in the Presidency of Bengal; at Lingmulla in the Presidency of Bombay; and in the valley of Kangra in the Punjab,—from the southern to the northern extremity of British India. Outside of India and Ceylon, culture by the British has been undertaken in the West Indies, particularly Jamaica, in Guiana, and in the Fiji Islands. The first plants taken by Weddell from Peru to Paris all perished, but the French afterward established plantations in the Isle of Bourbon, at Guadeloupe, and in Algiers, none of which are now known to exist. The Portuguese have established plantations upon the west coast of Africa, and these now yield considerable quantities of bark. Very extensive plantations have been formed, chiefly by the Germans, in Bolivia. A rather large plantation in Colombia is now old enough to be productive. In Mexico and Central America various attempts to introduce the industry have been made. The question of introducing it into the United States has frequently been raised, both officially and otherwise. But it may be stated that there is no spot in North America where the conditions warrant the slightest hope of success in this direction.

The history of Cinchona cultivation affords a striking illustration of the importance of government aid in the establishment of a new industry of this kind. The early and repeated disappointments and failures, owing to the natural obstacles in the way of securing stocks, and to an almost total ignorance of the conditions determining the successful propagation and growth of the plant, and the composition of its bark, were such as to have discouraged the most hopeful of private enterprises. Repeated and expensive expeditions were necessary before the first transplantings were accomplished, and these stocks were preserved and propagated only through the instrumentality of well-appointed public gardens and plantations. In Java, after these early difficulties had been surmounted and success apparently attained, it was found that owing to cross-fertilization much of the progeny was entirely worthless, and the work of propagation had to be begun anew. The same difficulty was encountered elsewhere, and the slow and expensive method of propagation by cuttings was largely resorted to. In Ceylon the public were slow to become interested, and the officials were obliged not only to give away the young plants, but to solicit experiments with them as a personal favor. In Jamaica

a hurricane visited the young and flourishing plantations and almost completely destroyed them. But at length, in spite of all, not only were thriving and permanent government plantations established, but private capital and enterprise upon a vast scale were enlisted.

Sharp competition has largely determined the relative degrees of success attained in the cultivation of Cinchona in the different localities. The consumption of the bark is not to be compared with that of breadstuffs or clothing or building material, being, after all, quite limited, and capable of being readily met by almost any one of the contributing countries. Hence that country that can produce and market the bark at the lowest price, all things considered, may totally destroy the industry in other localities, even though these may be by nature admirably adapted to its production, as witness the partial case of Bolivia. Of prime importance in affecting this result is the cost of labor, so much lower in the East than in any portion of America. Its influence acts in more ways than at first appear. Not only does it give an advantage in the cultivation and marketing of the product by original methods, but it permits the introduction of new methods which greatly increase both the amount and richness of the bark. When it is remembered that it costs no more to market, and but a trifle more to extract, a rich bark than a poor one, so that the market value of the bark increases more rapidly than its percentage yield, it will be seen how immense is the advantage to a producing district of being able to utilize cheap labor in improving the quality of the product. In proximity to market India and Java again possess an advantage over the South American countries, whence the bark must be transported—largely by human porters—across the Andes, over the worst of roads, and these impassable during a large portion of the year.* The ability to extract the bark upon the spot is capable of largely counterbalancing a lack of market facilities; but it so happens that this advantage also inures to the benefit of the Eastern countries. Originally undertaken in India for the purpose of affording a cheap antiperiodic (the crude alkaloids known as "*febrifuge*" or "*quinetum*"), home extraction has become a most important industry, and has assumed various forms. The experiment of extracting the Java bark at the point of production is now under way, if indeed it cannot be said to have already been decided successfully. An excellent product has been placed upon the market, and the conditions for financial success appear favorable. Through the influence of the above conditions the locations of the important industry of Cinchona cultivation have been gradually wrought out. Of the districts of cultivation named above, we may exclude from consideration as appreciably affecting the market all except Java, Ceylon, India, and Bolivia. Of these important centres of production the relative standing has during late years undergone great changes.

Without attempting an analysis of the data on which this table is based, we would refer to the following important conclusions by which the student is impressed. (1) South America, from being the original and only source of supply, has come to yield in 1890 only about five per cent. of the world's supply. (2) Of this small amount, but an insignificant portion is from the wild trees, a consideration which has a most important bearing upon the character and quality of recent supplies. (3) The steady and rapid increase in Java production in the face

* Large planters in Bolivia informed the writer that the cost of collecting, drying, and marketing their bark was not far from one English shilling per pound, exclusive of all cost of production. That some way must have been since found for greatly reducing this expense is evident, for much of the bark has sold at prices below this figure.

of depression and positive decline elsewhere. (4) The great increase in the ratio of private to government production.

The first shipment from Java was of 900 pounds, in 1869. It is to be remembered that a great part of the Indian product is not exported. The total acreage now devoted to cinchona culture is estimated at 63,491, and the number of trees at 73,540,000.

Character of Stocks. It is most important that we should have some knowledge of the varieties of Cinchona composing the stocks in the several producing districts. Unfortunately, it is difficult to obtain from all the countries statistics in such form as will allow of their being presented in a table. *Ceylon.*—All that Mr. Ferguson, in his *Ceylon Hand-Book and Directory* (1890–91), is able to say of the 19,500,000 trees existing there is that "a good deal of attention has been given to the hybrids Robusta magnifolia allied to Crown, and pubescens [*not the species pubescens*] allied to Red bark trees; and the Crown *officinalis* barks in the higher districts 5000 feet upwards; to Ledgerianas grown from seed originally received from Mr. MacIvor off Ledger's trees and from Java and Sikkim in the lower districts, and to Calisayas (Morada and Verde) grown from seed direct from South America; but still we suppose that in number planted out 'Succirubra is king;' it grows at nearly all elevations from 1500 feet upwards." *India.*—In 1889 the trees upon 1779 acres of government plantation in Madras were as follows: officinalis, 981,918; hybrids, 655,856; succirubras, 70,693; calisayas, 273; other kinds, 915. Upon 3000 acres of government plantation in Bengal, with six million trees, Calisayas and hybrids represent by far the greater part, replacing as rapidly as possible the succirubras, owing to a successful method of extracting quinine sulphate instead of the febrifuge as heretofore. Private plantations are estimated to contain 9799 acres, and here the tendency is even stronger towards the rich calisayas, ledgerianas, and hybrids. *Java.*—The report of the government plantations for the second quarter of 1891 gives ledgerianas, 2,659,000; succirubras, 1,076,000; officinalis, 52,900; calisayas, 2200; lancifolias, 1500. Of the three last named, none were apparently being propagated. Regarding the small number of calisayas, it is to be remembered that ledgeriana is practically of this species, and its richest form. *South America.*—The comparatively small supplies of uncultivated bark proceed almost wholly from *C. officinalis* and its varieties and one other species not definitely known. The cultivated is wholly from *C. calisaya*, professedly of pure blood, any hybridization being purely accidental, sought to be avoided by the planters, and occurring with worthless varieties. Before considering the quality of these barks it is desirable to refer briefly to the methods of cultivation, to which such quality is largely owing.

Methods of Cultivation.

The history of Cinchona cultivation teems with evidence as to the difficulty of obtaining pure seeds, owing to the tendency of the plants towards cross-pollination. In every locality where the industry has been established has the disgust of the gardener been excited by the discovery that the plants which he had reared with great care, and upon which he had based great expectations, were contaminated by the admixture of foreign pollen. This was especially true in case of the earlier attempts, before this tendency had become known. Experience at length established the fact that absolute isolation of the seed-trees was essential. One of the curious developments of these experiments was the fact, already referred to, that the value of the progeny was not always assured by the value of its parentage. Some of the hybrids, even when least expected, would develop a surprisingly rich yield; and this tendency has been utilized to develop the most valuable stocks in existence. So certain is it that some of the plants from the best of seed will prove worthless, that the careful selection of the seedlings while young is deemed necessary, and in South America, at least, all planting contracts are based upon this expectation, the contractor not being paid for his work until the plants have become old enough to show with certainty the proportion of good plants contained. Both in the selection of the young seedlings and the acceptance of the plantation, the test of identity is found in the leaf. Propagation by cuttings, extensively practised in some localities, has been found too slow and expensive to become general. A thorough preparation of the soil is as beneficial in the case of Cinchona as in that of other crops. Thorough tillage after transplantation is also essential, a free growth of weeds meaning destruction to a large part of the young trees. The cultivation of a secondary crop between the rows of trees is, however, practicable. A large percentage of profit depends upon the selection of a suitable age for collecting the bark. There comes a time when the use of the ground for starting a new crop is more valuable than the gain by permitting the present crop to remain, and after some years an actual deterioration of the bark sets in. This age is not the same for all the trees in the plantation. Several years'

difference may occur in the maturing of trees germinated at the same time. In the case of calisaya it occurs at from 6 to 9 years from seed, and its indication is the "chicken-leg" scaliness of the bark, as described under Classification. The officinalis matures somewhat less early. In the Bolivian plantations the most experienced hand is selected as the marker, and the cutters follow him, peeling the trees which he has indicated. How far these careful methods of selection are followed elsewhere, the writer is not informed.

Four principal methods of collecting the bark are in vogue, these being variously modified in different sections. The first is *uprooting*, the most primitive, by which the trees are simply uprooted at the proper age, and the ground replanted. The barks of root, stem, and branches are preserved and marketed separately. The second method is *coppicing*, by which, after peeling a quill from the lower portion of the trunk, the latter is cut a few inches from the ground and the remainder of the stem bark and the branch bark are removed. The "coppice" is formed by a second growth of two shoots from each of the stumps. A second coppice is commonly grown, and this is harvested by uprooting. By the third method, *scraping*, the outer bark is scraped off, leaving the liber untouched. This has been found especially applicable to young trees, in which the second growth of bark is rapidly formed and contains 20 to 30 per cent. more alkaloid than that which has been taken off. It seems to be a general opinion among the planters that shaving checks the growth of the tree after it is 5 years old, so that from 3 to 5 years is the age at which it is best practised. The fourth method is known as *mossing*. It having been noticed that the Cinchona alkaloids, especially in any other form than that of sulphate, were apt, on exposure to the direct light of the sun, to become reddened by the generation of coloring matter, at the expense of the alkaloid, it was a very natural inference that a similar change might take place in the living plant, as a consequence of which the proportion of alkaloids they were capable of producing might be greatly diminished. It was also observed that the bark upon that side of the tree where the sun struck it was less rich than that upon the shady side. To obviate this presumed effect, Mr. MacIvor was induced to make the experiment of covering the stems of the growing trees with a layer of moss, so as completely to protect the bark against the influence of sunlight. The result was favorable beyond all expectation; and the yield of the bark thus protected in alkaloids is said to be doubled, tripled, or increased even in larger proportion. A tree can thus be made continuously productive; for if a slip is removed longitudinally from the trunk, from top to bottom, by covering the decorticated portion with moss, the bark is renewed at least as rich as previously in the alkaloids, while from time to time other strips may be taken, till the whole of the old bark is removed, and the new ready for removal by a repetition of the same process; and the tree is thus preserved indefinitely, probably for the whole normal length of its life. Hooper says that renewed bark is always of greater value than the mossed, and mossed than the natural, so long as the trees are under 20 years old, for it has been found that after that time the bark ceases to thicken, and the alkaloids remain stationary or even decrease. Perhaps 20 years is even too old. The practical difficulty with the process is that it requires skilled workmen, not always attainable, and hence the "coppicing system" still largely prevails in India. The supplies of suitable moss accessible to the Indian plantations having become exhausted, recourse was had to grass, old rags, paper, straw, hay, etc., all of which have been found to serve the same useful purpose. Regarding the relative amounts of the different forms of bark, we note that Ceylon returns show the following general percentages ranging over a period of four years: renewed, 30 per cent.; natural stem, 25 per cent.; root, 5 per cent.; branch, 40 per cent. Not much is to be learned from these figures, as they must, in the nature of the case, differ very widely according to the method of collection employed. As to composition, it was found that the branch bark (probably due partly to the quantity of wood which inevitably comes away with it) was but one-third as rich in quinine as the natural stem bark, while the renewed bark was twice as rich as the natural stem bark. The root bark was about equal to the natural stem bark. It is difficult to understand the last statement, in view of the well-known fact that an assay of the bark of stem and root of any one tree shows the latter to be much richer. The low result may have been due to the presence of wood, earth, or other foreign matter.

The methods of packing the bark have also undergone important modifications since the early days of cultivation. The extensive adulteration practised when the wild bark brought very high prices led to a demand for it in large pieces which could be readily and quickly examined; hence the appearance of the large *tabla* and *quill* forms, the latter afterwards becoming the standard for the cultivated bark. The bark of the trunk, and sometimes of the branches when very large, is cut into two-foot lengths, and each length removed in a single piece, which

in drying rolls up to form a quill. Such peeling can of course be successfully practised only at the appropriate season of the year. The bark of the roots, branches, and dead or dry trunks must be removed by chipping, scraping, or shaving, commonly the latter. The quills, after thorough drying, are carefully packed in bales, or preferably in boxes, to avoid breakage, and are marketed in packages of from 100 to 250 pounds. Large quantities of cultivated bark are still marketed in this way, but, increasing competition having lowered prices so that economy in freight has become a very important item, most of the bark is now broken up, and its bulk even reduced by high pressure.

The effect of cultivation upon the world's supply of Cinchona products has been revolutionary as regards quantity, quality, and price. Immense as was the area which yielded the original wild bark, it could never begin to furnish such extensive and regular supplies as are obtained at the present day. Various influences have combined to produce the improvement in quality. The first is the complete suppression of the very extensive adulterations and substitutions, some of them most difficult to detect, as well as very nearly that of the shipment of the lowest-grade barks. It does not pay to assume the risk of such undertakings, now that the expense is little, if any, less than that of supplying a good article. Again, the more strict selection of high-grade barks has resulted from the increasingly large demands of the quinine manufacturers, who appreciate the economy of obtaining 100 pounds of alkaloid from a ton of bark, instead of working over five tons to get the same quantity. Selection, however, is not the only means by which this end has been attained. The gardener's art has produced results which have entirely eclipsed the best efforts of nature. The mere transplantation and cultivation of the trees were early found to increase their richness in alkaloids. In Java, excellent results were obtained by grafting the young shoots of ledgeriana upon young plants belonging to a species of little value, as much as 13 per cent. of quinine sulphate being said to have been obtained from bark so produced. The careful production, selection, and propagation of hybrids have done more to increase the alkaloidal percentage than any other influence. Hybrids yielding from 11 to 13 per cent. of quinine sulphate were early produced, and very recently one has been reported from Java yielding no less than 16 per cent., equivalent to very nearly 12 per cent. of pure quinine. The effects of mossing have already been referred to. Samples of mossed bark yielding 8 per cent. and 10 per cent. of quinine have been of common occurrence. But it is not the occurrence of these exceptionally rich samples which marks the improvement in this direction; it is rather the increased average percentage of the annual yield. Unfortunately, we have no statistics enabling us to arrive at very definite conclusions as to the average percentages of the crops of original wild bark, but it is certainly not too much to say that a yield of quinine as great, say, as last year's average for the Java crop, would have been regarded as exceptional even for select lots of such wild bark. Within a few years large plantations in Java have been uprooted, because their yield of some 3 per cent. or more of quinine sulphate was seen to offer no hope of successful competition against the rich bark now coming on.

As to the relative richness of bark from different sections, we cannot believe that it has any permanent character, depending wholly upon methods of selection and cultivation. The cultivated barks of Bolivia originally took precedence, but superior cultivation in Asia has enabled plantations there to excel her in this direction, at least as regards select lots, which probably represent the general product of the future. For a long time the South American planters refused to resort to any special methods to increase the alkaloidal yield, such as were employed in India, but ruinous competition has compelled them to do so during recent years. The result, however, has not enabled them to hold their own in the market. In India the general average of the barks has tended in the direction of total alkaloids rather than of quinine, owing to the large production for the manufacture of febrifuge and the consequent cultivation of *C. succirubra*. At present a change to quinine-producing varieties is energetically under way. Ceylon has always been noted for the low grade of her barks, as regards either quinine or the total alkaloids. Upon the whole, Java bids fair to take the lead as to quality. The following estimate of quinine percentages was made concerning the crops of 1888 and 1889 by Messrs. Lewis and Peat:

	1889.	1888.		1889.	1888.
Ceylon crop	2¼ per cent.	2⅝ per cent.	Java crop	4 per cent.	4 per cent.
India "	2 "	2½ "	Bolivia crop	4½ "	4½ "

The Java crop of 1891 averaged 4·15 per cent.* for a crop of more than 8,500,000 pounds. This is probably not less than three times the average of the old wild crops of South America.

* Statistics of the Java crop of 1892 indicate an average of 4½ per cent.

The result does great credit to Java, for during the early history of her bark enterprise her plantations were found stocked with discouraging quantities of poor or even worthless barks, which have been eliminated by the most steady enterprise and patient industry.

The effect of this wonderful industry upon the price of bark, and especially upon that of quinine, can be appreciated by viewing the average prices per pound paid for all the bark imported into the United States in the several years between 1885 and 1890. It is to be noted that as the price thus steadily declined, the product steadily grew richer and more valuable.

Year	1885.	1886.	1887.	1888.	1889.	1890.	1891.	1892.	1893.	1894.	1895.	1896.	1897.	1898.
Price per lb. .	25·7c.	20·2c.	15·5c.	12·3c.	12·8c.	9·9c.	11·3c.	8·8c.	8·3c.	5·7c.	6·1c.	6·1c.	5·6c.	9·3c.

(Reported by McKesson and Robbins.)

The sudden fall in price about the year 1890 was attributed to the uprooting of the Ceylon plantations to make way for the more profitable industry of tea-growing, with the consequent flooding of the bark market. Before the effect of this influence had more than begun to pass away, the greatly increased production in Java depressed the price even more, and has kept it so until the past year (1898), when a decided improvement has occurred, as indicated in the above table.

Commercial History.

The above general history of Cinchona leaves little necessary to be said of its commercial history, except to deduce from the facts already presented certain practical conclusions showing the present conditions of supply and demand, these bearing especially upon our concluding remarks concerning pharmacognosy and classification.

For more than a century after Peruvian bark came into use, it was procured almost exclusively from the neighborhood of Loxa. In a memoir published in 1738, La Condamine speaks of the bark of Riobamba, Cuenca, Ayavaca, and Jaen de Bracomoros. Of these places, the first two, together with Loxa, lie within the ancient kingdom of Quito, at the southern extremity; the others are in the same vicinity, within the borders of Peru. The drug was shipped chiefly at Payta, whence it was carried to Spain and thence spread over Europe. Beyond the limits above mentioned the Cinchona was not supposed to exist, till, in the year 1753, a gentleman of Loxa discovered it, while on a journey to Santa Fé de Bogota, in numerous situations along his route, wherever, in fact, the elevation of the country was equal to that of Loxa, or about 6500 feet above the level of the sea. This discovery extended through Quito into Colombia, as far as two degrees and a half north of the equator. But no practical advantage was derived from it; and the information lay buried in the archives of the viceroyalty till subsequent events brought it to light. To Mutis has been awarded the credit of making known the existence of the Cinchona in Colombia, he having claimed its discovery in the neighborhood of Bogota in 1772. Recently great doubt has been thrown upon the justness of this claim. A botanical expedition was afterwards organized by the Spanish government, with the view of exploring this part of their dominions, and the direction was given to Mutis. Its researches eventuated in the discovery of several species of Cinchona in Colombia; and a commerce in the bark soon commenced, which was carried on through the ports of Carthagena and Santa Marta.

To these sources another was added about the same time (1776) by the discovery of the Cinchona in the centre of Peru, in the mountainous region about the city of Huanuco, which lies on the eastern declivity of the Andes, northeast of Lima, at least six degrees south of the province of Loxa. To explore this new locality, another botanical expedition was set on foot, at the head of which were Ruiz and Pavon, the distinguished authors of the *Flora Peruviana*. These botanists spent several years in that region, during which time they discovered numerous species. Lima became the entrepôt for the bark collected around Huanuco; and hence probably originated the name of Lima bark, so often conferred, in common language, not only upon the varieties received through that city, but also upon the medicine generally.

Soon after the last-mentioned discovery, two additional localities of the Cinchona were found; one at the northern extremity of the continent, near Santa Marta, the other very far to the south, in the provinces of La Paz and Cochabamba, then within the viceroyalty of Buenos Ayres, now in the republic of Bolivia. These latter places became the source of an abundant supply of excellent bark, which received the name of Calisaya. It was sent partly to the ports on the Pacific, partly to Buenos Ayres.

The consequence of these discoveries was a vast increase in the supply of bark, which was now shipped from the ports of Guayaquil, Payta, Lima, Arica, Buenos Ayres, Carthagena, and Santa Marta. At the same time the average quality was probably deteriorated; for, though

many of the new varieties were possessed of excellent properties, yet equal care in superintending the collection and assorting of the bark could scarcely be exercised in a field so much more extended. The varieties now poured into the market soon became so numerous as to burden the memory if not to defy the discrimination of the druggist; and the best pharmacologists found themselves at a loss to discover any permanent peculiarities which might serve as the basis of a proper and useful classification. The restrictions upon the commerce of South America, by directing the trade into irregular channels, had also a tendency to deteriorate the character of the drug. Little attention was paid to a proper assortment of the several varieties; and not only were the best barks mixed with those of inferior species and less careful preparation, but the products of other trees, bearing no resemblance to the Cinchona, were sometimes added, having been artificially prepared so as to deceive a careless observer. The markets of this country were peculiarly ill furnished. The supplies, being derived chiefly, by means of a contraband trade, from Carthagena and other ports on the Spanish Main, or indirectly through Havana, were necessarily of an inferior character; and most of the good bark which reached us was imported by our druggists from London, whither it was sent from Cadiz. A great change, however, in this respect took place after the ports on the Pacific were opened to our commerce. The best kinds of bark were thus rendered directly accessible to us: and the trash which formerly glutted our markets became in great measure excluded. Much bark was also imported from Carthagena and other ports of the Caribbean Sea, being brought down the Magdalena River from the mountains of Colombia; and an additional source of supply was opened through the Amazon, though this bark was of inferior quality. More or less perplexity attending the recognition of the barks continued until after the firm establishment of the bark culture and the cheapening of the price, to the exclusion of the worthless varieties, as already described.

The price of the bark was as irregular and uncertain as its quality. The Cinchona forests, being in thinly-inhabited districts, did not, for the most part, belong to individuals, but were open to the enterprise of all who chose to engage in the collection of the bark. As a consequence, the operations were carried on without reference to the future condition of the interest, and most wasteful modes of procedure resulted at length in the almost complete destruction of the source of supply, and in fabulous prices—$350 to $450 per cwt.—being paid for the better grades of bark. To this result private speculation, official intrigue, and national greed all contributed. Various attempts were made to utilize the leaves, flowers, and wood of the tree, but these were found not to contain the active constituents in sufficient amount. Fortunately, cultivation has about abolished all the evils and perplexities attending this trade, and has given us a steady and practically unlimited supply of the finest bark at prices which, compared with those above referred to, are merely nominal.* Although this great fall in price has resulted in a great financial depression at the present time, and has even brought disaster to some planters whose expenses have been greater than can be returned at present rates, yet, on the whole, the business has been very profitable, having paid for itself several times over. The present depression is supposed to have been brought on largely by the very heavy marketing by Ceylon, amounting, Ferguson says, to 82,000,000 pounds in seven years. Much of this marketing was in turn due to a craze for tea-planting, on account of which, from 1885 to 1888, 22,000 acres were uprooted, throwing upon the market 35,000,000 pounds of bark. Mr. A. C. Meyjes, who has devoted much study to the commercial history of Cinchona bark, estimated the annual consumption for 1894 at about 15,000,000 lbs.

One of the most important developments of the modern bark-trade is the fixing of the price in accordance with the quality as determined by assay. The most accurate method of selecting a characteristic sample for assay is a subject which has received much study, without the discovery of any method which does not depend for its value upon the discrimination and care exercised in its employment. The plan which is regarded as the safest is to take a given weight, say 8 ounces, from the inner portion of each package constituting the lot, mix and powder the entire suite, and furnish to applicants the required amount of the resulting powder. If any portion of any bale or bales is damaged, care is taken to add a proportionately large fragment of such portion. The bark is then recorded as containing so many units, a "unit" being each per cent. of quinine contained in a pound of bark. In rich bark the units are

* One writer, referring to the results of the Ceylon production, says, "We swamped the markets of the world, conferring simultaneously untold benefits on humanity by compelling a reduction in the price of Howard's quinine of more than 75 per cent. . . . Simultaneously we have reduced the value of the unit of quinine in bark against ourselves and all other producers from 2*s.* in 1880 to 3*d.*, and even 1½*d.*, though now 2*d.*"

worth more each than in poor, owing to the increased yield of alkaloid for the same cost of manufacture.

In the United States, at least, some difficulty has been experienced by druggists in securing the better grades of bark at regular rates, owing to the activity of the manufacturers in draining the market of the most desirable stock. The finer-appearing packages of unbroken bark, having been marketed at greater cost, are necessarily held at higher prices. Possessing no special value for manufacturing purposes, these fall to the share of the druggist, but at higher prices than broken bark of the same richness. This fact has led to the recognition of two distinct classes, known as manufacturers' bark and druggists' bark. While the latter is of finer appearance, it is not necessarily, nor in fact commonly, superior to the former. Indeed, not at all to the credit of our druggists, it is true that, because their bark is not commonly submitted to assay, they receive a bark of fine appearance but inferior quality. The greater portion of the bark is now sold at auction in the cities of Amsterdam and London.

Year	1887.	1888.	1889.	1890.	1891.	1892.
Packages of about 150 lbs. sold in London (mostly Ceylon and Indian)	90,435	90,470	70,635	67,528	53,850	56,833
Packages of about 150 lbs. held in London at close of year	59,619	56,754	57,181	48,213	49,142	37,878
Packages of about 180 lbs. sold in Amsterdam (mostly Java)			24,749	39,636	42,520	45,239

Stocks ordinarily held in Amsterdam are very much smaller than those in London.

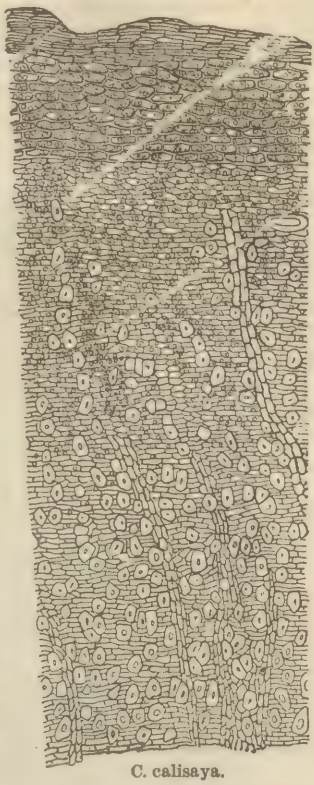
Besides this, a considerable amount of Bolivian bark goes to Hamburg and to Havre, whence the Paris market is partly supplied. New York receives little bark direct, the most of it being purchased in London and Amsterdam. Samples of the various lots are forwarded in time for a selection to be made and purchases ordered by mail or cable. From the statistics which we have given, showing the character of the bark produced by the several countries, and also the sources of the bark sold in the principal markets, those interested can readily judge as to the general character of the offerings at different points.

A few words remain to be said of the wild South American barks at present dealt in, and only partly included in the preceding enumeration. Enough has already been said to explain their very general exclusion. At the same time it is to be remembered that there still remain in the London warehouses some 1500 tons of such bark, collected many years ago, which is being gradually worked off upon the market at very low prices. Another portion of such bark is even yet being collected, and, as much of this latter is used by retail druggists, it demands our attention. This bark is almost wholly of two sorts, (1) the Crown bark,—Cuenca, Loxa, and Huanuco,—from *C. officinalis*, and (2) the Hard Yellow or Maracaibo variety. Concerning the former it is exceedingly difficult to obtain statistics, but the annual production is supposed to be about 1200 packages. The greater portion of it goes to France, and is probably consumed in the southern European countries. Of the 57 packages of bark imported into the United States direct from South America in 1891, 27 were of the cultivated Calisaya and the remainder Crown. This is a fairly good bark. Of the second, or Maracaibo, there is no very regular collection and shipment. The most of it goes to Hamburg, and there large quantities of it can be obtained at any time. Considerable of it goes to London also, and once in several years the United States receives a shipment of several hundred bales. The most of this is reshipped to the West Indies or goes to the Pacific coast, and it is mostly used in making Huxham's tincture and other preparations in which the bitter element is the chief consideration. Although really very poor, it is, after sifting and winnowing, a fine-looking yellow bark and quite bitter, owing to alkaloids other than quinine, and it finds a ready sale at fair prices. It may be added that occasional packages of wild Calisaya in table form, and of wild thick Red bark, are received in London.

Classification.

Reference has already been made to the extreme difficulty which attended the earlier attempts to classify the Cinchona barks of commerce,—difficulties not probably encountered elsewhere in the Materia Medica. We have also made it clear that these difficulties no longer exist, the varieties having been reduced to a very few. Most of the discarded barks will be found described in previous editions of this work. We find it necessary to enumerate and describe here only the Pale bark, from *C. officinalis*, the Red bark, from *C. succirubra*, the Yellow bark, from *C. calisaya* and its var. *ledgeriana*, and the Hard Yellow or Maracaibo bark, and to refer briefly to the hybrid forms. First, a few words concerning the forms in which Cinchona bark occurs. We have (1) the large flat pieces or chips of irregular shape and size,—this referring at present almost wholly to the Maracaibo variety; (2) the small chips or broken bark, referring in large part to the root bark, and to other bark broken for close packing; (3)

the shaved bark, referring to some root bark and to stem bark taken from dry stems, but chiefly to branch bark; (4) the quill bark, referring to natural bark taken from the stem and root in quill form, this including the uncultivated pale bark and all the varieties of cultivated bark; and (5) the renewed and mossed bark, which may be of any cultivated variety. The classification of all varieties and forms into druggists' and manufacturers' barks enables us to dispense in great part with a description of some of these forms. The manufacturer cares nothing for form, appearance, or structure, and but little for the variety of his supplies. He is interested wholly in its composition, and this he determines by assay. For this reason most of the broken bark goes to him. The druggist requires the quill or large chip bark: so that the great bulk of the branch bark is also thrown, at low prices, upon the hands of the manufacturer.



As regards the root barks, no classified description has come to the writer's attention. In their structure they correspond very closely to the stem barks of the same variety. They can be readily distinguished from the latter by their less thickness, lighter external and darker inner color, greater softness, and twisted or contorted structure. They occur in short, irregular quills or chips, or sometimes as shavings, and contain very much more dust than any other form. Except partly as regards structure, the descriptions of stem barks will not apply to branch barks of the same variety, for the characteristic markings do not appear in the young condition. The branch bark appears in shavings, to the inner surface of many of which more or less of the wood adheres. If the branches were shaved while yet fresh, these shavings will be more or less rolled up and curled; but if dry before being removed, this rolling and curling will not occur. Shaved bark taken from living trees is thin, soft, and brittle, consisting of the outer bark only. The large quills are of uniform length from the same plantation, but not necessarily so from different plantations or different sections. They are commonly from 2 to 3 feet in length, but some have been marketed having a length of 5 feet. Usually they represent the entire circumference of the stem, but occasionally only half of it. In drying they roll up very tightly from one or both edges, and rarely one will be wholly or partly involved in another. The periderm, with all its markings, remains intact, and no other form so well displays the natural appearances as this. Mossed bark differs from natural stem bark in its great thickness and weight, less breadth of the quills, freedom from lichens, very dark color, and rough, corrugated or warty surface. The outer bark or cellular portion bears a greater ratio to the inner or fibrous portion than in natural bark. Renewed bark is lighter, both in color and weight, thinner, soft and brittle, and marked by a very peculiar external smoothness, sometimes very marked indeed. In its general appearance it is strikingly like a root bark, except for the relative straightness of its fibres. Like the mossed bark, it is in narrow, only partly rolled quills or bands, and is entirely free from lichens.

As they differ so greatly among themselves in coloration, lichen-growth, degree and form of exfoliation, structure and consequent fracture, there are but few characters which can be combined in a general description of the Cinchona barks which we consider. The external color varies from light ashy gray to nearly black, the inner varies less in its shades of yellow-brown and red-brown. All are more or less bitter, and most are astringent, but only Loxa bark has a distinctive odor. The fracture is never very long-splintery, and never tough. As to structure, the bast fibres are loosely arranged, the radial rows being neither continuous nor very long. The fibres themselves are always unbranched, which distinguishes the true from the false barks, are rather short and obtuse, brittle, and usually easily detached from their bed. Laticiferous ducts and stone-cells may or may not be present. The former become less conspicuous as the bark grows older, so that their relative absence becomes indicative of a stage in which the due proportion of alkaloid should have been acquired.

It may be noted here that by far the greater portion of the alkaloid, particularly quinine, is stored in the outer bark, though that in the inner bark is in a purer state. The latter is not stored in the fibres, but in the cellular tissue between them.

As regards the former classification of barks by color, it referred only in small part to the external color, chiefly to the powder. These colors were never regarded as absolutely characteristic, as the three barks, yellow, red, and pale, exhibited gradations by which they mingled at their extremes. Under present conditions, the lines of demarcation have become even more indistinct, and, as a matter of fact, in the market the terms "yellow" and "red" are used with great looseness. It is true that we receive much pure-blooded Yellow Bark, *Ledgeriana* from the East, and *Calisaya* both from there and from South America; but it is also undeniable that much of the bark sold under the several names is of mixed blood, and the typical char-

acters are often greatly obscured. The presence in our market of these mixed forms has made the terms even less valuable than they once were, and dealers cannot be found to agree as to the character of many samples. Nevertheless, the occurrence of the typical forms, and the appearance in a hybrid of the blended characters, render it desirable to preserve this classification, and to group the new forms around the types.

C. calisaya.

Yellow or Calisaya Bark. Cinchona Flava.*

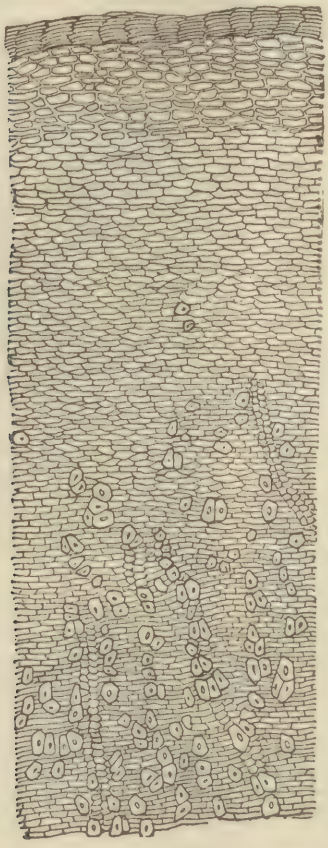
Derived from *C. calisaya* and its var. *ledgeriana*. Scarcely collected in a wild state, but cultivated in all plantations. Demand and production rapidly increasing. The largest quinine yielder, its amount being 70 to 80 per cent. of the total alkaloid. The var. *ledgeriana* yields a very valuable hybrid bark with *C. succirubra*. *C. calisaya* also hybridizes with the latter species.

Description. Flat or "table" bark, now very little produced. Quills, unless broken for shipment, large and handsome, 1½ to 2½ feet long, single or double, sometimes as much as 2½ inches in diameter, ⅛ to nearly ¼ inch thick. Externally gray to lightly brownish gray, internally light cinnamon-color, the striæ very fine. Powder light yellowish brown. Its lichens are thin and closely adherent, not rendering it shaggy. External markings very characteristic, consisting of a very light longitudinal ridging or none at all, but of numerous transverse and longitudinal fissures or cracks, the presence and arrangement of which constitute the chief characteristic of Calisaya. Upon the young stems and branches they do not appear. The first to appear are the usually large primary fissures, which encircle the stem at the nodes, or points where pairs of leaves once stood. Subsequently, numerous smaller secondary transverse fissures appear upon the internodes, and these quickly become connected and crossed by longitudinal cracks, thus dividing the periderm up into more or less quadrangular checks, which may remain attached or fall away. This gives to mature Calisaya bark an appearance of scaliness like that upon the tarsus of a fowl, and this is known to the South American collectors by a term which signifies the "chicken-leg appearance." It has also been spoken of as a "carving-like" marking. Like the roughness upon a musk-melon, its great development is regarded as an indication of high quality, and especially is this true of a close proximity of the primary fissures. This roughness is also regarded as a sure indication of maturity. There are excellent distinctions between these and the somewhat similar fissures upon the bark of *C. officinalis*. In the latter they are coarser and more gaping. Even more important is the absence from Pale Bark of most of the longitudinal cracks, so that it does not become "chicken-legged," or at most only very slightly so. The external color of Yellow Bark is lighter than that of the Pale Bark. Longitudinal ridges are few if any, short, irregular, and inconspicuous. In fine South American bark some very small bright-red spots can be detected upon the periderm. East Indian Calisaya can commonly be recognized by its somewhat dingy or brownish shade of gray, the gray of the South American bark being bright and somewhat bluish-steel-colored.

In structure, the zone of large, rather numerous laticiferous ducts just outside the bast is conspicuous in young, and therefore inferior, samples. The rather small bast fibres are loosely scattered, almost uniformly single, a radial arrangement being made out. The fracture is rough-splintery, though not coarse. Stone-cells few or none. Odorless, more bitter, and less astringent than the Pale Bark. Ledger bark is the same as Calisaya in all its essential characters, but does not reach so great a size. In hybrids of Calisaya with Succirubra the characters and quality of the latter appear to predominate.

Red Bark. Cinchona Rubra.†

Derived from *C. succirubra*. Scarcely collected in a wild state, but cultivated in all plantations except those of South America. Demand and production rapidly decreasing. A large



* This is the bark which is recognized under the name of Cinchona by the U. S. Pharmacopœia (see p. 388), in which it is officially described as follows: "In quills or incurved pieces, varying in length, and usually two or three, or sometimes five Mm. thick; the outer surface covered with a gray or brownish-gray cork, usually slightly wrinkled, marked with transverse and also with intersecting longitudinal fissures (*C. Calisaya*), and sometimes with scattered warts and slight longitudinal ridges; inner surface light cinnamon-brown, very finely striate; fracture short and granular in the outer layer, and finely fibrous in the inner layer; powder light brown or yellowish brown; odor slight, somewhat aromatic; taste bitter and somewhat astringent."

† This is the bark which is recognized by the Br. Pharmacopœia (see p. 388), officially described as follows: "Imported in quilled or more or less incurved pieces, coated with the periderm, and varying in length from two inches to a foot (five to thirty centimetres) or more—the bark itself from about one-tenth to a quarter of an inch (two and a half to six millimetres) thick, or rarely more; outer surface brownish or reddish brown in color, more or less rough from longitudinal ridges which are most apparent in the branch bark, with numerous warts often running into lines in the larger pieces; in some varieties marked with numerous transverse cracks which have not thickened edges; inner surface brick-red or deep reddish brown, irregularly and coarsely striated; fracture shortly fibrous in the smaller, and finely fibrous in the larger, pieces; powder brownish or reddish brown; no marked odor; taste bitter and somewhat astringent."

alkaloid yielder, but of this only about 20 per cent. is quinine. Largely hybridized with *C. officinalis.* Also hybridized with *C. calisaya* and its var. *ledgeriana.*

Description. Quills similar to those of Calisaya, though running somewhat broader and thicker. Externally of a dingy brown gray, less lichen-bearing than either of the others. Inner surface of a more reddish cinnamon-brown than in Calisaya. Powder reddish brown. The important characteristic of red bark is the prominent longitudinal ridges, many of them short and confluent, with intervening furrows or elongated meshes. The ridges are suberous, bear numerous small warty protuberances, and may be traversed by faint cracks. Transverse fissures may or may not be present in red bark. If so, they are few, short, and irregularly disposed, and not connected by longitudinal cracks to give the checkered appearance of Calisaya. Hybrids with officinalis display numerous transverse fissures, and the external color is lighter and more dingy. Fracture short-splintery, not coarse. Odor none. Taste bitter and astringent.

Structure. Bast fibres few and loosely disposed in numerous interrupted, single or double radial lines, much disposed to stand in pairs or in threes. Laticiferous ducts more disposed to remain conspicuous than in the other barks, large, few, and distinct in a single row near the bast region. Stone-cells wanting.

C. succirubra.

Pale Bark.

Varieties and Synonymes. Crown Bark, Loxa or Loja Bark, Cuenca Bark, Huanuco Bark. Derived from *C. officinalis.* Collected in a wild state about Loxa and other parts of Ecuador, and cultivated in all plantations except the South American, especially in

C. officinalis. (A rather young sample.)

India. Demand and production decreasing. Quinine constitutes 60 to 70 per cent. of the total alkaloids. Largely hybridized with *C. succirubra.*

Description. Quills single or double, irregularly broken or entire, 3 or 4 to 15 or 18 inches long by ¼ to ⅜, rarely 1, inch in diameter, and having a very wide range in thickness, the natural mostly 1 to 2 lines thick. Shaggy, with more abundant lichens than in any other species, the abundance of these having been considered, not entirely without reason, as an indication of the relative quality. Color of periderm darker than in the other species, but varying much from a brown gray to nearly black. Inner surface of a paler brown than in the other species, finely striate. Powder pale brown. The external markings consist of transverse fissures and longitudinal ridges, some of them wart-bearing. It is only in the thinner samples, in which the warts and fissures scarcely appear, that the ridges are continuous and conspicuous. In the prominence and breadth of its fissures and the inconspicuousness of its ridges, this bark is most distinct from the Red Bark. These characters are yet sufficiently distinct from the somewhat similar ones of Calisaya, as noted in describing that bark.

Fracture short, the inner fibrous zone sharp and narrow. Taste not so bitter as in the others. Odor of the genuine Loxa variety peculiar and characteristic. Its structure shows the rather short and not numerous bast fibres in short interrupted single or double radial rows, and much disposed to occur in bundles of three to six or more. Stone-cells rarely seen, and laticiferous ducts conspicuous only when young.

Hard Yellow, or Maracaibo Bark. Puerto Cabello Bark.

Derivation not at all certain. Collected only in a wild state in the mountains of Southern Colombia, and yielding almost the whole of the inferior wild bark now collected for market. Importation and sale in the United States quite irregular and unimportant. One of the best of the lower-grade barks, but not to be compared with any of those already described. Said to yield about 2 per cent. of crystallizable sulphates, three-fourths of which is quinine sulphate, but a characteristic specimen assayed for this investigation by Prof. Virgil Coblentz yielded 2·65 per cent. of total alkaloids, only a trace of which was quinine. Contains a large amount of resin. The common or commercial names by which have been designated the several barks of the northern countries related to this one are of very irregular application. At the time when the trade in them was large and important, the term "Maracaibo Bark" was restricted to the less resinous variety, derived from *C. cordifolia*. At the present time, however, it is commonly applied in the New York and London markets to the variety under consideration. It is also often sold simply as "Yellow Bark," and it is not impossible that it is sometimes accepted, under this synonyme, for Calisaya.*

Description. In irregular broken pieces, rarely so short as an inch, and mostly from 2 to 5 or 6 inches long, 1 to 2½ or 3 inches broad, and ⅛ to ⅜ of an inch thick. Formerly it included many much smaller fragments as well as much dust, but these portions are now mostly sifted and winnowed out before marketing. The pieces are more or less flat, the thinner and narrower ones somewhat incurved, the broader and thicker recurved. The bark is compact, heavy, and fibrous. Most of the pieces display upon the outer surface more or less of the periderm, forming silvery-white or yellowish-white patches, very thin and rather soft. Occasionally the periderm is instead dark, hard, very rough, and much fissured. From many pieces the entire periderm is absent, disclosing the outer face of the bast, very similar to the inner face. This is compactly and rather finely fibrous, of a deep yellow, with a slight rust-brown tinge. Throughout, the bast is of this structure and color. Between it and the periderm there may be seen with varying distinctness, in most pieces, a characteristic resinous band of irregular width, dark reddish brown and waxy-lustrous on the cut surface. The radial rows of bast fibres are quite irregular. The fracture is quite long-fibrous. The odor is distinct, and the taste quite bitter.

H. H. Rusby.

* False Barks. In the sixteenth edition of the U. S. Dispensatory may be found an elaborate description of the various false barks which have from time to time entered commerce. Most of this we omit, but the so-called Cuprea Barks at one time were of so much importance that we here insert the matter contained in that edition concerning them. It may be stated, however, that no considerable collection of these barks has been made for some years, and that it does not seem probable that they will ever again enter commerce. Some fifteen hundred tons of them are said, however, to be still stored in London, the remnant of a much larger quantity of the barks which has been and still is being slowly sold off for unprofessional uses.

Cuprea Bark. As early as 1820, a Brazilian surgeon, by the name of Remijio, pointed out to his countrymen that the bark of certain small trees or shrubs growing in Brazil was as effective as the Peruvian bark in malarial fevers, and ever since in Brazil these plants have been known by the name of *Quinia de Sera*, or *Quinia de Remijio*. St.-Hilaire (*Plantes Us. Bras.*) placed these shrubs in the genus Cinchona, as *C. Remijiana, ferruginea*, and *Vellozii*; but De Candolle (*Prodromus*, iv. 357) erected for them a new genus, Remijia, which has since been universally recognized by botanists. It is distinguished from Cinchona by the fruit capsules opening semi-loculicidally, by its peltate seeds, and by its inflorescence in elongated axillary racemes with opposite fascicles of flowers. In 1857 a new bark appeared in the London market, but only within the last few years has this so-called *Cuprea bark* appeared in large quantities. After its value became known, the search for it in South America became very active; indeed, in Colombia a "fever" is said to have broken out, which has caused agriculture to be neglected and deranged the business of the country, whilst in London the supply has been so great as to break the whole cinchona market. Mr. S. G. Rosengarten informs us that the bark reaches this country from London, and also directly from Colombia. There are two distinct regions which yield it: one is the lower part of the basin of the Magdalena River, in the province of Santander, the trees growing in the mountain-chain of La Paz, and the port of export being Bucaramanga; the other the basin of the Orinoco, among the mountains which constitute the eastern branch of the Cordillera of the Andes.

Bentham states that the genus Remijia comprises 13 species: according to the researches of José Triana, but two of these, *R. Purdieana*, Wedd. (*Ann. Sci. Nat.*, 3e sér., xi. p. 272), and *R. pedunculata*, Triana (*Cinchona pedunculata*, Karsten), yield the Cuprea bark of commerce. (*P. J. Tr.*, April, 1882.) An exceedingly important fact connected with these trees is that they grow in a dry climate, and in position a little above the level of the sea, and hence without doubt could be cultivated in many intertropical countries where the Cinchonas will not grow. They would in all probability flourish within the limits of the United States.

The specimens of Cuprea bark which have been furnished us as typical by the Messrs. Rosengarten are composed of pieces varying from half an inch to 3 or 4 inches in length, from a quarter to a twelfth of an inch in thickness, strong and hard, varying from a yellowish to a red cinnamon color, and having a somewhat cupreous tint, distinctly curled, *very smooth* upon their inner surface, on their outer surface smoothish, or in the larger specimens rough, with the epidermis usually adherent; marked, except in the very large pieces, with fine wrinkles, and sometimes with transverse or spiral grooves, which are sometimes quite shallow, but often are deeply and sharply cut. The texture is dense and hard, the fracture is short, not fibrous, and free from spicules. The microscopic characters differ from those of the true Cinchonas in the bast-cells being small and with their cavity widely open, not obliterated by secondary layers. The shaved transverse section of Cuprea bark is further characterized by a peculiar horny appearance different from that of the true Cinchonas. The bark is also remarkable for its density, which Arnaud gives as from 1·128 to 1·18, and consequently sinks in water. Cuprea bark varies in the percentage of quinine it contains. The Messrs. Rosengarten state that the yield in their laboratories has been from 1 to 2 per cent., and that usually the bark

Chemical History.

In the analysis of Cinchona bark, the attention of chemists was at first directed exclusively to the action of water and alcohol upon it, and to the determination of the relative proportions of its gummy or extractive and resinous matter. The presence of tannin and of various alkaline or earthy salts in minute quantities was afterwards demonstrated. Fourcroy made an elaborate analysis, which proved the existence of other principles in the bark besides those previously ascertained. Dr. Westring was the first who attempted the discovery of an active principle in the bark, on which its febrifuge virtues might depend; but he was not successful. Seguin afterwards pursued the same track, and endeavored, by observing the effects of various reagents, to discover the relative value of different varieties of the drug; but his conclusions have not been supported by subsequent experiment. M. Deschamps, an apothecary of Lyons, obtained from bark a crystallizable salt of lime, the acid of which Vauquelin afterwards separated, and called *kinic acid* (*quinic acid*). The latter chemist also pushed to a much greater extent the researches of Seguin as to the influence of reagents, and arrived at the conclusion that those barks were most efficient which gave precipitates with tannin or the infusion of galls. Reuss, of Moscow, succeeded in isolating a peculiar coloring matter from red bark, which he designated by the name of *cinchonic red*, and obtained a bitter substance which probably consisted in part of the peculiar alkaline principles subsequently discovered. The first step, however, towards the discovery of cinchonine and quinine* appears to have been taken by the late Dr. Duncan, of Edinburgh, so early as 1803. He believed the precipitate afforded by the infusion of cinchona with that of galls to be a peculiar vegetable principle, and accordingly denominated it *cinchonin*. Dr. Gomez, a Portuguese physician, convinced that the active principle of bark resided in this cinchonin, but mixed with impurities, instituted experiments upon some pale bark, which resulted in the separation of a white crystalline substance, considered by him to be the pure *cinchonin* of Dr. Duncan. It was obtained by the action of potassa upon an aqueous infusion of the alcoholic extract of the bark, and was undoubtedly the principle now universally known by the name of *cinchonine* or *cinchonia*. But Dr. Gomez was ignorant of its precise nature, considering it to be analogous to resin. M. Laubert afterwards obtained the same principle by a different process, and described it under the name of *white matter*, or *pure white resin*. To Pelletier and Caventou was reserved the honor of crowning all these experiments, and applying the results which they obtained to important practical purposes. In 1820 they demonstrated the alkaline character of the principle discovered by Gomez and Laubert, and gave it definitively the name of *cinchonine*. They discovered in the yellow or Calisaya bark another alkaline principle, which they denominated *quinine*. Both these bases they proved to exist in the barks, combined with *quinic* or *kinic acid*, in the state of *cinchonine and quinine quinate*. It was, moreover, established by their labors that the febrifuge property of bark depends upon the presence of these two principles. In 1833, MM. O. Henry and Delondre discovered a new alkaloid, but afterwards, finding its composition in its anhydrous state the same as that of quinine, concluded that it was a hydrate of that base. About 1844, Winckler announced anew the existence of the same principle, which he considered distinct, and named *chinidine;* and, under the similar title of *quinidine*, it has now taken its place among the cinchona alkaloids. In 1853, M. Pasteur found that what had been considered as quinidine consisted in fact of two alkaloids, for one of which he retained the name of quinidine, and called the other *cinchonidine;* and, on pushing his investigations further, he ascertained that no less than six alkaloids may be obtained from different varieties of Peruvian bark,—namely, *quinine* and *quinidine* isomeric with each other, *cinchonine* and *cinchonidine* also isomeric, and two others, derivatives from the preceding through the agency of heat, viz., *quinicine* from quinine, and *cinchonicine* from cinchonine, each being isomeric with the alkaloid from which it is derived.†

is remarkably free from inferior alkaloids. The complete absence of cinchonidine is said to be characteristic of them. Messrs. D. Howard and I. Hodgkin, Dr. B. H. Paul, and Mr. Cownley and Mr. T. G. Whiffen almost simultaneously announced the discovery of a new alkaloid, *homoquinine* or *ultraquinine*, which there is some reason for believing is a double salt of quinine and quinidine. (*Chem. News*, xlv. 6.) The characteristic chemical product is the alkaloid *cinchonamine*, whose right to a separate existence seems to be well established.

* The termination *a* or *ia* was adopted by the American and English chemists to distinguish the organic alkaloids from other organic proximate principles the names of which terminate in *in* or *ine*, the terms quinine and cinchonine becoming *quinia* and *cinchonia*. On the same principle, *quinidine*, *quinicine*, *cinchonidine*, and *cinchonicine* were called respectively *quinidia*, *quinicia*, *cinchonidia*, and *cinchonicia*. The Committee of Revision of the Pharmacopœia, 1880, however, finally accepted the custom of Continental writers, and the *a* and *ia* termination was dropped and *ine* substituted.

† It is unfortunate that in Germany some confusion yet exists in the names adopted for the cinchona alkaloids. Cinchonidine is frequently called *chinidine*, and Hesse insists on calling quinidine *conchinine*.

The following table of the natural Cinchona bases is given by A. H. Allen on the authority of Messrs. Paul and Cownley. In it the alkaloids are arranged according to formulas:

Alkaloid.	Formula.	Melting Point °C.	Optical Rotation, SD.[1]	Chief Source.
I. *Cinchonine Class:*				
Paricine	$C_{16}H_{18}N_2O$	130	0	*C. lutea* and *C. succirubra* from Darjeeling.
Cinchotine,	$C_{19}H_{24}N_2O$	277	+	Crude cinchonine sulphate.
Cinchonamine,		194	+121·1	*Remijia Purdieana.*
Hydrocinchonine,		256	. .	*C. cuprea.*
Hydrocinchonidine (Cinchamidine),		229	−98·4	Mother-liquors of homocinchonidine.
Cinchonine,	$C_{19}H_{22}N_2O$	255	+226·5	Various species of *cinchona.* Almost always present.
Cinchonidine,		202	−70	Especially *C. rubra.*
Homocinchonidine,		207	−107	With cinchonidine.
Cinchonicine,		50	+20·1	By heating cinchonine.
Paytine,	$C_{21}H_{24}N_2O$	156	−49·5	From white bark of Payta.
Paytamine,		. .	. .	
II. *Quinamine Class:*				
Quinamine,	$C_{19}H_{24}N_2O_2$	172	+104·5	*C. succirubra* from British India and Java.
Conquinamine,		121	+204·6	*C. officinalis, C. calisaya.*
Javanine	. . . . .	. .	. .	*C. calisaya* from Java.
Cupreine	$C_{19}H_{22}N_2O_2$	198	−175·3	*C. cuprea* or *Remijia pedunculata.*
III. *Quinine Class:*				
Hydroquinine,	$C_{20}H_{26}N_2O_2$	168	−142·2	In mother-liquors from quinine sulphate.
Hydroquinidine,		166	+	
Quinine,	$C_{20}H_{24}N_2O_2$	172	−145·2	Calisaya officinalis, etc.
Quinidine,		168	+236·8	
Quinicine,		60	+44	By heating quinine sulphate.
IV. *Cusconine Class:*				
Chairamine,	$C_{22}H_{26}N_2O_4$	233	+100	*Remijia Purdieana* (Cusco or False Cuprea Bark).
Conchairamine,		120	+68·4	
Chairamidine,		127	+7·3	
Conchairamidine,		114	−60	
Concusconine,		144	+40·8	
Aricine	$C_{23}H_{28}N_2O_4$	188	−58·2	
Cusconine,	$C_{23}H_{28}N_2O_4$	110	−54·3	
Cusconidine,		. .	. .	
Cuscamine,	. . . . .	218	. .	*C. Pelletierana.*
Cuscamidine,		. .	. .	
V. *Anhydro-bases:*				
Dicinchonicine	$C_{38}H_{44}N_4O_2$	40	+66	*C. rosulenta* and *C. succirubra.*
Diquinicine	$C_{40}H_{46}N_4O_3$	. .	+	*C. rosulenta* and "quinoidine."

The values for specific rotatory power refer to solutions of the free alkaloids in nearly absolute alcohol.

Besides these natural bases we have a number of alkaloids formed by the alteration or treatment of these natural bases, or in some cases molecular compounds of two of the natural bases. They will be noted later in the description of individual bases.

Chinoidine or *Quinoidine* is a term now applied to the resinous substance consisting not only of the *amorphous* natural alkaloids, but of those which are produced artificially through the action of heat and acids upon the crystalline alkaloids. It was formerly official, but was dropped at the 1890 revision. The other constituents of Cinchona bark are *Quinic* or *Kinic*, *Quinovic* or *Kinovic*, *Quinotannic* or *Cinchotannic* acids, *Quinovin* or *Kinovin*, *Cinchonic red*, volatile butyraceous oil in small quantity, red and yellow coloring matter. These constituents will now be considered in detail.

Quinine, *Quinidine*, *Cinchonine*, *Cinchonidine*, or their sulphates, having been made official, will be treated of under separate heads (see Index). *Quinicine* and *Cinchonicine*, being derivatives of quinine and cinchonine, will be considered under their respective sources.

QUINAMINE, *Quinamia*, $C_{19}H_{24}N_2O_2$. Dr. O. Hesse discovered this cinchona alkaloid in the bark of *C. succirubra* from Darjeeling in 1872. He has since found it in all the East Indian succirubra barks, as well as in the barks of *C. nitida*, *C. calisaya*, var. *Schuhkrafft*, *C. erythrantha*, *C. erythroderma*, *C. rosulenta*, and *C. calisaya* (Para bark), and particularly in *C. ledgeriana*. De Vrij (*L'Union Pharm.*, 1877, p. 204; *N. R.*, 1877, p. 300) has published a process for its preparation. It crystallizes in very long, asbestos-like, white prisms, without water of crystallization. It is nearly insoluble in cold water and in solution of potassa or am-

monia, more easily in boiling water; is readily dissolved by hot alcohol, which deposits it in crystals, and less readily by diluted alcohol. Ether, benzin, and benzene dissolve it rather easily at ordinary temperature, more readily when boiling hot, and give it up crystallized on cooling and evaporation. In alcoholic solution it has an alkaline reaction. It neutralizes sulphuric and hydrochloric acids, forming with the latter an amorphous salt, but with the former one that crystallizes with difficulty in hexagonal scales and short prisms. Its solution is dextrogyrate. Quinamine is almost tasteless, but its solutions in acid are very bitter. Unlike quinine, its sulphuric acid solution is not fluorescent. Its reaction with gold chloride is very characteristic, the solution of the chloride producing with it a yellowish-white precipitate, which soon becomes purple, and separates gold, the supernatant liquid assuming a purplish-red and afterwards a brown color. (For other characters, see *A. J. P.*, 1872, p. 302.)

Quinamidine, *Quinidamia* (*Conchinamine of Hesse*), $C_{19}H_{24}N_2O_2$, is found in *C. rosulenta* and *C. succirubra*, and probably exists in other species of red bark. It crystallizes in long, brilliant prisms, which melt at 123° C. (253·4° F.). A crystalline hydriodide has been produced. Like quinamine, its gold salt soon decomposes.

Cupreine, $C_{19}H_{22}N_2O_2$, was discovered by Paul and Cownley in the bark of *Cinchona cuprea*, or *Remijia pedunculata*, on the upper Orinoco. It crystallizes from alcohol in anhydrous form, but from ether in prisms with $2H_2O$. Cupreine is sparingly soluble in ether or chloroform, but readily soluble in alcohol. This solution is lævogyrate, alkaline, gives a dark reddish-brown color with ferric chloride, and responds to the thalleioquin test. It forms with soda a definite crystallizable compound containing $C_{19}H_{21}N_2O.ONa$, from the solution of which the alkaloid cannot be extracted by ether. This cupreine-soda is important as furnishing a synthesis of quinine, according to the reaction $C_{19}H_{21}N_2O.ONa + CH_3I = C_{20}H_{24}N_2O_2 + NaI$. (See *Cuprea Bark*, p. 403.)

Homoquinine, $C_{19}H_{22}N_2O_2$, was discovered in 1881 simultaneously by D. Howard and J. Hodgkin, B. H. Paul, A. J. Cownley, and T. G. Whiffen (*P. J. Tr.*, 1881, p. 497; 1882, p. 905). It was first noticed by Paul and Cownley on account of the readiness with which it crystallized from its ethereal solution, and is now recognized as a molecular compound of quinine and cupreine of the formula $C_{20}H_{24}N_2O_2,C_{19}H_{22}N_2O_2+4H_2O$, and can be obtained by precipitating a solution of sodium cupreinate with one of quinine hydrochloride. It can be resolved into its constituent parts by precipitating the solution with solution of caustic soda, when the quinine may be shaken out with ether, while the cupreine remains in the alkaline liquid as sodium cupreinate. It is freely soluble in alcohol and chloroform, sparingly in ether, from which it crystallizes in proportion as it can take up water. (Hesse.) It is also soluble in diluted sulphuric acid, producing fluorescence, and gives with chlorine water and ammonia a green coloration (thalleioquin). The sulphate coincides exactly in properties with quinine sulphate, except in its behavior with ether. Its tartrate closely resembles cinchonidine tartrate. Homoquinine and its salts behave towards polarized light like quinine.

Hydroquinine, $C_{20}H_{26}N_2O_2$, was discovered by Hesse in the mother-liquors from which quinine sulphate has been crystallized; he afterwards found it in the commercial quinine salt to the extent of 4 per cent. Quinine cannot be perfectly freed from hydroquinine even by repeated crystallization of the neutral sulphates, but the hydroquinine can be completely separated by converting the alkaloid into the acid sulphate and recrystallizing this from water or alcohol, when the hydroquinine remains in the mother-liquor. (*Allen.*) According to Hesse, it dissolves freely in alcohol and ether, and gives the thalleioquin reaction with chlorine water and ammonia like quinine. (*P. J. Tr.*, 1882, p. 904.)

Hydroquinidine (hydroconchinine), $C_{20}H_{26}N_2O_2 + 2\frac{1}{2}H_2O$, is crystalline, dissolving freely in hot alcohol and in chloroform, but less freely in ether. It gives the thalleioquin reaction like quinine. (*P. J. Tr.*, 1882, p. 904.)

Hydrocinchonidine, $C_{19}H_{24}N_2O$, bears the same relation to cinchonidine that hydroquinine does to quinine. It is found associated with homocinchonidine in commercial cinchonidine. (*A. J. P.*, 1883, p. 20.)

Cinchonamine, $C_{19}H_{24}N_2O$. This alkaloid was discovered in 1881 by M. Arnaud in Cuprea bark. It exists in the proportion of 0·2 per cent., and is usually associated with cinchonine. His process is to treat the bark with milk of lime, dry the mixture, exhaust with boiling alcohol, distil off the alcohol, and take up the residue with diluted hydrochloric acid; cinchonamine hydrochlorate crystallizes out, cinchonine hydrochlorate remaining in solution. Cinchonamine is insoluble in cold water, soluble in 30 parts of alcohol, more soluble in hot alcohol, and in 100 parts of ether. It is dextrogyrate. For formulas for salts of cinchonamine, see

A. J. P., 1884, 156. Physiologically, cinchonamine, according to the experiments of Sée and Bochefontaine, has six times the toxic power of quinine, and has decided sialagogue properties. (*P. J. Tr.*, 1885, 791.) *Cinchotine*, $C_{19}H_{24}N_2O$, is isomeric with cinchonamine; it dissolves very sparingly in ether.

PAYTINE, $C_{21}H_{24}N_2O.H_2O$, was discovered by Hesse in the white Payta bark. PAYTAMINE is an amorphous alkaloid accompanying *Paytine.*

HOMOCINCHONINE, $C_{19}H_{22}N_2O$, *cinchonidine of Koch*, is obtained from the bark of *C. rosulenta;* it is lævogyrate, and crystallizes from its alcoholic solution in large prisms. It has been mistaken for *aricine.*

DIHOMOCINCHONINE, $C_{38}H_{44}N_4O_2$, is an amorphous alkaloid obtained from *C. rosulenta.* It is dextrogyrate.

HOMOCINCHONIDINE, $C_{19}H_{22}N_2O$, is also obtained from *C. rosulenta.* It crystallizes in large prisms, and forms a neutral sulphate containing six molecules of water, which may be had in commerce. Its existence is denied by Skraup.

CUSCONINE, $C_{28}H_{26}N_2O_4,2H_2O$, was discovered by Leverköhn. It is a constituent of the cusco bark, *C. pubescens* var. *Pelletieriana*, and Hesse has recently found it in Cuprea bark. It is nearly insoluble in water, soluble in 35 parts of ether, more easily in alcohol, very soluble in chloroform. It may be distinguished from other cinchona alkaloids by forming with sulphuric acid a neutral sulphate, which is amorphous, gelatinous, and yellow, and insoluble in an excess of the acid.

CONCUSCONINE, $C_{23}H_{26}N_2O_4$, discovered by Hesse. It is tasteless.

CUSCONIDINE is an amorphous alkaloid found in cusco bark, accompanying cusconine.

ARICINE, $C_{23}H_{28}N_2O_4$. *Cinchovatine.* This alkaloid, found in cusco bark, and quite recently in Cuprea bark, was formerly believed by Hesse to be identical with cinchonidine. Pelletier and Cariol obtained *aricine* as far back as 1829 (see note, p. 308, 14th ed. U. S. D.). Its separate existence is now not doubted. It crystallizes in prisms, and its salts are of sparing solubility.

PARICINE, $C_{16}H_{18}N_2O$, is found with quinamine in the bark of *C. succirubra* of Darjeeling, and, according to Hesse, it may be separated from all the cinchona alkaloids with which it may be associated in solution by treating with sodium carbonate, which precipitates paricine first.

DICINCHONINE, $C_{38}H_{44}N_4O_2$, exists in the bark of *C. rosulenta* and *C. succirubra*, and may also be obtained by fractional precipitation from the mixed amorphous alkaloids before melting, but not from commercial chinoidine.

DIQUINIDINE, *dichonchinine of Hesse*, $C_{40}H_{46}N_4O_3$, is found principally in chinoidine which has been obtained from barks containing quinine and quinidine. It is dextrogyrate, produces a fluorescent solution with diluted sulphuric acid, and responds to the thalleioquin reaction.

JAVANINE, obtained by Hesse from *C. calisaya* var. *Javanica.*

CINCHOLINE, a pale-yellow liquid alkaloid, having an odor recalling that of quinoline or chinoline, discovered by Hesse in 1882. (See *P. J. Tr.*, May 6, 1882.)

CHAIRAMINE, $C_{22}H_{26}N_2O_4$, discovered by Hesse in *Remijia Purdieana*, occurs in white needles which are readily soluble in ether and chloroform. (*Ann. d. Chem.*, 225, p. 211.)

CONCHAIRAMINE, $C_{22}H_{26}N_2O_4 + H_2O + C_2H_6O$, also discovered by Hesse, crystallizes with both water and *alcohol of crystallization.* It is soluble in hot alcohol, ether, and chloroform. The alcoholate dissolves in sulphuric acid containing molybdic acid, giving a brown coloration, which soon becomes intensely green. (*Ann. d. Chem.*, 225, p. 211.)

HYDROCINCHONINE, $C_{20}H_{26}N_2O$, discovered by Caventou, is obtained by treating cinchonine with potassium permanganate. It is soluble in 1300 parts of water, more soluble in alcohol and in ether. The statement that it may be found in commercial cinchonine has not been confirmed. Hesse states that it may be found in Cuprea bark.

CONCHAIRAMIDINE, $C_{22}H_{26}N_2O_4 + H_2O$, crystallizes in white needles, and is very soluble in ether, chloroform, alcohol, benzene, and acetone. (*Ann. d. Chem.*, 225, p. 211.)

Of the artificial bases, QUINAMICINE and QUINAMIDINE are isomeric; they are both amorphous, and are produced by heating quinamine in contact with diluted sulphuric acid. If the action of sulphuric acid be continued at 120° C. (248° F.) to 130° C. (266° F.), an amorphous brownish substance is formed which may be precipitated by sodium carbonate, and is insoluble in ether. Hesse has named this PROTOQUINAMICINE.

DIQUINICINE, $C_{40}H_{46}N_4O_3$, also termed *diconchinine* and *apodiquinidine*, is one of the chief amorphous alkaloids in commercial chinoidine; its formula indicates its relation to quinine or

quinidine. By deducting one molecule of water from a double molecule of either there results diquinicine, thus: $2C_{20}H_{24}N_2O_2 - H_2O = C_{40}H_{46}N_4O_3$.

DICINCHONICINE, $C_{38}H_{42}N_4O$?, *dichonchonine* or *apodicinchonine*, is derived from cinchonine and cinchonidine, and found in commercial chinoidine. It probably exists in bark in an amorphous condition.

APOQUINAMINE is isomeric with homocinchonine, and is prepared by boiling quinamine or quinamidine with hydrochloric acid for a short time. It is white, amorphous, soluble in ether, alcohol, and diluted hydrochloric acid. HOMOCINCHONICINE is prepared from homocinchonidine just as cinchonicine and quinicine are prepared from cinchonine and quinine,—*i.e.*, by heating their sulphates.

The other constituents of Cinchona bark are of less importance.

QUINIC ACID (*Cinchonic* or *Kinic Acid*), $C_7H_{12}O_6$. This acid was isolated as early as 1785 by Hofmann, an apothecary of Leer, who obtained it from the calcium salt from cinchona. It exists in a number of important plants,—ivy, oak, elm, ash, coffee, etc. It may be desirable to procure the alkaloids in the state of saline combination in which they exist in the bark, since it is possible that they may exert an influence over the system in this state somewhat different from that produced by their combinations with the sulphuric or other mineral acid. As it is impossible to procure the quinates immediately from the bark in a pure state, it becomes necessary first to obtain the quinic acid separately, which may thus become of some practical importance. We shall, therefore, briefly describe the mode of procuring it, and its characteristic properties. It is usually prepared from calcium quinate, the residue obtained in the manufacture of quinine sulphate (see *Quininæ Sulphas*) by decomposing an aqueous solution of calcium quinate with oxalic acid, filtering out the precipitated calcium oxalate, and evaporating the filtrate to the crystallizing point; or by evaporating the infusion of bark to a solid consistence, and treating the extract with alcohol, we have in the residue a viscid matter consisting chiefly of mucilage with calcium quinate, which is insoluble in alcohol. If an aqueous solution of this substance be formed, and allowed to evaporate at a gentle heat, crystals of the quinate will be deposited, which may be purified by a second crystallization. The salt thus obtained, being dissolved in water, is decomposed by means of oxalic acid, which precipitates the lime and leaves the *quinic acid* in solution. This may be procured in the crystalline state by spontaneous evaporation, though as usually prepared it is in the form of a thick syrupy liquid. The crystals are transparent and colorless, sour to the taste, soluble in 2 parts of water, but less soluble in alcohol, and almost insoluble in ether. By heating quinic acid or a quinate with manganese dioxide and sulphuric acid, we get yellow crystals of *kinone*, better known as *quinone*, $C_6H_4O_2$; a reaction which may be used for ascertaining the presence of quinic acid. The cinchonine and quinine quinates may be obtained either by the direct combination of their constituents, or by the mutual decomposition of the sulphates of those alkaloids and calcium quinate. *Cinchonine quinate* has a bitter and astringent taste, is very soluble in water, is soluble also in alcohol, and is crystallized with difficulty. *Quinine quinate* is also very soluble in water, but less so in rectified alcohol. Its taste is very bitter, resembling that of yellow bark. It crystallizes in beautiful stellate groups, which are opaque or semi-transparent. The salt is with difficulty obtained free from color, and only by employing the ingredients in a state of extreme purity. (*Ann. de Chim. et de Phys.*, Juillet, 1829.) Lautemann found, in experiments upon himself, that quinic acid, when taken into the system, undergoes a conversion into hippuric acid and in this state escapes with the urine. (*Ann. der Chem. und Pharm.*, cxxv. 9.) M. Rabuteau has investigated the physiological properties of quinic acid, and has found it closely to resemble the ordinary vegetable acids, being harmless in its effects on the system, and forming with water a refreshing drink like lemonade. Like other vegetable acids, also, it is decomposed in the system, forming, when taken in the state of an alkaline salt, a carbonate of the alkali in the blood, and rendering that fluid alkaline. (*Am. Journ. of Med. Sci.*, Oct. 1872, p. 524.) Quinic acid is said by Zwenger to have been found in the leaves of *Vaccinium myrtillus*. (*A. J. P.*, March, 1861, p. 128.)

QUINOVIN, *Kinovin*, or *Chinovin*. *Kinovic Bitter*, $C_{38}H_{62}O_{11}$. Originally discovered in the false bark called quinquina nova, or new bark, this substance has since been found in the Calisaya bark, and probably exists, in greater or less proportion, in all the Cinchona barks. It was detected by De Vrij not only in the bark but also in the wood and leaves of *C. calisaya* and *C. lucumæfolia*. (*Journ. de Pharm.*, Avril, 1860, pp. 225, 258.) It is white, uncrystallizable, almost insoluble in water, but readily dissolved by alcohol and ether. It is very bitter, and, as it is asserted to have no febrifuge virtues, may on this account mislead the judgment in relation

to the activity of the bark in which it may be found. Some barks are said to owe their bitterness mainly to this ingredient. Winckler gives, as a certain test of its presence in any bark, copper sulphate, which is indifferent to infusion of bark containing none of this principle, but detects the smallest proportion of it by producing a dirty-green color, soon followed by the deposition of a fine similarly colored powder. This is a salt of copper, and has a very bitter and metallic taste. (See *A. J. P.*, xxv. 343.)

Quinovin in alcoholic solution was shown in 1859 by Hlasiwetz to be resolved by means of hydrochloric acid gas into quinovic acid, $C_{24}H_{38}O_4$, and an uncrystallizable sugar, *mannitan*, $C_6H_{12}O_5$, by assimilation of H_2O. The formation of quinovic acid takes place more easily if kinovin is placed in contact with sodium amalgam and spirit of wine, when after 12 hours mannitan and sodium quinovate are formed. (*Pharmacographia*, 2d ed., p. 364.)

Liebermann and Giesel (*Berichte*, xvi. 987) believe that two modifications exist, *α-quinovin* and *β-quinovin*, the former in Cinchona, the latter in Cuprea bark: *α*-quinovin is a white crystalline powder, nearly insoluble in cold and hot water, but soluble in caustic alkalies, lime water, ammonia, and glacial acetic acid, soluble with difficulty in chloroform, ether, and benzin; it dissolves in 57 parts of nearly absolute alcohol. *β*-quinovin closely resembles *α*-quinovin, but is not soluble in ether, and crystallizes readily from dilute alcohol.

De Vrij proposes the following method of isolating quinovin. Macerate powdered cinchona with a very weak solution of caustic potassa or soda, precipitate the filtered liquid with an acid, redissolve the precipitate in milk of lime to separate the cinchonic red, filter and precipitate the solution boiling hot with hydrochloric acid, separate the precipitate, wash it, express as much as possible, and lastly dry it on porous stones, and powder it. For a process for preparing quinovin from by-products, see Allen's *Organic Analysis*, 1892, vol. iii., Part II., p. 443. Thus prepared, the quinovic bitter forms soluble compounds with magnesia and lime, and has been employed, in this mode of combination, as a tonic in the hospital of Batavia, with encouraging success. (*Journ. de Pharm.*, Avril, 1860, p. 258.) Quinovic or *Kinovic Acid*, resulting, as before stated, from the decomposition of quinovin, and possessing the formula $C_{32}H_{48}O_6$, is white, in rhomboidal crystals, insoluble in water, but slightly soluble in ether, somewhat more so in boiling alcohol, but very soluble in ammonia and the fixed alkalies, the solutions frothing like soap water. On adding an acid to an alkaline solution of quinovic acid, a hydrate of quinovic acid is thrown down as a very voluminous jelly, the whole contents of the vessel gelatinizing. Dr. Kerner (*Deutsche Klin.*, xx. 81) speaks very favorably of quinovic acid as an excellent and at the same time perfectly safe tonic, which produces no narcotic symptoms, and given to adults, in the quantity of half or three-quarters of an ounce, causes not the slightest ill effect. He prefers it in the form of calcium quinovate, of which forty grains (2·6 Gm.) is the average dose. (*Am. Journ. Med. Sci.*, Oct. 1869, 543.)

By the experiments of Henry, Jr., and Plisson, it may be considered as established that the alkaloids of the different varieties of bark are combined at the same time with quinic acid and with one or more of the coloring matters which, in relation to these substances, appear to act the part of acids. This idea was originally suggested by Robiquet. (*Journ. de Pharm.*, xii. 282, 369.) The compounds of quinine, cinchonine, etc., with the coloring matter are scarcely soluble in water, while their quinates are very soluble.

The odor of bark appears to depend on a *volatile oil*, which Fabroni and Trommsdorff obtained by distillation with water. The oil floated on the surface of the water, was of a thick consistence, and had a bitterish, acrid taste, with the odor of bark.

The *fatty matter*, which was first obtained pure by M. Laubert, is of a greenish color as obtained from the pale bark, orange yellow from the yellow. It is insoluble in water, soluble in boiling alcohol, which deposits a part of it on cooling, very soluble in ether even cold, and saponifiable with the alkalies.

Cinchofulvic Acid. The *cinchonic red* of Reuss, identical with the *insoluble red coloring matter* of Pelletier and Caventou, $C_{12}H_{14}O_7$, is reddish brown, insipid, inodorous, largely soluble in alcohol, especially when hot, and almost insoluble in ether or water, though the latter dissolves a little at the boiling temperature. The acids promote its solubility in water. It precipitates tartar emetic, but not gelatin; but if treated with a cold solution of potassa or soda, or with ammonia, lime, or baryta with heat, and then precipitated by an acid, it acquires the property of forming an insoluble compound with gelatin. It yields protocatechuic acid, $C_7H_6O_4$, when fused with caustic potash. It is most abundant in the red bark (over 10 per cent.), and least so in the pale.

The *yellow coloring matter* has little taste, is soluble in water, alcohol, and ether, precipitates neither gelatin nor tartar emetic, and is itself precipitated by subacetate of lead.

Cinchotannic Acid. *Cinchotannin*, $C_{14}H_{16}O_9$. *Tannic acid*, *tannin*, or *soluble red coloring matter* of Pelletier and Caventou, has been considered as possessing all the properties which characterize the proximate vegetable principles associated together under the name cinchotannic acid. It is a glucoside existing in cinchona barks in the proportion of 3 to 4 per cent. It has a brownish-red color and an austere taste, is soluble in water and alcohol, combines with metallic oxides, and produces precipitates with the salts of iron, which vary in color according to the variety of bark, being deep green with the pale bark, blackish brown with the yellow, and reddish brown with the red. It also forms white precipitates with tartar emetic and gelatin, and readily combines with atmospheric oxygen, becoming insoluble. It must, however, differ materially from the tannic acid of galls, which could not exist in aqueous solutions containing cinchonine and quinine without forming insoluble compounds with them. Rembold has shown that when cinchotannic acid is boiled with diluted sulphuric acid cinchonic red is produced, sugar being formed at the same time.

Cinchocerotin, $C_{27}H_{48}O_2$. This substance was discovered by Dr. Kerner in flat Calisaya bark from South America. He obtained it in white, very light, crystalline scales. It is not soluble in boiling water, nor in hydrochloric, dilute sulphuric, or glacial acetic acid, but dissolves readily in ether, chloroform, and alcohol. (*A. J. P.*, 1883, p. 357.)

Incompatibles. Of the relations of bark to the several solvents employed in pharmacy we shall speak hereafter, under the heads of its infusion, decoction, and tincture; where we shall also have an opportunity of mentioning some of the more prominent substances which afford precipitates with its liquid preparations. It is sufficient at present to state that all the substances which precipitate the infusion of bark do not by any means necessarily affect its virtues, as it contains several inert ingredients which form insoluble compounds with bodies that do not disturb its active principles. As *tannic acid* forms with the alkaloids compounds insoluble in water, it is desirable that substances containing this acid in a free state should not be prescribed in connection with the infusion or decoction of bark; for, though these insoluble tannates might be found efficacious if administered, yet, being precipitated from the liquid, they would be apt to be thrown away as dregs, or at any rate would communicate, if agitated, an unpleasant turbidness. The same may be said of the *tincture* and *compound solution of iodine*, which form insoluble compounds with all the cinchona alkaloids, and of the *alkalies*, *alkaline carbonates*, and *alkaline earths*, which precipitate them from their aqueous solution.

Estimation of Value. It is evident, from what has been said, that an infusion of bark, on account of the tannin-like principle which it contains, may precipitate gelatin, tartar emetic, and the salts of iron, without having a particle of cinchonine, quinine, or other alkaloid in its composition, and that consequently any inference as to its value, drawn from these chemical properties, would be fallacious; but, as the active principles are thrown down by the tannic acid of galls, no bark can be considered good which does not afford a precipitate with the infusion of this substance.*

It is impossible to determine with accuracy the relative proportion of the active ingredients in the different varieties of cinchona, as the quantity is by no means uniform in different specimens of the same variety. The results of the most recent experiments have been already stated under the head of the several varieties of bark described. But it is highly important, in relation to any particular sample of bark, to be able to ascertain its medicinal efficiency, which is measured by the quantity of the peculiar cinchona alkaloids it may contain. In 1880 the U. S. Pharmacopœia for the first time in its history gave a process for assaying Cinchona bark; this was deemed necessary because of the impossibility of judging of the quality of the bark by its physical appearances. The manufacturing chemist never trusts to anything short of a careful chemical assay, and Cinchona bark should never be dispensed or used without

* *Grahe's Test.* A test of the Cinchona barks containing one or more of their characteristic alkaloids has been proposed by Grahe. It is founded on the fact that when these barks are exposed to destructive distillation a product is obtained of a bright carmine color, which is yielded by no other bark under the same circumstances, and not by cinchona unless it contain one or more of its peculiar alkaloids. Nor do the pure alkaloids afford it; but, if mixed with a little acetic, quinic, tannic, citric, or tartaric acid, they exhibit the reaction, showing that in the bark it takes place between the alkaloids and organic acids contained in it. Grahe applies the test by heating a piece of the bark weighing from five to ten grains in an ordinary test-tube, and gradually increasing the heat to redness. Whitish smoke, and watery vapor condensing on the surface of the tube, are first given off, which are soon followed by the appearance of redness in the fumes, and by the deposition, an inch above the heated part, of a red pulverulent film, which is gradually changed into a thick, oily liquid, running down the glass in drops or streaks of a fine carmine color. (*Chemisches Centralblatt*, Feb. 17, 1858, p. 97.)

having its quality tested or certified to by a competent authority. The following official process of assay is much simpler than that of the U. S. Pharm. 1880, and will give sufficiently accurate results for the uses of the pharmacist. Each manufacturer and quinologist usually has his own secret process, and a method which will accurately differentiate the quantities of the alkaloids is usually difficult and unreliable in the hands of the inexperienced.

"ASSAY OF CINCHONA. I. *For Total Alkaloids.* Cinchona, in No. 80 (or finer) powder, and completely dried at 100° C. (212° F.), *twenty grammes;* Alcohol, Ammonia Water, Chloroform, Ether, Normal Sulphuric Acid (volumetric solution), Potassium Hydrate volumetric solution, each, *a sufficient quantity.* To 20 Gm. of Cinchona, in very fine powder, and contained in a bottle provided with an accurately ground glass stopper, add 200 C.c. of a previously prepared mixture of 19 volumes of alcohol, 5 volumes of chloroform, and 1 volume of ammonia water, stopper the bottle, and shake it thoroughly and frequently during four hours. Then separate the liquid by pouring it into another bottle through a funnel containing a pellet of cotton, in such a manner that no material loss by evaporation may result. Transfer 100 C.c. of the clear filtrate (representing 10 Gm. of Cinchona) to a beaker, and evaporate it to dryness. Dissolve the residue of crude alkaloids thus obtained in 10 C.c. of water and 4 C.c. of normal sulphuric acid, with the aid of a gentle heat, filter the cooled solution into a separatory funnel, and wash the beaker and filter until the filtrate no longer has an acid reaction, using as small a quantity of water as possible. Now add 5 C.c. of potassium hydrate volumetric solution, or such an amount as will render the liquid decidedly alkaline, and extract the alkaloids by shaking the mixture, first with 20 C.c., and then repeatedly with 10 C.c., of chloroform, until a drop of the last chloroform extraction, when evaporated on a watch-glass, no longer leaves a residue. Evaporate the united chloroformic extracts in a tared beaker, dry the residue at 100° C. (212° F.), and weigh. The weight found, multiplied by *ten* (10), will give the percentage of *total alkaloids* in the specimen of Cinchona tested.

"*II. For Quinine.* Transfer 50 C.c. of the clear filtrate remaining over from the preceding process (and representing 5 Gm. of Cinchona) to a beaker, evaporate it to dryness, and proceed as directed in the assay for total alkaloids, using, however, only one-half the amounts of volumetric acid and alkali there directed. Add the united chloroformic extracts containing the alkaloids in solution, gradually, and in small portions at a time, to about 5 Gm. of powdered glass contained in a porcelain capsule placed over a water-bath, so that, when the contents of the capsule are dry, all or nearly all of the dry alkaloids shall be in intimate admixture with the powdered glass, and the chloroform be completely expelled. Now moisten the residue with ether, and, having placed a funnel containing a filter of a diameter of 7 Cm., and well wetted with ether, over a small graduated tube (A), transfer to the filter the ether-moistened residue from the capsule. Rinse the latter several times, if necessary, with fresh ether, so as to transfer the whole of the residue to the filter, then percolate with ether added drop by drop, until exactly 10 C.c. of percolate have been obtained. Then collect another volume of 10 C.c., by similar, slow percolation with ether, in a second graduated tube (B). Transfer the contents of the two tubes completely (using ether for washing) to two small, tared capsules, properly marked (A and B) so as to avoid confusion, evaporate to a constant weight at 100° C. (212° F.), and weigh them. (The residue in A will contain practically all the quinine, together with a portion of the alkaloids less soluble in ether; the residue in B will consist almost entirely of these alkaloids.) From the amount of residue obtained in capsule A deduct that contained in B, and multiply the remainder by *twenty* (20). The product will represent, approximately, the percentage of *quinine* (containing one molecule of water) in the specimen of Cinchona tested." *U. S.*

The Br. Pharmacopœia gives the following method for testing Red Cinchona bark:

"*Test.* When used for purposes other than that of obtaining the alkaloids or their salts, it should yield between 5 and 6 per cent. of total alkaloids, of which not less than half should consist of quinine and cinchonidine, as estimated by the following methods.

"Mix 20 grammes of Red Cinchona Bark, in No. 60 powder, with 6 grammes of *calcium hydroxide;* slightly moisten the powders with 20 cubic centimetres of *water;* mix the whole intimately in a small porcelain dish or mortar; allow the mixture to stand for an hour or two, when it will present the characters of a moist dark brown powder, in which there should be no lumps or visible white particles. Transfer this powder to a suitable flask fitted with a small reflux condenser, add 130 cubic centimetres of *benzolated amylic alcohol*,* boil them together

* "Made by mixing together three volumes of benzol and one of amylic alcohol, and decanting the supernatant fluid from any deposited water." *Br.*

for about half an hour, decant the liquid on to a filter, leaving the powder in the flask; add more of the *benzolated amylic alcohol* to the powder, and boil and decant as before; repeat this operation a third time; then turn the contents of the flask on to the filter, and wash by percolation with more of the *benzolated amylic alcohol* until the Bark is exhausted. Introduce the collected filtrate, while still warm, into a stoppered glass separator; add to it 2 cubic centimetres of *diluted hydrochloric acid*, mixed with 12 cubic centimetres of *water;* shake them well together, and when the acid liquid has separated this may be drawn off, and the process repeated with *water* slightly acidulated with *hydrochloric acid*, until the whole of the alkaloids have been removed. The liquid should then, while warm, be carefully and exactly neutralized with *solution of ammonia*, and concentrated to the bulk of 16 cubic centimetres. If now about 1·5 grammes of *sodium potassium tartrate*, dissolved in twice its weight of *water*, be added to the solution, and the mixture stirred with a glass rod, insoluble tartrates of quinine and cinchonidine will separate completely in about an hour, and these collected on a filter, washed, and dried in a water-oven, will contain eight-tenths of their weight of the alkaloids, quinine and cinchonidine, which, multiplied by 5, gives the weight of those alkaloids present in 100 grammes of the Bark. To the mother-liquor from the preceding process add *solution of ammonia* in slight excess. Collect, wash, and dry the precipitate, which will contain the other alkaloids. The weight of this precipitate, multiplied by 5, and added to the percentage weight of the quinine and cinchonidine, gives the percentage weight of total alkaloids."

The German Pharmacopœia gives the following method: "The powdered bark is assayed as follows: Shake 20 Gm. of it strongly and repeatedly with a mixture of 10 Gm. of water of ammonia, 20 Gm. of alcohol, and 170 Gm. of ether, and, after a day, decant 120 Gm. of the clear liquid. To this liquid add 3 C.c. of volumetric hydrochloric acid, remove the ether by distillation or evaporation, and again add, if necessary, enough hydrochloric acid to render the solution acid. Then filter, and mix the cold filtrate with 3·5 C.c. of volumetric solution of potassa. When the alkaloids have subsided, drop more of the solution of potassa into the clear supernatant liquid, until nothing more is thrown down. Finally, collect the whole of the precipitate on a filter, and wash it repeatedly with small portions of water, until drops of the wash water allowed to come in contact with the surface of a cold, aqueous, neutral, saturated solution of sulphate of quinine no longer produce a turbidity. When the alkaloids have drained, press them gently between bibulous paper, and, having dried them sufficiently in the air to permit their being removed to a watch-glass, dry them completely, first over sulphuric acid, and, finally, by means of a water-bath. The weight of alkaloids procured by this method should not be less than 0·42 Gm. When a small portion of the same is boiled with 300 parts of water, the filtrate, after cooling, should yield flakes of quinine. When to 5 parts of this solution, after being cooled and decanted, 1 part of chlorine water is added, and water of ammonia immediately dropped in, the liquid should acquire a beautiful green color."* *Ph. Germ.*

* *Dr. E. R. Squibb's Method of Assaying Cinchona Bark.* Take of the powdered cinchona 5 grammes = 77·16 grains; lime, well burnt, 1·25 grammes = 19·29 grains; amylic alcohol, stronger ether, purified chloroform, normal solution of oxalic acid, normal solution of sodium and water, of each a sufficient quantity; or double all the quantities throughout, as well as size of vessels, etc., if the barks be poor, or if it be desired to divide the errors of manipulation. Add to the lime contained in a 10-Cm. = 4-inch capsule, 30 C.c. = 1 fluidounce of hot water, and when the lime is slaked, stir the mixture, add the cinchona, stir very thoroughly, and digest in a warm place for a few hours, or overnight. Then dry the mixture at a low temperature on a water-bath, rub it to powder in the capsule, and transfer it to a flask of 100 C.c. = 3·3 fluidounces capacity, and add to it 25 C.c. = $\frac{5}{6}$ fluidounce of amylic alcohol. Cork the flask, and digest in a water-bath at a boiling temperature, and with frequent vigorous shaking, for four hours. Then cool and add 60 C.c. = 2 fluidounces of stronger ether, sp. gr. 0·728, and again shake vigorously and frequently during an hour or more. Filter off the liquid through a double filter of 10 Cm. = 4 inches diameter, into a flask of 150 C.c. = 5 fluidounces capacity, and transfer the residue to the filter. Rinse out the flask on to the filter with a mixture of 10 volumes of amylic alcohol and 40 of stronger ether, and then percolate the residue on the filter with 15 C.c. = half a fluidounce of the same mixture, added drop by drop from a pipette to the edges of the filter and surface of the residue. Return the residue to the flask from whence it came, add 30 C.c. = 1 fluidounce of the amylic alcohol and ether mixture, shake vigorously for five minutes or more, and return the whole to the filter. Again percolate the residue with 15 C.c. of the menstruum, applied drop by drop from a pipette as before. Then put the filter and residue aside, that it may be afterwards tested in regard to the degree of exhaustion. Boil off the ether from the filtrate in the flask by means of a water-bath, taking great care to avoid igniting the ether vapor, and also to avoid explosive boiling by having a long wire in the flask. When boiled down as far as practicable in the flask, transfer the remainder to a tared capsule of 10 Cm. = 4 inches diameter, and continue the evaporation on a water-bath until the contents are reduced to about 6 grammes = 92 grains. Transfer this to a flask of 100 C.c. = 3·3 fluidounces capacity, rinsing the capsule into the flask with not more than 4 C.c. = 64 minims of amylic alcohol. Then add 6 C.c. = 96 minims of water, and 4 C.c. = 64 minims of normal solution of oxalic acid, and shake vigorously and frequently during half an hour. Pour the mixture while intimately mixed on to a well-wetted double filter of 12 Cm. = 4$\frac{3}{4}$ inches diameter, and filter off the watery solution from the amylic alcohol into a tared capsule of 10 Cm. = 4 inches diameter. Wash the filter and contents with 5 C.c. = 80 minims of water,

It is usually sufficient to ascertain the quantity of total alkaloids in bark, for this is really a test of the efficacy of the bark for pharmaceutical purposes; since all the organic alkaline principles contained in it are efficient as medicines, and in all probability in a nearly equal degree. But for manufacturing purposes it is necessary to push the investigation further, and ascertain the proportion of the several alkaloids in the mixture.

From the most recent and carefully conducted assays, it appears that the best official yellow Calisaya bark, the finest red bark, and the finest fibrous Carthagena bark (*soft Pitaya*) are about equal in their amount of alkaloids, each containing from 3 to 4 per cent., and the Indian and Java barks frequently exceed these yields; De Vrij obtained from bark of *C. officinalis* grown at Ootacamund total alkaloids as high as 11·96 per cent. (9·1 per cent. of which was quinine). The highest yield yet recorded was obtained by De Vrij from Ootacamund bark, 13·5 per cent., the greater part of which was quinine.* Between these and the barks of lowest value there is every grade of productiveness, down to a mere trace of alkaloidal matter.†

The quantities of cinchona and other barks used in the manufacture of quinine imported into the United States during the year 1896 was 2,699,789 lbs., valued at $165,699, and for 1897, 2,537,693 lbs., valued at $142,303. In the same years the importations of sulphate of quinine amounted to 2,950,078 ounces, valued at $754,050, and 2,714,147 ounces, valued at $489,821.70 respectively.

Medical Properties and Uses. This valuable remedy was unknown to the civilized

applied drop by drop from a pipette to the edges of the filter and surface of the amylic alcohol. Then pour the amylic alcohol back into the flask over the edge of the filter and funnel, rinsing the last portion in with a few drops of water. Add 10 C.c. = 160 minims of water, and 1 C.c = 16 minims of normal solution of oxalic acid; again shake vigorously for a minute or two, and return the whole to the wetted filter, and filter off the watery portion into the capsule with the first portion. Return the amylic alcohol again to the flask, and repeat the washing with the same quantities of water and normal oxalic solution. When this has drained through, wash the filter and contents with 5 C.c. = 80 minims of water, applied drop by drop from a pipette. Evaporate the total filtrate in the capsule on a water-bath, at a low temperature, until it is reduced to about 15 grammes = 241 grains, and transfer this to a flask of 100 C.c. = 3·3 fluidounces capacity, rinsing the capsule into the flask with 5 C.c. = 80 minims of water. Add 20 C.c. = 66 fluidounces of purified chloroform, and then 6·1 C.c. = 98 minims of normal solution of sodium, and shake vigorously for five minutes or more. While still intimately mixed by the shaking, pour the mixture upon a filter of 12 Cm. = 4¾ inches diameter, well wetted with water. When the watery solution has passed through, leaving the chloroform on the filter, wash the filter and chloroform with 5 C.c. = 80 minims of water, applied drop by drop. Then transfer the chloroform solution, by making a pin-hole in the point of the filter, to another filter of 10 Cm. = 4 inches diameter, well wetted with chloroform, and placed over a tared flask of 100 C.c. = 3·3 fluidounces capacity. Wash the watery filter through into the chloroform-wet filter with 5 C.c. = 80 minims of purified chloroform, and when this has passed through into the flask, wash the chloroform-wet filter also with 5 C.c. = 80 minims of chloroform applied drop by drop to the edges of the filter. When the whole chloroform solution of alkaloids is collected in the flask, boil off the chloroform to dryness in a water-bath, when the alkaloids will be left in watery groups of radiating crystals adhering over the bottom and sides of the flask. Place the flask on its side in a drying stove, and dry at 100° C. = 212° F. to a constant weight. The weight of the contents multiplied by 20 gives the percentage of the total alkaloids of the cinchona in an anhydrous condition, to within ·1 or ·2 of 1 per cent. if the process has been well managed.

* *Quinetum.* Under this name a compound is produced in India and other Eastern countries, which consists of the mixed alkaloids of Red Bark, the object being to produce a cheap febrifuge which will answer all practical purposes and save the cost of refining. The following formula has been adopted by the Dutch Society for the Advancement of Pharmacy: "Red Cinchona bark (the bark of the trunk of *Cinchona succirubra*, grown in Java and India, and containing at least 6 per cent. of alkaloids), in fine powder, 1000 parts; normal hydrochloric acid (volumetric standard), 1000 parts; oxalic acid, 12 parts; solution of soda, q. s.; water, q. s.

"Macerate the cinchona with the hydrochloric acid and 3000 parts of water for at least 12 hours, occasionally stirring. Pour the mixture into a percolator, the lower orifice of which is closed by a linen plug, and, as soon as the liquid runs off clear, displace with water until the liquid running from the percolator is no longer precipitated (though it may be colored) by solution of soda.

"To the strained liquid (which may amount to perhaps 8000 parts) add the oxalic acid dissolved in a little water, and then add *carefully*, under continued stirring, just enough solution of soda until the precipitate which forms at first separates in coherent flakes. Separate this precipitate (which consists of calcium oxalate and cinchona red) by pouring off as much of the still acid clear liquid as is possible, and filter the remainder. To the united liquids add now an excess of solution of soda, let it settle, and collect the precipitate upon a moistened double filter. Wash it with a weak soda solution until the washings have only a light-red color; then wash with the least possible quantity of water, until the washings begin to have a bitter taste. Let the precipitate drain, dry it in the air, and powder it.

"Quinetum is completely soluble in strong, warm alcohol. When 3·1 grammes of quinetum are dissolved in 10 C.c. of normal hydrochloric acid, this solution must be clear, and, on the addition of 2 grammes of Rochelle salt, must yield a precipitate which, when dried, should amount to *at least* 65 per cent. of the weight of the quinetum dissolved." (*N. R.*, 1882, p. 10.)

† To obviate the disadvantages arising from the variable strength of bark, M. Guillermond recommends to fix on an appropriate strength, as indicated by the percentage of quinine, below the highest, yet much above the lowest, and either to select bark of this strength, or to bring that employed to the medium strength, by adding a stronger or weaker bark, as the case may require, in due proportion. He recommends as this standard the yield of 3·2 per cent. of quinine sulphate. This is to be treated by alcohol till entirely exhausted, and the tincture evaporated so as to yield an extract which shall exactly represent the virtues of the bark and shall always have the same strength. From this extract all the preparations of bark are to be made, which will thus always be uniform in strength. (*Journ. de Pharm.*, Août, 1863, p. 124.

world till about the middle of the seventeenth century, though the natives of Peru are generally supposed to have been long previously acquainted with its febrifuge powers. Humboldt, however, is of a different opinion. In his memoir on the Cinchona forests, he states that it is unknown as a remedy to the Indians inhabiting the country where it grows; and, as these people adhere pertinaciously to the habits of their ancestors, he concludes that it never was employed by them. They have generally the most violent prejudices against it, considering it poisonous, and in the treatment of fever prefer the milder indigenous remedies. Ruiz and Pavon, however, ascribe the discovery to the Indians; and Tschudi states, in his Travels in Peru (Am. ed., ii. 280), that the inhabitants of the Peruvian forests drink an infusion of the green bark as a remedy in intermittent fever.* On the other hand, the statements of Humboldt have been confirmed by the travellers Markham and Spence, the former remarking that the native Indian doctors do not use the bark, and the latter that the Cascarilleros of Ecuador believe that their red bark is used solely for dyeing. It is uncertain whether, as Jussieu stated in 1739, the Jesuit fathers received their knowledge from the Indians, or, as Humboldt believes, discovered the virtues of the drug for themselves, having been led to make trial of it by its extreme bitterness. The Countess of Chinchon, wife of the Viceroy of Peru, having in her own person experienced the beneficial effects of the bark, is said, on her return to Spain in the year 1640, to have first introduced the remedy into Europe. Hence the name of *pulvis Comitissæ*, by which it was first known. After its introduction it was distributed and sold by the Jesuits, who are said to have obtained for it the price of its weight in silver. From this circumstance it was called *Jesuits' powder*, a title which it long retained. In 1653, Dr. Chifflet, physician to the Archduke Leopold, directed the attention of all Europe to the bark by his work entitled *Pulvis Febrifugus Orbis Americani*. This gave rise to a very active controversy; the high price of the drug aiding very greatly those who opposed its introduction. According to Sturm, twenty doses in 1658 cost sixty florins. It seems first to have been advertised in England for sale in 1658 by a James Thomson, and by 1660 it was much employed. It still, however, encountered much prejudice and ignorance, and was not made official in the London Pharmacopœia until 1677. Sir Robert Talbot (or Talbor) used it as a secret remedy with so much address and success that in 1679 he cured Charles II. of a tertian, and subsequently sold his secret to Louis XIV. of France, who published it in 1681.

When taken into the stomach, bark usually excites in a short time a sense of warmth in the epigastrium, which often diffuses itself over the abdomen and even the breast, and is sometimes attended with considerable gastric and intestinal irritation. Nausea and vomiting are sometimes produced, especially if the stomach was previously in an inflamed or irritated state; and its action is not unfrequently accompanied by purging. If the dose of the cinchona bark have been large enough, the symptoms of cinchonism may result. (See *Quinine.*) At one time cinchona bark (dose, 10 grains to 1 drachm = 0·65 to 3·9 Gm.) and its preparations were used as antiperiodics, but at present for such purpose one of its alkaloids is always selected. The best preparation for use as a tonic is the *compound tincture.*

CINCHONIDINÆ SULPHAS. U. S. Cinchonidine Sulphate.

(CĬN-ĊHŌ-NĮ-DĪ'NÆ SŬL'PHĂS.)

$(C_{19}H_{22}N_2O)_2H_2SO_4.3H_2O$; 738·52. $(C_{19}H_{22}N_2O)_2H_2SO_4 + 3H_2O$; 768.

"The neutral sulphate of an alkaloid obtained from the bark of various species of Cinchona." *U. S.*

Sulphate of Cinchonidine; Schwefelsaures Cinchonidin, *G.*; Sulfate de Cinchonidine, *Fr.*

This salt is prepared from the mother-liquors obtained in the manufacture of quinine sulphate, and is separated from the sulphates of the other alkaloids by fractional crystallization. The British-India and Javanese cultivated red barks usually contain large quantities of cinchonidine. Of the South American barks, probably the Colombian varieties yield the largest proportion of cinchonidine. Owing to some confusion in naming cinchonidine and quinidine, this alkaloid is sometimes incorrectly called in Germany *chinidine.* Skraup's researches on the composition of cinchonine and cinchonidine (1879) established the correctness of the formula $C_{19}H_{22}N_2O$, instead of the long-accepted formula of Pasteur (1853), $C_{20}H_{24}N_2O$. Skraup's formula has been confirmed by Hesse, and is now generally accepted among chemists. The French Codex of 1884 used it, but the British Pharmacopœia of 1885 retained the old formula.

* Tschudi also observes that he has found the fresh bark more efficacious than the dried, as, in less than half the usual dose, it not only effects cures in a short time, but insures the patient against the return of the disease.

Properties. Cinchonidine sulphate occurs in "white, silky, acicular crystals, without odor, and having a very bitter taste; slightly efflorescent on exposure to air. Soluble, at 15° C. (59° F.), in 70 parts of water, and in 66 parts of alcohol; in 1·42 parts of boiling water, and in 8 parts of boiling alcohol. Also soluble in 1316 parts of chloroform, and almost insoluble in ether. The presence of sulphates of other cinchona alkaloids increases its solubility in ether and chloroform. At 100° C. (212° F.) the salt gives off its water of crystallization. At 215° C. (419° F.) it melts, and, when ignited, it is consumed without leaving a residue. The salt is neutral, or has a faintly alkaline reaction on litmus paper. On adding ammonia water to the aqueous solution of the salt, a white precipitate (cinchonidine) is produced, which is but slightly soluble in ammonia, but dissolves in about 75 parts of ether. If concentrated sulphuric acid be added to a small quantity of the salt, not more than a faintly yellowish color should be developed (limit of *readily carbonizable, organic impurities*). Upon adding to this liquid a crystal of potassium dichromate, a yellowish-green color is produced, which gradually changes to grass-green. Addition of barium chloride test-solution to an aqueous solution of the salt produces a white precipitate insoluble in hydrochloric acid. A solution of the salt (about 1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of the *sulphates of quinine* or *quinidine*). If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0·920 Gm. (absence of an *undue amount of water*). If 0·5 Gm. of the salt be macerated, with frequent agitation, at the ordinary temperature, with 20 C.c. of water, 0·5 Gm. of potassium and sodium tartrate then added, the maceration continued, under repeated agitation, for one hour at 15° C. (59° F.), and the mixture then filtered, the addition of one drop of ammonia water to the filtrate should not produce more than a slight turbidity (absence of more than small proportions of the *sulphates of cinchonine* or *quinidine*)." *U. S.*

Cinchonidine. The alkaloid itself is not official; as usually seen it is in white, light, pulverulent masses. It is crystallizable, soluble in 1680 parts of cold and in a somewhat smaller quantity of hot water, in about 20 parts of alcohol, and in 70 parts of ether. It melts at 206·5° C. (404° F.), and becomes a solid mass of crystals at 190° C. (374° F.). The *acid sulphate* (sometimes called *bisulphate*) is much more soluble in water than the official sulphate. The *cinchonidine salicylate* is neutral and crystalline, insoluble in cold water, sparingly in hot water, easily soluble in alcohol and diluted alcohol. It may be prepared by the direct combination of salicylic acid with the alkaloid. (Rosengarten, *A. J. P.*, 1879, p. 616.) The *hydrobromate* has been employed by Prof. Gubler hypodermically. (*N. R.*, 1879, 366.)* Königs and Husmann having claimed to have converted cinchonine into cinchonidine by the long-continued action of boiling amyl alcohol solution of potash, Paul and Cownley have investigated this treatment. They failed to get such conversion, and consider that the cinchonine used by Königs and Husmann must have been impure. (*Pharm. Journ.*, Feb. 20, 1897.)

Medical Properties. So far as our knowledge goes, this alkaloid influences the system similarly to quinine, the only difference being that it is less powerful. It may be given in doses one-third greater than those of quinine, but should not be relied on in severe cases.

CINCHONINA. U. S. Cinchonine.

$C_{19}H_{22}N_2O$; **293·41.** (CĬN-ĊHŌ-NĪ'NĄ.) $C_{19}H_{22}N_2O$; **294.**

"An alkaloid obtained from the bark of various species of Cinchona." *U. S.*

This alkaloid was introduced for the first time into the U. S. P. 1880. The sulphate has had an extensive use, is again official, and is the source from whence this alkaloid is usually prepared. Cinchonine is most conveniently precipitated from an aqueous solution of cinchonine sulphate by ammonia water. Several processes have been employed for the preparation of cinchonine. One of the simplest is the following. Powdered pale bark is submitted to the action of sulphuric or hydrochloric acid very much diluted, and the solution obtained is precipitated by an excess of lime. The precipitate is collected on a filter, washed with water, and treated with boiling alcohol. The alcoholic solution is filtered while hot, and deposits the cin-

* *Cinchonidine Benzoate* may be made by Byasson's process. Sixty parts of benzoic acid are dissolved in two hundred parts of alcohol, and poured into a porcelain vessel containing three thousand parts of boiling distilled water; two hundred parts of cinchonidine sulphate are dissolved in two thousand parts of water, using sufficient diluted sulphuric acid to effect the solution; this is precipitated with ammonia, and washed with a small quantity of cold water; the moist precipitate of cinchonidine is added to the hot solution of benzoic acid, and filtered while hot. The solution must be made faintly alkaline by the cautious addition of ammonia. On cooling, the cinchonidine benzoate separates in the form of small, thin, prismatic needles, resembling cinchonidine sulphate. The yield is about two hundred parts. (*Pharm. Rec.*, 1884, p. 45.)

chonine when it cools. A further quantity is obtained by evaporation. If not perfectly white, it may be made so by converting it into a sulphate with dilute sulphuric acid, then treating the solution with animal charcoal, filtering, precipitating by an alkali, and redissolving by alcohol in the manner already mentioned. It may also be obtained from the mother-waters of quinine sulphate by diluting them with water, precipitating with ammonia, collecting the precipitate on a filter, washing and drying it, and then dissolving it in boiling alcohol, which deposits the cinchonine in a crystalline form upon cooling. It may be still further purified by a second solution and crystallization. Its formula is now generally accepted as $C_{19}H_{22}N_2O$, the molecular weight of which is 294, as proposed by Skraup, instead of the older formula, $C_{20}H_{24}N_2O$, of Pasteur.

Properties. This alkaloid occurs in "white, lustrous prisms or needles, without odor, at first almost tasteless, but soon developing a bitter after-taste; permanent in the air. Soluble, at 15° C. (59° F.), in 3760 parts of water, and in 116 parts of alcohol; in 3500 parts of boiling water, and in 26·5 parts of boiling alcohol. Also soluble in 526 parts of ether, and in 163 parts of chloroform. At 240° C. (464° F.) the crystals fuse together, and at 258° C. (496·4° F.) they melt, forming a brown liquid.* When ignited, they are consumed without leaving a residue. When placed on moistened, red litmus paper, Cinchonine shows an alkaline reaction. On adding to a neutral or not more than faintly acid solution of Cinchonine, or of any of its salts, enough potassium ferrocyanide test-solution to redissolve the precipitate first formed, and afterwards an acid, a golden-yellow precipitate will be formed, which, when redissolved by gently warming the liquid, will separate, on cooling, in minute scales or needles. On adding an excess of ammonia water to a solution of Cinchonine in a dilute acid, the alkaloid will be precipitated. The precipitate is but feebly soluble in ammonia, and should require not less than 300 parts of ether for solution. A solution of Cinchonine (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (absence of more than traces of *quinine* or *quinidine*). Cinchonine should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*)." *U. S.* Waddington found it to sublime readily, without change, in perfectly characteristic crystals. (*P. J. Tr.*, March, 1868, p. 414.)† Its alkaline character is very decided, as it neutralizes the strongest acids. Of the salts of cinchonine, the sulphate, nitrate, hydrochlorate, phosphate, and acetate are soluble in water. The neutral tartrate, oxalate, and gallate are insoluble in cold water, but soluble in hot water, alcohol, or an excess of acid. Winckler has shown that cinchonine is rendered uncrystallizable or amorphous by sulphuric acid in excess, aided by heat; a fact of importance in the preparation of the sulphate of this alkaloid. (*Chem. Gaz.*, March 15, 1848.) Cinchonine is but little more soluble in carbonic acid water than in pure water, and does not, like quinine, yield crystals of the carbonate on exposure of its carbonic acid solution. (*Comptes-Rendus*, Nov. 7, 1853, p. 727.) It differs from quinine by its rotating the plane of polarization to the right, by the want of fluorescence in its solutions, and by its failing to respond to the thalleioquin test.

Exposed to the air, cinchonine does not suffer decomposition, but very slowly absorbs carbonic acid gas, and acquires the property of effervescing slightly with acids. It is precipitated sulphur yellow by gold terchloride. Chlorine water dissolves it or any of its salts without change; but if ammonia be now added, a white precipitate is produced. It is thus distinguishable from quinine. (See *Quinine*.) Dr. J. W. Bill, U.S.A., proposes potassium ferrocyanide as a very delicate test of cinchonine. If added to the solution of a salt of this alkaloid, it produces a yellowish-white curdy precipitate, which is dissolved upon the application of a gentle heat, but is again deposited, when the liquid cools, as an abundant crop of golden-yellow crystals. No other alkaloid exhibits the same reaction. A cloudy precipitate is produced by the same reagent with a salt of quinine; but this does not happen when the ferrocyanide is in excess; and, if the precipitate be dissolved by heat, no subsidence takes place on cooling. Hence, in the application of this test to cinchonine, a slight excess of the ferrocyanide should be added. (*Am. Journ. of Science and Arts*, July, 1858, p. 108.)

* The melting point of cinchonine has been very variously given: 236° (Hesse), 268·8° (Skraup), 257° (Caventou and Willm). Moreover, if the crystals of cinchonine be kept for some time at a temperature of from 150° to 160° C., they decompose into liquid and volatile bases, which gives it the semblance of fusion at a much lower fusing point. Thus, Allen (*Commerc. Org. Anal.*, 2d ed., vol. iii., part ii., p. 431) gives the fusing point as 165° C.

† It is asserted that the hydrochlorates of quinine, cinchonine, and quinidine, heated on a slip of platinum, short of combustion, emit a purple vapor like iodine. Neither the alkaloids nor their sulphates have this property; but the addition of one-tenth of hydrochlorate will cause the evolution of the colored vapor. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 397.)

By the action of potassium permanganate cinchonine is decomposed, with the effect of producing, at first, an entirely distinct neutral principle, *cinchotenine*, $C_{18}H_{20}N_2O_3 + 3H_2O$, and an alkaloid, which the authors named *hydrocinchonine*, $C_{19}H_{24}N_2O$, as it differs from cinchonine (cinchonia) only in having two additional atoms of hydrogen. The cinchotenine, when further oxidized by the same reagent, yields quinoline and pyridine derivatives (see PART II.), as *cinchonic* (quinoline-carboxylic) *acid*, $C_9H_6N(COOH)$, and *cinchomeronic* (pyridine-dicarboxylic) *acid*, $C_5H_3N(COOH)_2$.

Medical Properties. The physiological action of cinchonine is similar to but less powerful than that of quinine. Thus, Conzen (quoted by Husemann) has found that its action on infusoria and on fermentation is similar to but weaker than that of its sister alkaloid, and that on the movements of the white blood-corpuscles its influence seems transient. Upon dogs, according to Bernatzik's experiments, the lethal dose of cinchonine is to that of quinine as 5 is to 4. As an antiperiodic or tonic, cinchonine exerts an influence similar to that of quinine, but is probably about one-third weaker, and must be used in correspondingly larger dose.

CINCHONINÆ SULPHAS. U. S. Cinchonine Sulphate.

"The sulphate of an alkaloid obtained from the bark of various species of Cinchona and Remijia." *Br.* 1885.

Cinchoniæ Sulphas, *Pharm.* 1870; Cinchoninum Sulfuricum, *P. G.;* Sulfate de Cinchonine, *Fr.;* Schwefelsaures Cinchonin, *G.*

The process official in U. S. P. 1870 is as follows: "Take of the mother-water, remaining after the crystallization of Sulphate of Quinine, in the process for preparing that salt, *a convenient quantity;* Solution of Soda, Alcohol, Diluted Sulphuric Acid, Animal Charcoal, in fine powder, each, *a sufficient quantity.* To the mother-water add gradually, with constant stirring, Solution of Soda, until the liquid becomes alkaline. Collect on a filter the precipitate formed, wash it with water, and dry it. Then wash it with successive small portions of alcohol, to remove other alkaloids which may be present. Mix the residue with eight times its weight of water, and, having heated the mixture, add gradually Diluted Sulphuric Acid until it is saturated and becomes clear. Then boil the liquid with Animal Charcoal, filter it while hot, and set it aside to crystallize. Lastly, drain the crystals, and dry them on bibulous paper. By evaporating the mother-liquid, more crystals may be obtained." *U. S.*

In consequence of its greater solubility, Cinchonine Sulphate remains behind in the mother-water, when quinine sulphate crystallizes, in the process for preparing the latter salt. To separate it from other substances contained in the mother-water, it is decomposed by solution of soda, which is preferable to potassa, as it forms a very soluble salt with sulphuric acid, whereas the potassium sulphate, being of difficult solubility, might fall with the precipitated cinchonine. The precipitate may be safely washed with small portions of alcohol, as the alkaloid is almost insoluble in that liquid when cold. It is next reconverted into the sulphate; and the solution, having been boiled with *unpurified* animal charcoal to decolorize it, and at the same time neutralize any possible excess of sulphuric acid which might interfere with the crystallization of the salt, is filtered while hot, and then allowed to stand. It is particularly important that there should be no excess of sulphuric acid while the solution is exposed to heat, as under this influence the alkaloid is much disposed to become uncrystallizable. Hence the advantage of using unpurified animal charcoal or bone-black, as the calcium carbonate contained in it neutralizes any excess of the acid. The cinchonine sulphate, held in solution by the liquid while hot, is deposited by it, upon cooling, in crystals.

It may be also prepared by first obtaining cinchonine from one of the pale barks; treating this with water acidulated with sulphuric acid, added gradually till the alkaloid is dissolved; then boiling with purified animal charcoal, filtering the solution while hot, and setting it aside to crystallize.

There are two cinchonine sulphates, the neutral and the acid sulphate. The official salt is the neutral sulphate. It is in "hard, white, lustrous, prismatic crystals, without odor, and having a very bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 66 parts of water, and in 10 parts of alcohol; in 13·59 parts of boiling water, and in 3·25 parts of boiling alcohol. Also soluble in 78 parts of chloroform, but almost insoluble in ether. At 100° C. (212° F.) it gives off its water of crystallization, and at 215° C. (419° F.) it melts, forming a brown liquid. When ignited, it is consumed without leaving a residue. The salt is neutral

* The British Pharm. 1885 gave the following formula for this salt: $(C_{20}H_{24}N_2O)_2,H_2SO_4,2H_2O$.

to litmus paper. Addition of ammonia to an aqueous solution of the salt produces a white precipitate which should respond to the reactions and tests given under *Cinchonina*. On adding barium chloride test-solution to an aqueous solution of the salt, a white precipitate is produced, which is insoluble in hydrochloric acid. A solution of the salt (1 in 1000) in diluted sulphuric acid should not exhibit more than a faint blue fluorescence (limit of *quinine* or *quinidine*). If 1 Gm. of the salt be dried at 100° C. (212° F.) until it ceases to lose weight, the residue, cooled in a desiccator, should weigh not less than 0·95 Gm. (absence of an *undue amount of water*). If 1 part of the salt, reduced to powder, be macerated, with frequent agitation, at the ordinary temperature, with 80 parts of chloroform, it should wholly, or almost wholly, dissolve (limit of *quinine* or *cinchonidine*).* The salt should not impart more than a faintly yellowish tinge to concentrated sulphuric acid (limit of *readily carbonizable, organic impurities*)." *U. S.* The *acid sulphate*, or *bisulphate*, $C_{19}H_{22}N_2OH_2SO_4,3H_2O$, is prepared by adding sulphuric acid to the neutral sulphate. According to Baup, 100 parts are soluble in 45 parts of water and in 100 parts of absolute alcohol; it is insoluble in ether. It crystallizes in rhombic octohedrons.

Medical Properties and Uses. Cinchonine sulphate has the same remedial properties as quinine sulphate, but must be given in somewhat larger dose. Tonic dose, a grain or two (0·065–0·13 Gm.) three or four times a day; antiperiodic dose, 15 grains to 40 grains (1·0–2·6 Gm.) between the paroxysms. It may be taken in pill, or in solution made by the addition of dilute sulphuric acid in the proportion of a minim or two drops for each grain of the salt. To lessen the bitterness in taste, it may be given suspended in syrup, without the use of any acid, or with a few grains of powdered liquorice added to the mixture.

"The inner bark of the shoots of Cinnamomum Zeylanicum, Breyne (nat. ord. Laurineæ)." *U. S.* "The dried inner bark of shoots from the truncated stocks of Cinnamomum zeylanicum, Breyn. Obtained from cultivated trees. Imported from Ceylon, and distinguished in commerce as Ceylon cinnamon." *Br.*

Cinnamomi Cortex, *Br.;* Cinnamomum, *U. S.* 1880; Cinnamon Bark; Cortex Cinnamomi Zeylonici; Cinnamomum Acutum, s. Verum; Cannelle de Ceylon, Cannelle, *Fr.;* Brauner Canel, Zeylonzimmt, Zimmt, *G.;* Canella, *It.;* Canela, *Sp.;* Kurundu, *Cingalese;* Karua puttay, *Tamil.*

Both *cinnamomum* and *cassia* were terms employed by the ancients, but whether exactly as now understood it is impossible to determine. The term *cassia*, or *cassia lignea*, has been generally used in modern times to designate the coarser barks analogous to cinnamon. It was probably first applied to the barks from Malabar, and afterwards extended to those of China and other parts of Eastern Asia. It has been customary to ascribe *cassia lignea* to the *Laurus cassia* of Linnæus; but the specific character given by that botanist was so indefinite, and based on such imperfect information, that the species has been almost unanimously abandoned by botanists. The barks sold as cinnamon and cassia in different parts of the world are derived from various species of Cinnamomum.

Gen. Ch. Flowers hermaphrodite or polygamous. *Perianth* six-cleft, the upper half of each segment deciduous. *Stamens* nine, with four-celled anthers, six (opposite the perianth-segments)

* A test distinguishing between quinine sulphate and cinchonine sulphate has been announced by M. Palm, of Russia, in potassium polysulphide, prepared by boiling solution of potassa with an excess of sulphur. When a solution of this sulphide is added to a boiling solution of quinine sulphate, the latter, however small the quantity present, is thrown down as a red terebinthinate mass, which hardens on cooling and then assumes the appearance of a resin; while with cinchonine sulphate a white powder is precipitated containing sulphur. (*Journ. de Pharm.*, Mai, 1864.)

opening inwards without glands, three (opposite three of the above) opening outwards and bearing a gland on each side at the base. *Staminodia* three (opposite the three other outer stamens), with capitate or cordate abortive anthers. *Berry* resting on the enlarged six-lobed base of the perianth." (Bentham, *Flora Hongkongensis.*) As thus defined, the genus Cinnamomum does not include the genus Camphora. (See *Camphora.*)

1. *Cinnamomum zeylanicum.* Nees, *Laurineæ*, 52; Lindley, *Flor. Med.* 329; Hayne, *Darstel. und Beschreib., etc.* xii. 263.—*Laurus cinnamomum.* Linn. This is a tree about 20 or 30 feet high, with a trunk from 12 to 18 inches in diameter and covered with a thick, scabrous bark. The branches are numerous, strong, horizontal, and declining; and the young shoots are beautifully speckled with dark green and light orange colors. The leaves are opposite for the most part, coriaceous, entire, ovate or ovate-oblong, obtusely pointed, and three-nerved, with the lateral nerves vanishing as they approach the point. There are also two less obvious nerves, one on each side arising from the base, proceeding towards the border of the leaf, and then quickly vanishing. The footstalks are short and slightly channelled, and, together with the extreme twigs, are smooth and without the least appearance of down. In one variety the leaves are very broad and somewhat cordate. When mature, they are of a shining green upon their upper surface, and lighter-colored beneath. The flowers are small, white, and arranged in axillary and terminal panicles.* The fruit is an oval berry, which adheres like the acorn to the receptacle, is larger than the black currant, and when ripe has a bluish-brown surface, diversified with numerous white spots. The tree emits no smell perceptible at any distance. The bark of the root has the odor of cinnamon with the pungency of camphor, and yields this principle upon distillation. The leaves have a spicy odor when rubbed, and a hot taste. A volatile oil distilled from them has been introduced into commerce.† The petiole has the flavor of cinnamon. It is a singular fact that the odor of the flowers is to people in general disagreeable, being compared by some to the scent exhaled from newly-sawn bones. The fruit has a terebinthinate odor when opened, and a taste in some degree like that of juniper berries. A fatty substance, called *cinnamon-suet*, is obtained from it when ripe, by bruising it and then boiling it in water, and removing the oleaginous matter which rises to the surface, and concretes upon cooling. It is the prepared bark that constitutes the genuine cinnamon.

This species is a native of Ceylon, where it has long been cultivated. It is said also to be a native of the Malabar Coast, and has at various periods been introduced into Java, the Isle of France, Bourbon, the Cape Verds, Brazil, Cayenne, several of the West India islands, and Egypt, and in some of these places is at this time highly productive, especially in Cayenne, where the plant was flourishing so early as 1755. It is exceedingly influenced, as regards the aromatic character of its bark, by the circumstances of soil, climate, and mode of culture. Thus, we are told by Marshall that in Ceylon, beyond the limits of Negombo and Matura, in the western and southern parts of the island, the bark is never of good quality, being greatly deficient in the aromatic flavor of the cinnamon; and that even within these limits it is of unequal value, from the various influences of exposure, soil, shade, and other circumstances. Cinnamon closely resembling Ceylon cinnamon is said to have been sent to Europe from Brazil.

2. *C. aromaticum.* Nees, *Laurineæ*, 52; Lindley, *Flor. Med.* 330.—*C. cassia.* Blume, Ed. Ph.; Hayne, *Darstel. und Beschreib., etc.* xii. 23.—*Laurus cassia.* Aiton, *Hort. Kew.* ii. 427.—Not *Laurus cassia* of Linn. This is of about the same magnitude as the former species, and,

* Cassia Buds. This spice consists of the calyx of one or more species of Cinnamomum, surrounding the young ovary, and, as stated by Dr. Martius, on the authority of the elder Nees, about one-quarter of the normal size. It is produced in China; and Mr. Reeves states that great quantities of it are brought to Canton from the province which affords cassia. The species which yields it is in all probability the same with that which yields the bark, though it has been ascribed by Nees to *Cinnamomum loureirii.* In favor of the former opinion is the statement of Dr. Christison, that *C. aromaticum*, cultivated in the hot-houses of Europe, bears a flower-bud which closely resembles the cassia bud when at the same period of advancement. Cassia buds have some resemblance to cloves, and are compared to small nails with round heads. The enclosed ovary is sometimes removed, and they are then cup-shaped at top. They have a brown color, with the flavor of cinnamon, and yield an essential oil upon distillation. They may be used for the same purposes as the bark.

† The *cinnamon leaf oil*, as formerly imported into Great Britain, was of two kinds, one containing a considerable quantity of a fatty fixed oil, perhaps cinnamon-suet from the fruit, the other a pure volatile oil. The oil was said to be obtained by distilling the leaves after maceration in sea-water. It resembled the oil of cloves and pimento in sensible properties, having a brownish color, a penetrating, fragrant odor, and a very pungent taste. According to Stenhouse, it was of the sp. gr. 1·053, had an acid reaction, and consisted of eugenol, a neutral substance with the formula $C_{10}H_{16}$, and a minute proportion of benzoic acid. (*P. J. Tr.*, xiv. 319.) This oil seems to have disappeared from commerce; but it has recently been studied by Schimmel & Co. The oil of their own distillation, as also samples distilled in Java, was limpid, sp. gr. 1·056–1·060, and contained 87 per cent. of eugenol and about 0·1 per cent. of cinnamic aldehyde. A cinnamon leaf oil from the Seychelles consisted chiefly of eugenol. *Schimmel & Co.'s Report* for April, 1897, says that of the Ceylon cinnamon oil exported in 1896, amounting to 132,057 ounces, nine-tenths was probably oil of cinnamon leaves, the price of which had risen quite notably.

like it, has nearly opposite, shortly petiolate, coriaceous, entire leaves, of a shining green upon the upper surface, lighter-colored beneath, and furnished with three nerves, of which the two latter vanish towards the point. The leaves, however, differ in being oblong-lanceolate and pointed, and in exhibiting, under the microscope, a very fine down upon the under surface. The footstalks and extreme twigs are also downy. The flowers are in narrow, silky panicles. The plant grows in China, Sumatra, and other parts of Eastern Asia, and is said to be cultivated in Java. It is believed to be the species which furnishes, wholly or in part, the Chinese cinnamon or cassia brought from Canton, and is supposed to be the source of the *cassia buds*.

Besides the two species above described, others have been thought to contribute to the cinnamon and cassia of commerce. In 1839 (*Madras Journ. Lit. and Sci.*, No. 22), Dr. Wight stated that in his belief cinnamon was derived from 12 to 18 specially distinct trees. *C. inners*, Reinw., is distinguished from *C. zeylanicum* by the nervation of its leaves, which are also paler and thinner than those of the official plant, of which, however, it is probably only a variety. It yields the so-called *wild cinnamon* of Japan. *C. loureirii* of Nees, growing in the mountains of Cochin-China near Laos, and in Japan, affords, according to Loureiro, a cinnamon of which the finest kind is superior to that of Ceylon. *C. nitidum*, growing in Ceylon, Java, and on the continent of India, is said to have been the chief source of the drug known formerly by the name of *Folia Malabathri* and consisting of the leaves of different species of Cinnamomum mixed together. *C. culilawan* of the Moluccas yields the aromatic bark called culilawan, noticed in PART II. of this work; and similar barks are obtained from another species of the same region, named *C. rubrum*, and from *C. sintoc* of Java. *Massoy bark*, from which an aromatic volatile oil is obtained called *oil of massoy*, is the product of *C. kiamis*. (Gmelin, *Handbook*, xiv. 380.) In the mountains of Eastern Bengal, at a height of 1000 to 4000 feet, flourish *C. obtusifolium*, Nees, *C. pauciflorum*, Nees, and *C. tamala*, W., and these, with other unknown species, afford quantities of bark which are shipped from Calcutta, Java, Timor, etc., to Europe under the name of *cassia lignea*, *cassia*, *cassia vera*, or *wild cassia*. These barks are mostly highly aromatic, resembling cinnamon more or less closely in flavor, and are distinguished by yielding to cold water an abundant mucilage.

Culture, Collection, Commerce, etc. In Ceylon, cinnamon bark was originally collected exclusively from the tree in a wild state; but the Dutch introduced the practice of cultivating it, which has been continued since the British came into possession of the island. The principal cinnamon gardens are in the vicinity of Columbo. The seeds are planted in a prepared soil at certain distances; and, as four or five are placed in a spot, the plants usually grow in clusters like the hazel-bush. In favorable situations they attain the height of five or six feet in six or seven years; and a healthy bush will then afford two or three shoots fit for peeling, and every second year afterwards from four to seven shoots in a good soil. The cinnamon harvest commences in May and continues till late in October. The first object is to select shoots proper for decortication, and those are seldom cut which are less than half an inch or more than two or three inches in diameter. Before decortication these shoots are trimmed up, and the small pieces, when dried, constitute *cinnamon chips*. The bark is divided by longitudinal incisions, of which two are made in the smaller shoots, several in the larger, and is then removed in strips by means of a suitable instrument. The pieces are next collected in bundles, and allowed to remain in this state for a short time, so as to undergo a degree of fermentation, which facilitates the separation of the epidermis. This, with the green matter beneath it, is removed by placing the strip of bark upon a convex piece of wood and scraping its external surface with a curved knife. The bark now dries and contracts, assuming the appearance of a quill. The peeler introduces the smaller tubes into the larger, and connects them also endwise, thus forming a congeries of quills which is about forty inches long. When sufficiently dry, these cylinders are collected into bundles weighing about thirty pounds and bound together by pieces of split bamboo. The commerce in Ceylon cinnamon was formerly monopolized by the East India Company; but the cultivation is now unrestricted, and the bark may be freely exported upon the payment of a fixed duty. It is assorted in the island into three qualities, distinguished by the designations of *first*, *second*, and *third*. The inferior kinds, which are of insufficient value to pay the duty, are used for the preparation of oil of cinnamon. The exportation from Ceylon was, in 1896, 2,223,865 lbs. of bark and 808,502 lbs. of chips; in 1897, 2,674,537 lbs. of bark and 1,067,051 lbs. of chips.

Properties. Immense quantities of cinnamon are exported from China, the finest of which is little inferior to that of Ceylon, though the mass of it is much coarser. It passes in commerce under the name of *cassia*, and is said by Mr. Reeves to be brought to Canton from the province

of Kwangse, where the tree producing it grows very abundantly. (*Trans. Med.-Bot. Soc.*, 1828, p. 26.)* It has already been stated that this tree is supposed to be the *Cinnamomum aromaticum;* but we have no positive proof of the fact. It is, indeed, asserted that true cinnamon of very fine grade occurs in China, although it never enters foreign commerce, because of the high price which it commands at home. (*P. J. Tr.*, xxi., 1890.) These fine cinnamons are said to be produced in the mountainous district of Annam, or Cochin-China. Cinnamon of good quality is said to be collected in Java; and considerable quantities of inferior quality have been thrown into commerce, as *cassia lignea*, from the Malabar Coast. Manila and the Isle of France are also mentioned as sources whence this drug is supplied. Little, however, reaches the United States from these places. The island of Martinique, Cayenne, and several of the West India islands yield to commerce considerable quantities of cinnamon of various qualities. That of Cayenne is of two kinds, one of which closely resembles, though it does not quite equal, the aromatic of Ceylon, the other resembles the Chinese. The former is supposed to be derived from plants propagated from a Ceylonese stock, the latter from plants which have sprung from a tree introduced from Sumatra. By far the greater proportion of cinnamon brought to this country is imported from China. It is entered as *cassia* and *Saigon cassia* at the custom-house.

From what source the ancients derived their cinnamon and cassia is not certainly known. Neither the plants nor their localities, as described by Dioscorides, Pliny, and Theophrastus, correspond precisely with our present knowledge; but in this respect much allowance must be made for the inaccurate geography of the ancients. It is probable that the Arabian navigators at a very early period conveyed this spice within the limits of the Phœnician and Grecian and subsequently of Roman commerce.

Ceylon cinnamon is in long cylindrical fasciculi, composed of numerous quills, the larger enclosing the smaller. In the original sticks, which are somewhat more than three feet in length, two or three fasciculi are neatly joined at the end, so as to appear as if the whole were one continuous piece. The finest is of a light brownish-yellow color, almost as thin as paper, smooth, often somewhat shining, pliable to a considerable extent, with a splintery fracture when broken. It has a pleasant, fragrant odor, and a warm, aromatic, pungent, sweetish, slightly astringent, and highly agreeable taste. When distilled it affords but a small quantity of essential oil, which, however, has an exceedingly grateful flavor. It is brought to this country from England; but it is costly. The inferior sorts are browner, thicker, less splintery, and of a less agreeable flavor, and are little if at all superior to the best Chinese. The finer variety of *Cayenne cinnamon* approaches in character that above described, but is paler and in thicker pieces, being usually collected from older branches. That which is gathered very young is scarcely distinguishable from the cinnamon of Ceylon. Ceylon cinnamon is in "long, closely rolled quills, composed of eight or more layers of bark of the thickness of paper; pale yellowish-brown; outer surface smooth, marked with wavy lines of bast-bundles; inner surface striate; fracture short-splintery; odor fragrant; taste sweet and warmly aromatic." *U. S.*†

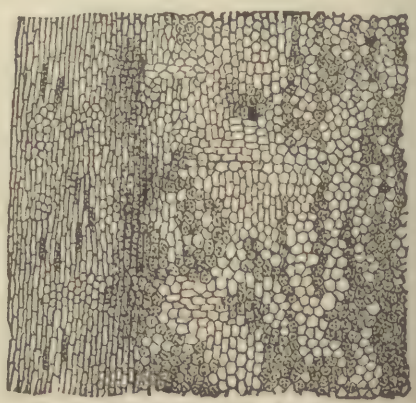
Chinese cinnamon, or *Cassia*, is in tubes from one-eighth of an inch to an inch in diameter, usually single, sometimes double, very rarely more than double. In some instances the bark is rolled very much upon itself, in others is not even completely quilled, forming segments more or less extensive of a hollow cylinder. It is of a redder or darker color than the finest Ceylon cinnamon, thicker, rougher, denser, and breaks with a shorter fracture. It has a stronger, more pungent and astringent but less sweet and grateful taste, and, though of a similar odor, is less agreeably fragrant. It is the kind almost universally kept in our shops. Of a similar character is the cinnamon imported directly from various parts of the East Indies. But under the name of cassia have also been brought to us very inferior kinds of cinnamon, collected from the trunks or large branches of the trees, or injured by want of care in keeping, or perhaps derived from inferior species. It is said that cinnamon from which the oil has been distilled is sometimes fraudulently mixed with the genuine. These inferior kinds are detected, independently of their greater thickness and coarseness of fracture, by their deficiency in the peculiar sensible properties of the spice. Chinese cinnamon is "in quills of varying length and about 1 Mm. or more in thickness; nearly deprived of the corky layer; yellowish-brown; outer surface somewhat rough; fracture nearly smooth; odor fragrant; taste sweet, and warmly aromatic." *U. S.*

Saigon cinnamon takes its name from Saigon, the capital of French Cochin-China. It is a thick

* For method of collection, see *P. J. Tr.*, Feb. 1890.

† For an account of the cultivation of *C. zeylanicum*, see *P. J. Tr.*, xi. 261; also one containing statistics and interesting notes on Chinese cassia in *P. J. Tr.*, 1898, 47.

cassia bark, which has come into European commerce, and is recognized for the first time by the U. S. P. 1890. It is officially described as "in quills about 15 Cm. long, and 10 to 15 Mm. in diameter, the bark 2 or 3 Mm. thick; outer surface gray or light grayish-brown with whitish patches, more or less rough from numerous warts and some transverse ridges and fine longitudinal wrinkles; the inner surface cinnamon-brown or dark brown, granular and slightly striate; fracture short, granular, in the outer layer cinnamon-colored, having near the cork numerous whitish striæ forming an almost uninterrupted line; odor fragrant; taste sweet, warmly aromatic, somewhat astringent." *U. S.* The odor of this cinnamon is fragrant, the taste is highly aromatic, markedly that of cinnamon, and, in the specimens that we have seen, only slightly astringent. It also occurs in commerce much broken, in which state it commands a somewhat smaller price than when in quills. The Saigon buds also are brought into the port of New York. The quality of Saigon cassia, as it is commonly termed in trade journals, is distinctly superior to that of other cassias, and the price which it commands much higher. It is obtained from the *Cinnamomum loureirii* of Nees, the *Laurus cinnamomum* of Loureiro. According to Siebold, the bark of the large branches is of inferior quality and is rejected; that from the smallest branches resembles the Ceylon cinnamon in thickness, but has a very pungent taste and smell, and is little esteemed; while the intermediate branches yield an excellent bark, about a line in thickness, which is even more highly valued than the cinnamon of Ceylon, and yields a sweeter and less pungent oil. (*Ann. der Pharm.*, xx. 280.)



Powdered cinnamon as found in commerce is often grossly adulterated; sugar, ground walnut-shells, and ground cinnamon-shells have been detected. (*Chem. and Drug.*, 1895, 867.) Drug millers sometimes add cassia buds to inferior grades of bark, siftings, etc., and powder the mixture; Pfister (*Forschungs Berichte*, i. 540) considers this addition an advantage to the low grade powder, for the reason that cassia buds contain a larger proportion of volatile oil.

The *Pharmacographia* gives the following tests for distinguishing powdered cassia from powdered cinnamon, and for recognizing the inferior varieties of cassia. Make a decoction of powdered cinnamon of known genuineness, and one of similar strength of the suspected powder; when cool and strained, test a fluidounce of each with one or two drops of tincture of iodine. A decoction of cinnamon is but little affected, but in that of cassia a deep blue-black tint is immediately produced. The cheap kinds of cassia known as *cassia vera* may be distinguished from the more valuable Chinese cassia as well as from cinnamon by their richness in mucilage; this can be extracted by cold water as a thick glairy liquid, giving dense ropy precipitates with corrosive sublimate or neutral acetate of lead, but not with alcohol.

Microscopic Structure. Ceylon cinnamon usually consists simply of liber, the outer coatings having been stripped off during its preparation for market. Three layers are distinguishable in the liber. "1. The external surface, which is composed of one to three rows of large thick-walled cells (Fig. 1), forming a coherent ring; it is only interrupted by bundles

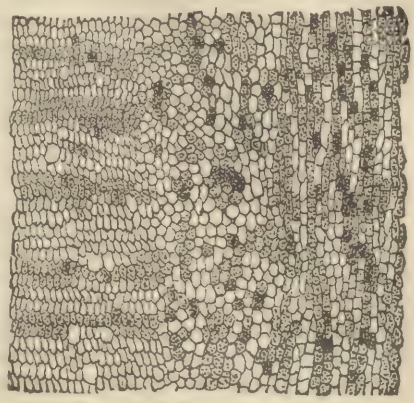


FIG. 1.—True Cinnamon, transverse section (very highly magnified).

Cassia Bark, longitudinal section.

of liber fibres, which are obvious even to the unaided eye. 2. The middle layer is built up of about 10 rows of parenchymatous thin-walled cells, interrupted by much larger cells containing

deposits of mucilage, while other cells not larger than those of the parenchyme itself are loaded with essential oil. 3. The innermost layer exhibits the same thin-walled but smaller cells, yet intersected by narrow somewhat darker medullary rays, and likewise interrupted by cells containing either mucilage or essential oil, instead of bundles of liber fibres. Fibres mostly isolated are scattered through the two inner layers, the parenchyme of which abounds in small starch granules accompanied by tannic matter. On a longitudinal section the length of the liber fibres becomes more evident, as well as oil-ducts and gum-ducts." (*Pharmacographia.*)

Cassia Bark, transverse section.

The coarser cassia bark, or *cassia lignea*, usually has some of the external or corky layer adherent to it, and always the parenchymatous mesophlœum or middle bark, but the liber constitutes the chief mass. Isolated liber fibres and thick-walled cells (stone-cells) are scattered even through the outer layers of a transverse section. In the middle zone they are numerous, but do not form a coherent sclerenchymatous ring as in Ceylon cinnamon. The innermost part of the liber shares the structural character of cinnamon, with differences due to age, as, for instance, the greater development of the medullary rays. Oil-cells and gum-ducts are likewise distributed in the parenchyme of the former. The finest cassia or Chinese cinnamon has the three layers described in Ceylon cinnamon, but is readily distinguished by the adherent outer parenchymatous and suberous layer.

Chemical Composition. According to the analysis of Vauquelin, cinnamon contains a peculiar volatile oil, tannin, mucilage, a coloring matter, an acid, and lignin. The tannin is of the variety which yields a greenish-black precipitate with the salts of iron. Thos. R. Thornton (*A. J. P.*, 1895, 400) has examined the tannin of *C. cassia*. He found it to amount to about 3·90 per cent., as an average of three different determinations on different samples. He found it impossible to extract the tannin by any one of several methods tried, and concludes that it either has the phlobophene (anhydride) character as it exists in the drug or acquires such character when brought into contact with water. Jas. A. Ferguson (1887), in the Laboratory of the Philadelphia College of Pharmacy, determined the ash of several samples of Ceylon cinnamon, finding an average of 4 per cent., while in powdered *cinnamon cassia* he found 2·8 and 2·5 per cent. (*A. J. P.*, 1887, 278, 279.) The oil obtained from the Cayenne cinnamon was found to be more biting than that from the Ceylonese. Bucholz found in 100 parts of *cassia lignea* 0·8 of volatile oil, 4·0 of resin, 14·6 of gummy extractive (probably including tannin), 64·3 of lignin and bassorin, and 16·3 of water, including loss. This aromatic yields its virtues wholly to alcohol, and less readily to water. At the temperature of boiling alcohol very little of the oil rises, and an extract prepared from the tincture retains, therefore, the aromatic properties. For an account of the volatile oil, see *Oleum Cinnamomi.*

Medical Properties and Uses. Cinnamon is among the most grateful and efficient of the aromatics. It is warm and cordial to the stomach, carminative, astringent, and, like most other substances of this class, more powerful as a local than as a general stimulant. It is seldom prescribed alone, though, when given in powder or infusion, it will sometimes allay nausea, check vomiting, and relieve flatulence. It is chiefly used as an adjuvant, and enters into a great number of official preparations. It is often employed in *diarrhœa*, in connection with chalk and astringents, and has recently been recommended as peculiarly efficacious in *menorrhagia.* Dose of powder, 10 grains to a scruple (0·65–1·3 Gm.).

COCA. U. S. (Br.) Coca.

(CŌ'CĄ.)

"The leaves of Erythroxylon Coca, Lamarck (nat. ord. Lineæ)." *U. S.* "The dried leaves of Erythroxylum Coca, Lam., and its varieties." *Br.*

Cocæ Folia, *Br.*, Coca Leaves; Erythroxylon, *Pharm.* 1880; Cuca; Feuilles de Coca,, *Fr.;* Cocablätter, *G.*

Gen. Ch. Calyx five-parted, at the base five-angular. *Styles* three, distinct to the base and not united into one. *De Candolle, Prodromus*, i. 573.

E. coca. Lam. *B. & T.* i. 40. Leaves ovate, areolate, membranaceous, branches squamous, pedicels lateral, aggregated in twos or threes, a little longer than the flower. *De C.**

According to the researches of Prof. H. H. Rusby, there are two distinct varieties or, perhaps, species of Erythroxylon Coca, one the Bolivian form, the other the Peruvian, which are distinguished by the fruits being much the larger in the Bolivian variety, whilst the leaves are much the larger in the Peruvian. The Bolivian drug† is the more highly esteemed in Peru. The coca, which grows wild in various parts of South America, is cultivated not only in its native country, but also in British India, in Ceylon, and in Java. The coca shrubs of India and Ceylon seem to be the offspring of plants originally sent out from Kew Garden, which plants were derived from seeds obtained from Huanuco, and have been considered by Dr. Morris as a distinct variety, to which he gives the name of *E. nova-granatense.* Java plants originally grown from seeds obtained from a Ghent firm are said to be so distinct in characteristics as to constitute a true variety, *sprucenanum.* They are probably, however, merely altered forms of *E. nova-granatense.* For figures, see *P. J. Tr.*, vol. xxi. Typical leaves of *E. coca*, Lamarck, do not occur in commerce. The commercial leaves (1898) are the Peruvian, yielded by *E. nova-granatense*, Morris; and the Bolivian, yielded by *E. bolivianum*, Burck. The coca plant, which is propagated from the seed in nurseries, begins to yield in eighteen months, and continues productive for half a century. The leaves, when mature, are carefully picked by hand so as to avoid breaking them or injuring the young buds,‡ are slowly dried in the sun, and are then packed in bags (*cestos*) holding from twenty-five to one hundred and fifty pounds each. They were in general use among the natives of Peru at the time of the conquest, and have continued to be much employed to the present time. It is affirmed that nearly ten million dollars' worth, or forty million pounds, are annually produced, some plantations yielding three or four harvests a year. For details as to method of cultivation, etc., see *Therap. Gazette*, Jan. 1886; also *Chem. and Drug.*, 1897, 182.

Properties. The leaves resemble in size and shape those of tea, being oval-oblong, pointed, two inches or more in length by somewhat over an inch in their greatest breadth, and furnished with short delicate footstalks; but they are not, like the tea-leaves, dentate, and are distinguished from most other leaves by a slightly curved line on each side of the midrib, running from the base to the apex. These lines are not ribs, but curves, which have been produced by the peculiar folding of the leaf in the bud. Good specimens are perfectly flat, of a fine green

* The commercial value of cocaine has led to the examination by Prof. Eykmann of Java, and Mr. Howard of Kew Gardens, of various species of the genus Erythroxylon, other than *E. coca:* in a number of species the alkaloid was found, but always in too small quantities for commercial purposes. (For details, see *P. J. Tr.*, Jan. 1889.)

† From time to time various cocas of commerce are spoken of as varieties known by the name of the cities in which the large commercial houses have their head-quarters, or of the districts in which the cocas have been grown. Such cocas are, however, not really commercial varieties, and change from time to time in their names and even characteristics. There appear to be at present (1893) in the American markets only two distinctly characterized cocas: the one known as Trujillo or Truxillo coca, coming from the department of La Libertad in Northern Peru; the other, the Huanuco coca, coming from Huanuco and Cuzco in South Central Peru. Bolivian coca does not seem to reach us in its acknowledged form.

Truxillo coca is composed of bright-colored, extremely thin, very fragile leaves, which are distinctly smaller, narrower, and more lanceolate than those of the Huanuco coca, and have the lateral lines very fine; owing to their lack of strength, the leaves are much broken, indeed in fragments, in the commercial samples. According to Prof. Rusby, this coca is yielded by the typical *E. coca*, but it is attributed by Hesse to *E. coca* var. *nova-granatense*. It is probably, therefore, similar to the coca produced in India, Ceylon, and Java, which has not reached this country commercially.

The leaves of the *Huanuco* or *Cuzco coca* are thick, indeed somewhat coriaceous, not much broken, from an inch to three inches in length. We have compared a large number of specimens of this coca with Bolivian coca, gathered in the province of Yungas near Coriaco, by Prof. H. H. Rusby or his assistant, and with other less authentic specimens of Bolivian coca. We can make out no difference between the Huanuco leaf and the coca leaf grown in Bolivia, and believe that the Huanuco coca is the product of *E. coca* var. *bolivianum*, grown in Peru.

The comparative value of cocas is a matter of great commercial importance. The South American coca is said to vary from 0·02 per cent. up to 1·02 per cent., or even more, in the yield of alkaloids, the average being, according to Hesse, in good specimens about 0·08 per cent. Messrs. Parke, Davis & Co., however, write us that in a very large number of chemical assays they have never been able to obtain more than 0·05 per cent. of cocaine out of any South American coca. It is possible that alkaloidal deterioration occurs during transportation. According to Warden, the alkaloidal yield of India coca varies from 0·36 to 1·67 per cent. The government chemists in Java report that the Java leaf contains over 2 per cent. of cocaine; but a sample obtained directly from Java by Parke, Davis & Co. yielded only 1·06 per cent. of total alkaloids. The total yield of alkaloids is not an exact criterion of the value of the leaves, because in some, and it is said especially in the Ceylon and Java cocas, cocaine constitutes only a small proportion of the total alkaloids. It is not possible to determine the alkaloidal value of a coca by its physical properties, so that at present the large manufacturers of cocaine buy the drug by assay.

It is interesting to note that Mr. C. J. H. Warden states (*P. J. Tr.*, May, 1888) that India coca can be distinguished by the peculiarities of its cocatannic acid.

‡ *Taja* is a peculiar disease of the coca plant, believed to be due to a fungus which results from wounding the twigs during careless picking of the leaves.

color; brown leaves should always be rejected as inferior. They have an agreeable odor resembling that of tea, and a peculiar taste, which, in decoction, becomes bitter and astringent. "Varying between ovate, lanceolate, and obovate-oblong, and from 2 to 5 or 7 Cm. in length; short-petiolate, entire, rather obtuse or emarginate at the apex, slightly reticulate on both sides, with a prominent midrib, and on each side of it a curved line running from base to apex; odor slight and tea-like; taste somewhat aromatic and bitter. When chewed, it temporarily benumbs the lips and tongue." *U. S.* "The midrib itself is prolonged into a minute horny apiculus, which, however, is frequently broken off. Most of the epidermal cells of the under surface are seen in transverse section to project in the form of small papillæ." *Br.* The leaves described by the U. S. P. are the Bolivian; the Peruvian leaves are shorter and narrower, are pale in color, and do not exhibit a prominent ridge above the midrib on the upper surface, nor such distinct curved lines on either side of the midrib on the under surface. Mildewed leaves should not be accepted.

Chemical Constitution. In 1853, Wackenroder demonstrated the existence of tannic acid in coca leaves; and in 1859, M. Stanislaus Martin found in them a peculiar bitter principle, resin, tannin, an aromatic principle, extractive, chlorophyll, a substance analogous to theine, and salts of lime. Previous to this (1855) Gardeke had isolated the crystalline alkaloid and given it the name of *erythroxyline*. Dr. Albert Niemann, of Goslar, made the first thorough investigation of the leaves, and gave to the alkaloid the name it now usually bears of *cocaine*.* The following was his process. The leaves were exhausted with 85-per-cent. alcohol acidulated with 2 per cent. of sulphuric acid; the tincture was treated with milk of lime and filtered; the filtrate was neutralized with sulphuric acid, and the alcohol distilled off. The syrupy residue was treated with water to separate resin, and then precipitated by sodium carbonate. The deposited matter was exhausted by ether, and the ethereal solution, after most of the ether had been distilled, was allowed to evaporate spontaneously. The cocaine was thus obtained in colorless crystals, mixed with a yellowish-brown matter of a disagreeable odor, which was separated by washing with cold alcohol. Dr. Squibb's process for cocaine and its hydrochlorate is as follows. Coarsely ground coca leaves are repercolated with an aqueous five-per-cent. solution of sulphuric acid, and a very dense, slightly acid percolate is obtained; this is thoroughly agitated with pure coal oil and an excess of sodium carbonate; the liberated alkaloid is retained by the coal oil, and is nearly free from coloring matter; the oily solution is then agitated with acidulated water, and again precipitated by sodium carbonate in the presence of ether. The ethereal solution of cocaine is treated with diluted hydrochloric acid fractionally, and the nearly colorless solutions of cocaine hydrochlorate are cautiously evaporated in shallow porcelain pans almost to dryness. The product is in the form of a white, crystalline, granular powder, and is a nearly pure anhydrous salt. (*Ephemeris*, 1887, 906.) For Henrique's process, see *Proc. A. P. A.*, 1895, 999. Pure cocaine is in colorless, transparent prisms, inodorous, of a bitterish taste, soluble in 704 parts of cold water, more soluble in alcohol, and freely so in ether. The solution has an alkaline reaction and a bitterish taste, leaving a peculiar numbness on the tongue. The alkaloid melts at 97·7° C. (208° F.), and on cooling congeals into a transparent mass, which gradually becomes crystalline. Heated above this point it changes color, and is decomposed. It is inflammable, burning with a bright flame, and leaving charcoal. With the acids it forms soluble and crystallizable salts, which are more bitter than the alkaloid itself. The formula is $C_{17}H_{21}NO_4$. (See *Cocaina*, p. 428.) Dr. Niemann also obtained wax, a variety of tannic acid (*cocatannic acid*), and a concrete volatile odorous substance. The presence of *hygrine* in coca leaves is not confirmed. M. Lossen has examined cocaine, and ascertained that when heated with hydrochloric acid it splits into benzoic acid, methyl alcohol, and a new base which he calls *ecgonine*, of which the formula is $C_9H_{15}NO_3$. Cocaine is, therefore, ascertained to be *methylbenzoylecgonine*, $CH_3.N\begin{cases} C_5H_7 \\ CH(OC_7H_5O)CH_2.CO_2CH_3 \end{cases}$, while *benzoylecgonine*, which

* *Benzoyl ψ Tropein. Tropacocaine*, $C_8H_{14}NO.C_7H_5O$. This compound, belonging chemically to the class of Tropeines (see Atropine, p. 242), was isolated by Giesel from a narrow-leaved coca plant from Java. (*Ber. der Chem. Gesell.*, xxiv. p. 2336.) It is obtained as an oil, which when quite dry solidifies in radiating crystals, melting at 49° C. It has a strong alkaline reaction, and is easily soluble in alcohol, ether, chloroform, benzene, and petroleum spirit. It is decomposed by heating with hydrochloric acid into benzoic acid and pseudo-tropine, $C_8H_{15}NO$.

Tropacocaine has been studied by Dr. Arthur P. Chadbourne, who finds that its general action on the system resembles that of cocaine, and that although it is capable of causing death by paralyzing the respiratory centres, and is also in overdose a powerful cardiac depressant, it nevertheless is very much less poisonous than cocaine. On the other hand, Chadbourne's experiments and the clinical researches of Prof. Schweigger seem to show that tropacocaine as a local anæsthetic is much more powerful and prompt in its action than cocaine. Notwithstanding various favorable reports, tropacocaine has, however, failed to come into use as a local anæsthetic.

also occurs in coca leaves, is $C_{16}H_{19}NO_4$. Cocaine is thus seen to be the methyl ether of this latter. The fundamental base, ecgonine, $CH_3.N\begin{cases} C_5H_7 \\ CH(OH).CH_2.COOH \end{cases}$, forms monoclinic prisms melting at 198° C.* A considerable number of closely allied alkaloids, all of which appear to be derivatives of ecgonine, are found in the leaves of *Erythroxylon coca*. The following list is given in Allen (*Commerc. Org. Anal.*, 2d ed., vol. iii., part ii., 271), on the authority of Paul and Cownley:

$C_9H_{17}NO_2$, *Anhydro-ecgonine.*
$C_9H_{15}NO_3$, *Ecgonine.*
$C_{16}H_{19}NO_4$, *Benzoyl-ecgonine.*
$C_{17}H_{21}NO_4$, *Benzoyl-ecgonine methyl ester (cocaine).*
$C_{18}H_{21}NO_4$, *Cinnamyl-ecgonine.*
$C_{19}H_{23}NO_4$, *Cinnamyl-ecgonine methyl ester.*
$C_{38}H_{46}N_2O_8$, *Cocayl-ecgonine methyl ester (cocamine).*
$C_{40}H_{50}N_2O_8$, *Homo-cocamine.*
$C_{17}H_{19}NO_2$, *Benzoyl-pseudotropine (tropsin).*

With the exception of ecgonine and anhydro-ecgonine, all of the bodies in the foregoing list are saponifiable, splitting up when heated to from 80° to 100° C. with hydrochloric acid, or when boiled with alcoholic potash.

As the separation of cocaine from the accompanying alkaloids and products of hydrolysis is difficult, Liebermann (*Berichte*, xxi. 3196) has proposed a synthetic method which avoids these difficulties and at the same time utilizes the amorphous bi-products. The mixed bases are boiled with hydrochloric acid, whereby they all suffer hydrolysis with formation of ecgonine; then, by passing dry hydrochloric acid into a solution of ecgonine hydrochloride in methyl alcohol, the hydrochloride of ecgonine methyl ester is formed, which on concentrating the alcoholic solution crystallizes out in prisms. Cocaine is formed when this compound is heated on the water-bath with an equal weight of benzoyl chloride until the mixture becomes homogeneous and the evolution of hydrochloric acid ceases. The melted mass is poured into water and separated from the insoluble benzoic acid, when the cocaine is precipitated by ammonia and recrystallized from alcohol. The tannin of coca leaves strikes a green-black with ferric salts, and has received the name of *cocatannic acid*. Romburgh has detected traces of *methyl salicylate* in the distillate from coca. (*Chem. Zeit.*, 1895, 130.) For methods of assaying coca leaves, see Lyons, *Chicago Pharmacist*, 1885, Sept.; Squibb, *Ephemeris*, 1887; Dohme, *Proc. A. P. A.*, 1893, 159; Prescott, *Organic Analysis; Proc. A. P. A.*, 1895, 268; *P. J. Tr.*, 1896.

Medical Properties. As a nerve stimulant, coca has been used immemorially by the Peruvian and Bolivian natives. In 1853, Dr. Weddell stated that it produces a gently excitant effect, with an indisposition to sleep, in these respects resembling tea and coffee; also that it will support the strength for a considerable time in the absence of food, but does not supply the place of nutriment, and probably in this respect also acts like the two substances referred to. The Indians, while chewing it, mixed with some alkaline substance, as the ashes of certain plants, or lime, pass whole days in travelling or working without food. It is, however, clearly proved that these leaves do not take the place of nutriment, but simply put off the sense of fatigue and hunger, the Indian making up at his evening meal for the day's abstinence. It is probable that they prevent hunger simply by their local benumbing influence upon the nerves of the stomach. Their moderate habitual use does not seem to be injurious, but the habit is said readily to grow upon the person, and finally the inveterate excessive coca-chewer can be recognized by his uncertain step, general apathy, sunken eyes surrounded by deep purple aureoles, trembling lips, green and crusted teeth, and excessively fetid breath, with peculiar blackness about the corners of the mouth. An incurable insomnia is apt to be developed, emaciation becomes extreme, dropsy appears, and even death results in a condition of general marasmus. When coca is taken in a single large dose it produces a condition of peculiar physical beatitude and calm, followed by a sensation of excessive power, which is affirmed to be accompanied by a real increase of physical ability. Dr. Mantegazza took in the course of two hours about 900 grains of the coca leaf, with the result of great increase in the number of the heart-beats, and a condition of intoxication resembling that produced by hasheesh. He was possessed by a feeling of intense joyousness, while a succession of visions and phantasma-

* *Cocaine Homologues.* M. Poulsson has physiologically investigated compounds in which the radical methyl, ethyl, and propyl are substituted for the *benzoic acid*, and to which he has given the names of *homométhincocaïne*, *homoéthincocaïne*, and *homopropincocaïne*. He finds that these substances act upon the animal organization like ordinary cocaine. On the other hand, *cocaylbenzoyloxyacetic acid* and *benzoylhomoecgonine* do not have the physiological action of cocaine. M. Ehrlich has found that benzoylecgonine and methylecgonine are twenty times less poisonous than cocaine, whilst the derivatives of cocaine obtained by substituting "in the benzoylecgonine other alcoholic radicals than methyl for the hydrogen of the carboxyl group, *cocaéthyline*, *cocopropyline*, *isopropyline*, and *cocoïsobutyline*," are as toxic as cocaine and act like it. (*Gaz. Méd. de Paris*, Oct. 1890.)

goria, most brilliant in form and color, trooped rapidly before his eyes. He then passed into a condition of delirious excitement, which was succeeded by a deep sleep lasting three hours.

The symptoms which have just been detailed are those which have been recorded by various writers as produced by the coca leaf in the land of its growth, and especially upon the natives of the country. The action of the alkaloid cocaine, and even of the drug coca, upon North Americans and Europeans, differs essentially from these effects.* Numerous cases of poisoning have occurred from the alkaloid: P. Mannheim has collected as many as ninety-nine. (*Cleveland Med. Gaz.*, Sept. 1891.) In mild cases the ordinary symptoms have been great restlessness and nervous excitement, but no sense of beatitude, rather a condition of fear and terror. With this state come usually distinctly accelerated pulse, increased frequency of respiration, and, perchance, muscular twitchings or even mild convulsions. In the more severe cases of poisoning the symptoms vary; sometimes there have been nausea, vomiting, rapid almost imperceptible pulse, great perspiration, collapse with or without loss of consciousness; in other cases the pulse has been slow and feeble, and sometimes pronounced cyanosis, with slow or almost arrested respiration, has been the most alarming manifestation. The pupils are usually dilated, but are reported in some cases as "contracted." After very large doses convulsions usually occur; they are often violent and epileptiform; not rarely, at times at least they are partial, and in many cases opisthotonos has been pronounced. Consciousness rarely escapes; usually it is lost, but sometimes it is merged into a mania with hallucinations and delusions, which mania may become violent and even homicidal, as in a case reported by Mattison. Poisoning has followed both the internal administration and the local uses of the alkaloid. The occasional over-effects of small doses are quite remarkable: thus, four drops of a two-per-cent. solution in the eye produced in an old lady intoxication which persisted four days; eight drops of a ten-per-cent. solution in the eye of a girl of twelve years caused violent poisoning; and even one drop of a one-per-cent. solution in the eye of a child fourteen years old is said to have been followed by violent symptoms. A number of cases are on record in which one grain of the alkaloid given hypodermically has caused very severe fainting. Death is reported in several cases from the local use of the remedy, and twelve drops of a four-per-cent. solution given hypodermically to a girl of eleven caused death in forty seconds. On the other hand, large doses have been recovered from: twenty-two grains by the mouth, ten grains hypodermically, five grains hypodermically, six grains hypodermically. (See H. C. Wood's *Therapeutics.*)

Although cocaine has been used an enormous number of times as a local application without much stint, and although doses have been given of two grains, it is evidently not safe to apply more than three-quarters of a grain to the mucous membranes of an adult, or to give more than the same amount at a dose, or to use hypodermically more than half a grain.

Cocaine is a cerebral stimulant, producing peculiar mental excitement, ending after large toxic doses in narcosis, with epileptiform convulsions, which are probably of cerebral origin. In the poisoning there is at first increased reflex activity, followed by paralysis of voluntary motion and of reflex activity, which are chiefly due to a direct action upon the spinal cord, the sensory side of the cord being probably more sensitive to the drug than the motor side. Toxic doses depress and finally paralyze the sensory nerves, and in a much less degree the motor nerves. The action of cocaine upon the circulation is pronounced, though less than its influence upon the nervous system. The arterial pressure is increased, which increase is probably the result, first, of a stimulation of the vaso-motor centres in the medulla oblongata; second, of a stimulant action upon the heart; and, thirdly and more doubtfully, of a slight stimulation of the muscle-fibres in the vessel walls. The increased action of the heart is probably due, as Prof. E. T. Reichert has made out, to a depressing influence on the cardio-inhibitory apparatus, both centric and peripheral, causing an acceleration of the pulse. It is probable, however, that the alkaloid acts directly upon the cardiac muscle, or intra-cardiac nerves, so as to increase the energy of contraction. Toxic doses of cocaine produce sooner or later a fall of the arterial pressure, which appears to be the result of a direct action upon the heart and the vaso-motor system. Upon striated muscles cocaine appears to have a peculiar though very feeble action,

* The reason of this difference is not evident. Prof. Rusby found that coca triturated with Mayer's reagent both before and after exportation gave evidence of a much larger percentage of the alkaloid before the exportation. He believes that during exportation the leaves lose largely of some volatile substance, probably hygrine. According to Hesse, however, hygrine is not an alkaloid of coca, but is a foreign body due to impurities in the reagents employed. (*P. J. Tr.*, vol. xx. p. 1135, 1891; also vol. xxii. p. 102.) Dr. H. C. Wood made some not very thorough tests with preparations of coca made in South America from the fresh drug under the supervision of Prof. Rusby and furnished by Parke, Davis & Co., and was not able to detect any difference between their action and that of the parallel preparations made in this country. At present it seems probable that the difference of action under discussion is due simply to difference of race, precisely as with the effects of hasheesh upon Asiatics and upon Europeans.

which is not manifested during poisoning by it. It has been asserted that cocaine acts as a powerful diuretic, but the drift of present evidence is to show that it has no definite influence upon the amount of urine secreted; what evidence is available indicates that it decreases the elimination of urea. Dropped into the eye, cocaine actively dilates the pupil without increasing the intra-ocular pressure or completely paralyzing the accommodation. It is a powerful stimulant to the respiratory centres, increasing the rapidity and fulness of the respirations, but if the dose be sufficiently large it after a time causes the respirations to become very shallow, and finally paralyzes the respiratory centres. Moderate doses are said to increase, large doses to paralyze, peristalsis.

The stimulant effect of coca has led to its extensive use in *melancholia*, *neurasthenia*, *hysteria*, and allied disorders. The results obtained, however, have not been what were expected. Almost all clinicians agree that in melancholia no good whatever is achieved, and that in neurasthenia and hysteria the drug, unless given in small doses, acts deleteriously, although in some cases the fluid extract of coca or a coca wine seems to be of service for a time in stimulating the digestion and, to some slight extent, the general nervous system. Locally applied, cocaine is a very distinct and certain anæsthetic, acting, according to the observations of Von Anrep, upon the nerves of special sense as well as upon those of common sensibility. Cocaine penetrates mucous membranes readily, but is not able to pass through the skin, and when given hypodermically so rapidly diffuses itself that its local anæsthetic influence is very fugacious unless the circulation in the part be controlled by mechanical means. Injected so as to come immediately in contact with the large nerve-trunk, it is capable of producing temporary anæsthesia over the whole distribution of the nerve. When applied in concentrated solution to the mucous membranes, it produces at once a marked pallor, which is probably due to a powerful constriction of the blood-vessels caused by a direct action upon their muscle-fibres. In practical medicine cocaine is used for its local effects in benumbing sensibility and relieving pain in all mucous tracts that can be reached by the surgeon. When prescribed in an ointment, soluble salts of cocaine should be used, and sufficient water directed to prevent crystallization. In *burns*, *painful ulcers*, *fissures of the anus*, etc., cocaine is a very valuable remedy. It is also employed with success in various local inflammations of the mucous membranes, subduing nervous irritability, and by its constringing influence relieving or even curing acute inflammations. Thus, a mixture of cocaine and bismuth will often arrest an acute coryza. In *hay fever*, in the *irritated sore throat* of advanced phthisis, in *chronic laryngitis*, in inflamed *hemorrhoids*, and even in *bronchitis* with excessive cough, it often may be locally applied with advantage. The fugaciousness of its effects makes it a valuable mydriatic when it is desired simply to examine the eye-ground. The strength of the solution for local application may vary from 2 to 10 per cent., according to the effects desired. In *coryza* and *hay fever* bougies made with cacao butter, containing each from one-quarter to one-half grain of cocaine, are often very efficacious. In internal medicine cocaine is valuable for its local influence upon the gastro-intestinal tract in excessive *vomiting*, and also in *serous diarrhœa*. The habitual use of cocaine as a stimulant has in many cases led to the formation of the cocaine habit, with the production of ill health, accompanied by headache, malaise, insomnia, prostration, often faintness, vertigo, and deterioration of the cerebral function. A symptom which is said to be characteristic of chronic cocaine poisoning was first described by Magnan, and is known as Magnan's symptom. It consists of an hallucination of common sensation, the feeling that some foreign body is under the skin, with an often consequent complaint that grains of sand, worms, or other foreign body are situated in the position named. The immediate withdrawal of the cocaine in cases of the cocaine habit is not usually followed by any serious danger to life: symptoms that may arise are to be met on general principles.

The dose of coca is from one-half to one drachm (1·95–3·9 Gm.). If given in infusion the leaves should be swallowed, as it is by no means certain that they yield their virtues to water. The fluid extract is now official, and is a very eligible preparation; a *tincture of coca*, made in the proportion of one part in five of diluted alcohol, and a *wine of coca*, one in ten, would also be efficient. The *elixir of coca*, as usually dispensed, is too weak to be of much value. (See PART II.)

COCAINA. Br. Cocaine.

(CŌ-CA-Ī'NA.)

"An alkaloid, $C_{17}H_{21}NO_4$, obtained from the leaves of Erythroxylum Coca, Lam., and its varieties." *Br.*

The processes for making this alkaloid will be found under *Coca*. Owing to the small yield,

it is found more profitable to manufacture cocaine in South America and export it, thus saving the expense of transporting the bulky coca leaves abroad. The British Pharmacopœia gives the following description and tests: "Colorless monoclinic prisms which have a bitter taste followed by a sensation of tingling and numbness. It melts at 204·8° to 208·4° F. (96° to 98° C.). Almost insoluble in *water*, insoluble in *glycerin*, soluble in 10 parts of *alcohol* (90 per cent.), in 4 parts of *ether*, in ½ part of *chloroform*, in 12 parts of *olive oil*, and in 14 parts of *oil of turpentine*. Its solution in *water* acidulated with *hydrochloric acid*, and the dry salt obtained on evaporating this solution, afford the reactions mentioned under 'Cocainæ Hydrochloridum.' Its solution in *water* acidulated with *nitric acid* yields no reaction with the tests for chlorides or sulphates."

Medical Properties. (See p. 428.) Various salts of the alkaloid have been used in medicine. *Cocaine hydriodide* ($C_{17}H_{21}NO_4HI$), which occurs in colorless crystals only moderately soluble in water, has been especially recommended by R. Marcus as being suitable for use by cataphoresis for the production of anæsthesia.

COCAINÆ HYDROCHLORAS. U. S. (Br.) Cocaine Hydrochlorate.

$C_{17}H_{21}NO_4$, HCl; 338·71. (CŌ-CA-Ī'NÆ HŸ-DRO-ȻHLŌ'RĂS.) $C_{17}H_{21}NO_4$, HCl; 339·5.

"The hydrochlorate of an alkaloid obtained from Coca." *U. S.* "The hydrochloride, $C_{17}H_{21}NO_4$,HCl, of an alkaloid obtained from the leaves of Erythroxylum Coca, Lam., and its varieties." *Br.*

Cocainæ Hydrochloridum, *Br.*, Cocaine Hydrochloride, Hydrochlorate of Cocaine.

The British Pharmacopœia gives the following tests: "It melts at 356° to 366·8° F. (180° to 186° C.). Soluble in half its weight of cold *water*, forming a clear and colorless solution, neutral to *litmus*, and in four times its weight of *alcohol* (90 per cent.) or of *glycerin*. It is insoluble in *olive oil* and almost insoluble in *ether*. It affords a yellow precipitate with *solution of auric chloride;* a white precipitate with *solution of ammonium carbonate*, and also with *solution of borax*. It dissolves without color in cold *sulphuric* or *nitric acid*, but chars with hot *sulphuric acid*, evolving an agreeable odor, and yielding a crystalline sublimate of benzoic acid. Its aqueous solution yields with *solution of potassium hydroxide* a white precipitate soluble in *alcohol* or *ether*, with *solution of picric acid* a yellow precipitate becoming crystalline on standing, with *test-solution of mercuric chloride* slightly acidulated with *hydrochloric acid*, a white precipitate soluble in hot *water*. Moistened with *nitric acid*, the mixture evaporated to dryness, and a drop of *alcoholic solution of potassium hydroxide* added, a characteristic odor is evolved more or less recalling that of peppermint. A solution containing not less than 1 per cent. gives with excess of *solution of potassium permanganate* a copious red precipitate which does not change color within an hour (absence of cinnamyl cocaine and cocamine or other products derived from cocaine). 0·1 gramme dissolved in 100 cubic centimetres of *water* and 0·25 cubic centimetre of *solution of ammonia* added, affords a clear solution, from which a crystalline deposit should gradually separate on stirring (limit of amorphous alkaloid). It should not afford more than the slightest reactions with the tests for sulphates. Dried for twenty minutes at 204° to 212° F. (95·6° to 100° C.) it should not lose more than 1 per cent. of moisture."

"It may be obtained by agitating with ether an aqueous solution of an acidulated alcoholic extract, made alkaline with carbonate of sodium; separating and evaporating the ethereal liquid; purifying the product by repeating the treatment with acidulated water, carbonate of sodium, and ether; decolorizing; neutralizing with hydrochloric acid, and recrystallizing." *Br.* (1885). For other processes, see *Coca*.

Properties. "Colorless, transparent crystals, or a white, crystalline powder, without odor, of a saline, slightly bitter taste and producing upon the tongue a tingling sensation followed by numbness of some minutes' duration. Permanent in the air. Soluble, at 15° C. (59° F.), in 0·48 part of water, and in 3·5 parts of alcohol; very soluble in boiling water, and in boiling alcohol; also soluble in 2800 parts of ether, or in 17 parts of chloroform. On heating a small quantity of the powdered salt for twenty minutes at a temperature of 100° C. (212° F.), it should not suffer any material loss (absence of *water of crystallization*). The prolonged application of heat to the salt, or to its solution, induces decomposition. At 193° C. (379·4° F.)* the

* J. M. Francis believes that, owing to the ready decomposition of the salt before the melting point is reached, much variation must be expected in these figures. (*Bull. Pharm.*, 1893, 541.)

salt melts with partial sublimation, forming a light brownish-yellow liquid. When ignited, it is consumed without leaving a residue. The salt is neutral to litmus paper. On adding 5 drops of a 5-per-cent. solution of chromic acid to 5 C.c. of a 2-per-cent. solution of Cocaine Hydrochlorate, a yellow precipitate is produced which redissolves on shaking; on now adding 1 C.c. of hydrochloric acid, a permanent, orange-yellow precipitate will be formed. If a small quantity of the salt be rubbed, with a glass rod, on a dry, white porcelain surface, with an equal bulk of mercurous chloride, and the mixture then breathed upon, it will acquire a dark gray or grayish-black color. The aqueous solution of the salt yields, with silver nitrate test-solution, a white precipitate insoluble in nitric acid. The addition of sulphuric or nitric acid to the salt, at the ordinary temperature, should develop no color. If 1 drop of a mixture of 1 volume of potassium permanganate decinormal volumetric solution and 2 volumes of water be added to 5 C.c. of a 2-per-cent. solution of Cocaine Hydrochlorate mixed with 3 drops of diluted sulphuric acid and contained in a small, clean, glass-stoppered vial, the pink tint produced by the permanganate should not entirely disappear within half an hour (absence of *cinnamyl-cocaine* and some *other bases derived from Coca*)." *U. S.*

For physiological and medical properties, see *Coca*. The dose of the salts of cocaine may be set down at from one-quarter to one grain (0·016 to 0·065 Gm.).

COCCUS. U. S., Br. Cochineal.

(cŏc'cŭs.)

"The dried female of Coccus cacti, Linné (class, Insecta; order, Hemiptera)." *U. S.* "The dried fecundated female insect, Coccus Cacti, Linn., reared on Nopalea coccinellifera, Salm-Dyck, and on other species of Nopalea." *Br.*

Coccionella, *P. C.;* Cochenille, *Fr., G.;* Scharlachwurm, *G.;* Cocciniglia, *It.;* Cochinilla, *Sp.*

The coccus is a genus of hemipterous insects, having the snout or rostrum in the breast, the antennæ filiform, and the posterior part of the abdomen furnished with bristles. The male has two erect wings, the female is wingless. The *C. cacti* is characterized by its depressed, downy, transversely wrinkled body, its purplish abdomen, its short and black legs, and its subulate antennæ, which are about one-third of the length of the body. (*Rees's Cyclopædia.*) Another species, *C. ilicis*, which inhabits a species of oak, is collected in the mountainous parts of the Morea, in Greece, and used as a dye-stuff in the East, under the name of *kermes*, *chermes*, or *alkermes*. The dried insects are nearly globular, smooth, about the size of a pea, and of a reddish-brown color. They yield a carmine-colored powder, and, with a salt of tin, a fine scarlet-red dye. The *Coccus cacti* is found wild in Mexico and Central America, inhabiting different species of Cactus and allied genera of plants, and is said to have been discovered also in some of the West India islands and in the southern parts of the United States. In Mexico, particularly in the provinces of Oaxaca and Guerrero, it is an important object of culture. The Indians form plantations of the *nopal* (*Nopalea coccinellifera*, Salm, formerly *Opuntia cochinillifera*, Mills), upon which the insect feeds and propagates. During the rainy season, a number of the females are preserved under cover, upon the branches of the plant, and, after the cessation of the rains, are distributed upon the plants without. They perish quickly after having deposited their eggs. These, hatched by the heat of the sun, give origin to innumerable minute insects, which spread themselves over the plant. The males, of which, according to Mr. Ellis, the proportion is not greater than one to one hundred or two hundred females, being provided with wings and very active, approach and fecundate the latter. After this period, the females, which before moved about, attach themselves to the leaves, and increase rapidly in size; so that, in the end, their legs, antennæ, and probosces are scarcely discoverable, and they appear more like excrescences on the plant than distinct animated beings. They are now gathered for use, by detaching them by means of a blunt knife, a quill, or a feather; a few being left to continue the race. They are destroyed either by dipping them enclosed in a bag into boiling water or by the heat of a stove. In the former case they are subsequently dried in the sun. The males, which are much smaller than the full-grown females, are not collected. It is said that of the wild insect there are six generations every year, furnishing an equal number of crops; but the domestic is collected only three times annually, the propagation being suspended during the rainy season, in consequence of the inability of the insect to support the inclemency of the weather. The insect has been taken from Mexico to the Canary Islands; and very large quantities of cochineal have been delivered

to commerce from the island of Teneriffe.* Its culture is said to have proved successful in Java and Algeria, but unprofitable in Spain.†

Cochineal is defined in the U. S. Pharmacopœia as follows: "About 5 Mm. long; of a purplish-gray or purplish-black color; somewhat oblong and angular in outline; flat or concave beneath; convex above; transversely wrinkled; easily pulverizable, yielding a dark red powder. Odor faint; taste slightly bitterish. Cochineal contains a red coloring matter soluble in water, alcohol, or water of ammonia, slightly soluble in ether, insoluble in fixed and volatile oils. On macerating Cochineal in water, it swells up, but no insoluble powder should be separated. When completely incinerated, Cochineal should leave not more than 5 per cent. of ash."

As found in commerce, the finer cochineal, *grana fina* of Spanish commerce, is in irregularly circular or oval, somewhat angular grains, about one-eighth of an inch in diameter, convex on one side, concave or flat on the other, and marked with several transverse wrinkles. Two varieties of this kind of cochineal are known to the druggist, distinguished by their external appearance. One is of a reddish-gray color, formed by an intermixture of the dark color of the insect with the whiteness of a powder by which it is almost covered, and with patches of a rosy tinge irregularly interspersed. From its diversified appearance, it is called by the Spaniards *cochinilla jaspeada*. It is the variety commonly found in commerce. The other, *cochinilla renegrida*, or *grana nigra*, is dark-colored, almost black, with only a minute quantity of the whitish powder between the wrinkles. The two are distinguished in our markets by the names of *silver grains* and *black grains*. Some suppose the difference to arise from the mode of preparation: the gray cochineal consisting of the insects destroyed by a dry heat; the black, of those destroyed by hot water, which removes the external whitish powder; it is also said that cochineal is blackened by placing the insects with black sand in a bag and swinging backward and forward until some of the juice exudes. According to Mr. Faber, who derived his information from a merchant residing in the neighborhood where the cochineal is collected, the silver grains consist of the impregnated female just before she has laid her eggs; the black, of the female after the eggs have been laid and hatched. (*A. J. P.*, xviii. 47.) There is little or no difference in their quality.‡ Another and much inferior variety is the *grana sylvestra*, or wild cochineal, consisting partly of very small separate insects, partly of roundish or oval masses, which exhibit, under the microscope, minute and apparently new-born insects, enclosed in a white or reddish cotton-like substance. It is scarcely known in our drug market.

Cochineal has a faint heavy odor and a bitter slightly acidulous taste. Its powder is of a purplish-carmine color, tingeing the saliva intensely red. According to Pelletier and Caventou, it consists of a peculiar coloring principle, a peculiar animal matter constituting the skeleton of the insect, stearin, olein, an odorous fatty acid, and various salts. Tyrosin has also been found by De la Rue, and its presence in cochineal recently confirmed by Von Miller and Rohde. (*Ber.*, xxvi., 2660.) It was also analyzed by John, who called the coloring principle *cochinilin*. It is, however, universally known now as *carminic acid*. Hlasiwetz and Grabowski (*Ann. Chem. und Ph.*, 141, 329) gave it the formula $C_{17}H_{18}O_{10}$, and considered it to be a glucoside, which was decomposed by boiling with diluted sulphuric acid into a non-fermentable sugar and *carmine red*, $C_{11}H_{12}O_7$. The incorrectness of this view of its composition has, however, been demonstrated by Von Miller and Rohde (*loc. cit.*), who have shown that the purified carminic acid is a dioxymethyl-*a*-naphthoquinone of the formula $C_{11}H_{12}O_6 + 2H_2O$, and that the carmine red is identical with it. Schunk and Marchlewski (*Ber.*, xxvii., 2979) have confirmed these results of Von Miller and Rohde, and have shown that the reason that the carminic acid as freshly extracted from the cochineal gave the apparent glucoside reaction was that it is impure. They prepared the pure crystallized carminic acid, its anilide, and identified its character as a naphthoquinone derivative. It shows no sharp melting point, beginning to decompose at 130° C. Carminic acid is of a brilliant purple-red color, unalterable in dry air, is

* Various species of Opuntia are adapted to the support of the cochineal insect, especially those which are very juicy, with few thorns and a thick skin. It is the *O. ficus indica* which is chiefly cultivated in Teneriffe, the dry but hot climate of which is peculiarly adapted to the growth both of the plant and the insect. For an account of the mode of rearing the cochineal insect in the Canary Islands, see *P. J. Tr.*, Sept. 1871; in Central America, see *A. J. P.*, 1873, 30; *N. R.*, 1880, 175; in Guatemala, see *Pharm. Era*, 1893, 227.

† In Asia Minor, in the vicinity of Oushak, are great quantities of an insect, closely resembling the Coccus cacti, which feeds on a species of Cistus; but it is unknown whether any portion has been introduced into general commerce. (*A. J. P.*, xxxv. 455.)

‡ *Cake cochineal* is the name given to a variety of the drug produced in the Argentine Republic. A specimen examined by Dr. Stark was in flat cakes about a quarter of an inch thick, and, under the microscope, was seen to consist chiefly of the cochineal insect, mixed with small portions of the thorns and epidermis of the cactus, in consequence of careless gathering. It is inferior for dyeing purposes to the ordinary variety. (*P. J. Tr.*, xiv. 346.)

very soluble in water, soluble in cold and more so in boiling alcohol, insoluble in ether, and without nitrogen. It is obtained by macerating cochineal in ether, and treating the residue with successive portions of boiling alcohol, which on cooling deposits a part of the carminic acid, and yields the remainder by spontaneous evaporation. It may be freed from a small proportion of adhering fatty matter by dissolving it in alcohol of 40° Baumé and then adding an equal quantity of ether. The pure carminic acid is deposited in the course of a few days. Chlorine readily destroys the carminic acid, and nascent hydrogen reduces it to a leuco body, which again becomes red on exposure to the air. Prof. Liebermann found that the coating of the silver cochineal consisted of a peculiar wax, which he named *coccerin*, $C_{30}H_{60}(C_{31}H_{61}O_3)_2$; this is soluble in benzene, but nearly insoluble in ether. (*P. J. Tr.*, 1885, 186; from *Berichte.*) The watery infusion of cochineal is of a violet-crimson color, which is brightened by the acids and deepened by the alkalies. The coloring matter is readily precipitated. The salts of zinc, bismuth, and nickel produce a lilac precipitate, and those of iron a dark purple approaching to black. The salts of tin, especially the nitrate and the chloride, precipitate the coloring matter of a brilliant scarlet, and form the basis of those splendid scarlet and crimson dyes which have rendered cochineal so valuable in the arts. With alumina the coloring matter forms the pigment called *lake.* The finest lakes are obtained by mixing the decoction of cochineal with freshly-prepared gelatinous alumina. The pigment called *carmine* is the coloring matter of cochineal precipitated from the decoction by acids, the salts of tin, etc., or by animal gelatin, and when properly made is of the most intense and brilliant scarlet. Cochineal-carmine requires for its production a decoction of cochineal itself, and not of carminic acid, the nitrogenized matters being essential to its formation. Liebermann (*Ber. der Chem. Gesell.*, xviii. p. 1971) considers cochineal carmine to be no ordinary compound of a coloring matter with alumina, but to be an alumina albuminate of the carmine coloring matter comparable in some respects to the product from alizarin and alumina with "Turkey-red oil." (See *Chem. and Drug.*, 1893, 199; *Zeitschr. f. Angewandte Chem.*, 1894.) J. J. Hess proved that if fatty matters found in cochineal were removed by treatment with alcohol, a much more brilliant carmine could be produced. He found in Guatemala cochineal 17 per cent. of a crystalline stearopten, in Java cochineal 7 per cent., and in Canary cochineal 18 per cent. (Dingler, *P. J. Tr.*, 235, 88; *N. R.*, 1880, 338.) The degree of coloring power in cochineal may be approximately measured by the decolorizing effect produced by solution of potassium permanganate. For a method of applying this process, the reader is referred to a paper by J. M. Merrick, of Boston, in *A. J. P.*, 1871, 263; from *Amer. Chem.*, April, 1871. The Br. Pharm. requires that when cochineal is macerated in water no insoluble powder shall be separated, and that when incinerated with free access of air it shall yield not more than 6 per cent. of ash.

Cochineal has been adulterated by causing certain heavy substances, such as powdered talc, lead carbonate, and barium sulphate, by shaking in a bag or otherwise, to adhere, by means of some glutinous material, to the surface of the insects, and thus increase their weight. Cochineal yields 1·5 per cent. of ashes. Five specimens of the drug have been examined, which left in their ashes respectively 8, 12, 16, 18, and 25 per cent. of the salt of baryta. (*A. J. P.*, 1870, p. 220.) The fraud may be detected by the absence, under the microscope, of a woolly appearance which characterizes the white powder upon the surface of the unadulterated insect. Metallic lead, which is said frequently to exist in fine particles in the artificial coating, may be discovered by powdering the cochineal and suspending it in water, when the metal will remain behind. Grains of a substance artificially prepared to imitate the dried insect have been mixed with the genuine in France. A close inspection will serve to detect the difference. (*Journ. de Pharm.*, 3e sér., ix. 110.) Vermilion and chrome-red (lead dichromate) are said also to have been largely used in the adulteration of carmine, to the extent sometimes of 60 or even 70 per cent. (*P. J. Tr.*, 1860, p. 547.) There can be no difficulty in detecting them by the appropriate tests. Starch has been used, according to Prof. Maisch, for the same purpose in the United States, and in one specimen he found 57·14 per cent. (*A. J. P.*, xxxiii. 18.) Artificial cochineal, prepared by coloring exhausted cochineal powder with rosaniline and forming it into grains, has been found in commerce. It may be recognized by the facility with which it forms a paste with water.

The importations of cochineal have diminished, owing to the gradual replacement of this dye by the newer azo colors. In 1889, 550,000 lbs. were brought into the United States; in 1895, 1896, and 1897, the importations were 134,205 lbs., 161,330 lbs., and 142,261 lbs. respectively. The reduction in price has been such that at present the production in the Canaries is said not to be remunerative.

Medical Properties, etc. Cochineal is supposed by some to possess anodyne properties, but is probably useless. In pharmacy it is employed to color tinctures and tooth-powders. To infants with *whooping-cough*, cochineal in substance is given in the dose of about one-third of a grain (0·02 Gm.) three times a day. The dose of a tincture (one part in eight parts of diluted alcohol) is for an adult from twenty to thirty drops (1·25–1·9 C.c.). In *neuralgia*, Sauter gave half a tablespoonful (7·5 C.c.) with asserted cure.

CODEINA. U. S., Br. Codeine.

$C_{18}H_{21}NO_3.H_2O$; 316·31. (CŌ-DĒ-Ī'NĂ.) $C_{18}H_{21}NO_3.H_2O$; 317.

"An alkaloid obtained from Opium." *U. S.* "An alkaloid, $C_{17}H_{18}(CH_3)NO_3,H_2O$, obtained from opium or from morphine." *Br.*

Codeia; Codeinum, *P. G.*; Codeine, *Fr.*; Codein, *G.*

*Codeine** was discovered in 1832 by Robiquet in morphine hydrochlorate prepared according to the process of Gregory. It exists in opium combined like morphine with meconic acid, and is extracted along with that alkaloid in the preparation of the hydrochlorate. (See *Morphina.*) When the solution of the mixed morphine and codeine hydrochlorates is treated with ammonia, the former alkaloid is precipitated, and the codeine, remaining in solution, may be obtained by evaporation and crystallization. It may be purified by treating the crystals with hot ether, which dissolves them and yields the codeine in colorless crystals on spontaneous evaporation. Codeine is the methyl derivative of morphine, as shown in the formula $C_{17}H_{18}(CH_3)NO_3$. It may be formed artificially from morphine by treating this latter successively with methyl iodide and fixed alkali. (Grimaux, 1881, *Jour. Chem. Soc.*, 44, 358.) Codeine occurs in "white, or nearly translucent, orthorhombic prisms, or octohedral crystals, odorless, having a faintly bitter taste, and slightly efflorescent in warm air. Soluble, at 15° C. (.99° F.), in 80 parts of water† and in 3 parts of alcohol. In boiling water Codeine melts into oily drops which dissolve in 17 parts of the water. It is very soluble in boiling alcohol; also soluble in 30 parts of ether, and in 2 parts of chloroform. At 100° C. (212° F.) Codeine loses its water of crystallization (5·67 per cent.); at 155° C. (311° F.) it melts, forming a colorless liquid; and, when ignited, it is consumed without leaving a residue. Codeine is alkaline to litmus paper. If 0·1 Gm. of Codeine be dissolved in 6 C.c. of cold, concentrated sulphuric acid (free from nitrose), the resulting liquid should be colorless. If about 2 C.c. of this solution be poured into a small porcelain capsule, and 1 drop of highly diluted nitric acid (made by adding 1 drop of nitric acid to 200 C.c. of water) added, a bluish-red tint gradually changing to pale blue will be developed. Another portion of the same solution, of about 2 C.c., gently warmed, and mixed with 1 drop of a mixture of 1 volume of ferric chloride test-solution and 19 volumes of water, likewise assumes a bluish or blue tint (difference from *morphine*). On adding to 5 C.c. of an aqueous solution of Codeine (1 in 100) 10 drops of bromine water, and shaking so as to redissolve the precipitate formed, the liquid will gradually develop a light claret-red tint. This tint may be developed at once by the addition of ammonia water. On sprinkling 0·05 Gm. of Codeine upon 2 C.c. of nitric acid (specific gravity 1·200), the crystals will turn red, but the acid, even when warmed, will acquire only a yellow color (difference from and absence of *morphine*)." *U. S.* "The alkaloid dissolves in an excess of *sulphuric acid*, forming a colorless solution, a small quantity of which, when gently warmed on a water-bath with 2 drops of *solution of ammonium molybdate*, or with a trace of *ferric chloride* or *potassium ferricyanide*, develops a blue or bluish-black color, which, on the addition of a minute trace of *diluted nitric acid*, changes to a bright scarlet, becoming orange. Heated to redness in air it yields no ash. Moistened with *nitric acid* the liquid becomes yellow but not red. A 2 per cent. solution of Codeine in *water* acidulated with a few drops of *hydrochloric acid* gives a whitish precipitate with *solution of potassium hydroxide*, but not with *solution of ammonia*. A saturated solution of Codeine in *water* acidulated with *hydrochloric acid* should give no blue

* Apocodeine, $C_{18}H_{19}NO_2$. This alkaloid, discovered in 1869 by Matthiessen and Wright, is made by heating a concentrated solution of zinc chloride with codeine. It is soluble in alcohol, ether, and chloroform; insoluble in water. It gives a reaction similar to apomorphine, but is more stable. It has been found by Dujardin-Beaumetz to be about equal to apomorphine in the same dose; and it also acts as an expectorant in a manner similar to apomorphine. It may be used hypodermically if the solution be *perfectly neutral.*

A second derivative from codeine, isomeric with it in formula, has been obtained by Merck as a by-product in the manufacture of apocodeine, and has received the name of *pseudocodeine.* It differs from codeine in its higher melting point, 182° C. (359·6° F.), and in its property of being instantly precipitated by ammonia, in the form of crystalline needles, not only from cold but likewise from boiling aqueous solutions of its salts. According to Kobert, it resembles codeine in its physiological action.

† Tambach and Henke assert that codeine is soluble in 118·35 parts of water at 15° C. (*Merck's Report*, 1897, 305.)

color, but only gradually a dull green, on the addition of *test-solution of ferric chloride* and a very dilute solution of *potassium ferricyanide* (absence of morphine and other impurities.)" *Br.* When added in excess to boiling water, the undissolved portion melts and sinks to the bottom, having the appearance of an oil. It may be separated from morphine by a solution of potassa or soda, which dissolves the morphine and leaves the codeine. It has an alkaline reaction on test-paper, and combines with acids to form salts, some of which are crystallizable, particularly the nitrate. Its capacity of saturation is almost identical with that of morphine. According to Robiquet, 1 part of hydrochloric acid is saturated by 7·837 of codeine, and by 7·88 of morphine. It is distinguishable, however, from the latter principle by the different form of its crystals, which are octohedral, by its solubility in boiling ether, greater solubility in water, and insolubility in alkaline solutions, and by not assuming a red color with nitric acid, or a blue one with ferric salts. Tincture of galls precipitates from its solutions a codeine tannate. Crystallized from a watery solution, it contains about 6 per cent. of water, which is driven off at 100° C. (212° F.). The crystals obtained from a solution in ether contain no water.

Medical Properties. It is probable that pure codeine is a very feeble alkaloid, tolerated by the human system in very large doses. On the other hand, cases of severe poisoning have been published, and experimenters have claimed for it a very powerful influence upon the lower animals. As late as 1874, Dr. Myrtle reported the instance of a man who was almost killed by four grains of codeine, prepared by Messrs. Smith, of Edinburgh. (*Brit. Med. Journ.*, 1874. i. 478.) The symptoms were first vascular excitement and exhilaration, then depression, with great anxiety, nausea and vomiting, cold, pale, moist skin, slight contraction of the pupil, and delirious sleeplessness. Spratling reports a case in which eight grains of codeine produced in a young woman great restlessness, convulsive movements, intense irritation of the whole skin, contraction of the pupils, slowing of the respiration to twelve per minute, and light sleep. On the other hand, Dr. S. Weir Mitchell took five grains of codeine without effect, save some nausea, slight giddiness, and cerebral heaviness, and a trifling acceleration of the pulse; whilst we have given codeine prepared by Powers & Weightman, of Philadelphia, in doses of eight grains a day without distinct effect. It is very evident that commercial codeine has been and probably still is of varying composition, and the results frequently obtained have been produced by coherent alkaloids. Mr. Wm. Weightman once informed us that nearly the whole product of their laboratory went to France, where it appeared to be largely used as a calmative drug, free from many of the objections to opium, but in no way comparing with it in power. It has been highly lauded in the treatment of *diabetes mellitus*, and cases of recovery under its use reported. In the grave form of this disorder we have seen it fail to exert any perceptible influence, but the evidence is sufficient to demand a fair trial of the remedy in any individual case. Medical practitioners often use it to quiet *cough*, to allay *intestinal pain*, and to fulfil various other of the minor narcotic indications for which opium is commonly administered. On account of its frequent contamination with morphine, care should be exercised as to the commencing dose, but no effect at all is to be expected, if the alkaloid be pure, from less than one grain (0·06 Gm.), and this dose may be rapidly increased until some symptoms are produced. It may be given in pill or in syrupy solution.

CODEINÆ PHOSPHAS. Br. Codeine Phosphate.

(CŌ-DĒ-Ī'NÆ FHŎS'FHĂS.)

"The phosphate, $(C_{17}H_{18}(CH_3)NO_3,H_3PO_4)_2,3H_2O$, of an alkaloid obtained from opium or from morphine." *Br.* This salt is official for the first time in the British Pharmacopœia; it has been introduced because of its easy solubility and stability; on account of its large percentage of codeine (about 70 per cent.) it is well fitted for hypodermic injections. It occurs in "White crystals which have a slightly bitter taste. It is soluble in 4 parts of *water*, much less soluble in *alcohol* (90 per cent.). A 5 per cent. aqueous solution has a slightly acid reaction, and yields a whitish precipitate with *solution of potassium hydroxide*, but not with *solution of ammonia*. It affords the reactions characteristic of Codeine and of phosphates. It loses its water of crystallization when dried at 212° F. (100° C.), and at a higher temperature melts, forming a yellowish-brown liquid. It should yield no characteristic reaction with the tests for chlorides or sulphates. It should not be colored blue by *test-solution of ferric chloride* (absence of morphine)." *Br.*

The medical properties of codeine phosphate are the same as those of codeine. Dose, from one to two grains (0·06 to 0·13 Gm.).

Gen. Ch. A *spathe*. *Corolla* six-parted, with a tube proceeding directly from the root. *Capsules* three, connected, inflated. *Willd.*

Colchicum autumnale. Willd. *Sp. Plant.* ii. 272; Woodv. *Med. Bot.* p. 759, t. 258. This species of Colchicum, often called *meadow-saffron*, is a perennial bulbous plant, the leaves of which appear in spring, and the flowers in autumn. Its manner of growth is peculiar, and deserves notice as connected in some measure with its medicinal efficacy. In the latter part of summer, a new bulb, or *cormus* as the part is now called, begins to form at the lateral inferior portion of the old one, which receives the young offshoot in its bosom and embraces it half round. The new plant sends out fibres from its base, and is furnished with a radical spathe, which is cylindrical, tubular, cloven at top on one side, and half under ground. In September, from two to six flowers, of a lilac or pale-purple color, emerge from the spathe, unaccompanied with leaves. The corolla consists of a tube five inches long, concealed for two-thirds of its length in the ground, and of a limb divided into six segments. The flowers perish by the end of October, and the rudiments of the fruit remain under ground till the following spring, when they rise upon a stem above the surface, in the form of a three-lobed, three-celled capsule. The leaves of the new plant appear at the same time: so that in fact they follow the flower instead of preceding it, as might be inferred from the order of the seasons in which they respectively show themselves. The leaves are radical, spear-shaped, erect, numerous, about five inches long, and one inch broad at the base. In the mean time, the new bulb has been increasing at the expense of the old one, which, having performed its appointed office, perishes; while the former, after attaining its full growth, sends forth shoots, and in its turn decays. The old bulb in its second spring, and a little before it perishes, sometimes puts forth one or more small bulbs, which are the sources of new plants.

C. autumnale is a native of the temperate parts of Europe and of Northern Africa, growing in moist pastures and meadows. Attempts have been made to introduce its culture into this country, but with no great success; though small quantities of the bulb, of apparently good quality, have entered commerce. The flowers possess virtues similar to those of the bulb.

Colchici Radix. The medicinal virtue of the bulb depends much upon the season at which it is collected. Early in the spring it is too young to have fully developed its peculiar properties; and late in the fall it has become exhausted by the nourishment afforded to the new plant. The proper period for its collection is from the early part of June, when it has usually attained perfection, to the middle of August, when the offset appears.* It may be owing, in part, to this inequality at different seasons that entirely opposite reports have been given of its powers. Krapf ate whole bulbs without inconvenience; Haller found the bulbs entirely void of taste and acrimony; and we are told that in Carniola the peasants use it as food with impunity in the autumn. On the other hand, there can be no doubt of its highly irritating and poisonous nature, when fully developed, under ordinary circumstances. Perhaps soil and climate may have some influence in modifying its character.

The bulb is often used in the fresh state in the countries where it grows, as it is apt to be injured in drying, unless the process is carefully conducted. The usual plan is to cut the bulb,

* Dr. Christison, however, has found the roots collected in April to be more bitter than those gathered in July, and conjectures that the common opinion of their superior efficacy at the latter season may not be well founded. Prof. Schroff states, as the result of his observation, that the autumnal root is much stronger than that dug in the summer. (See *A. J. P.*, xxix. 324.)

as soon as possible after it has been dug up, into thin transverse slices, which are spread out separately upon paper or perforated trays and dried with a moderate heat. The reason for drying it quickly after removal from the ground is that it otherwise begins to vegetate, and a change in its chemical nature takes place; and such is its retentiveness of life that, if not cut in slices, it is liable to undergo a partial vegetation even during the drying process. Dr. Houlton recommends that the bulb be stripped of its dry coating, carefully deprived of the bud or young bulb, and then dried whole. It is owing to the high vitality of the bud that the bulb is so apt to vegetate. During desiccation there is great loss of weight, 70 per cent. being the average for a number of years in the laboratory of Messrs. Allen & Hanburys, in London.

Properties. The recent bulb or cormus of *C. autumnale* resembles that of the tulip in shape and size, and is covered with a brown membranous coat. Internally it is solid, white and fleshy, and, when cut transversely, yields, if mature, an acrid milky juice. There is often a small lateral projection from its base, which is the bud for the development of a new plant: this bud is frequently broken off in drying. When dried, and deprived of its external membranous covering, the corm is of an ash-brown color, convex on one side, and somewhat flattened on the other, where it is marked by a deep groove extending from the base to the summit. As found in commerce, it is always in the dried state, sometimes in segments made by vertical sections of the bulb, but generally in transverse circular slices, about the eighth or tenth of an inch in thickness, with a notch at one part of their circumference. "About 25 Mm. long, ovoid, flattish and with a groove on one side; externally brownish and wrinkled; internally white and solid; often in transverse slices, reniform in shape, and breaking with a short, mealy fracture; inodorous; taste sweetish, bitter, and somewhat acrid." *U. S.* The cut surface is white and of an amylaceous aspect. Examined with the microscope, the corm is seen to be composed of large irregular cells, full of ovoid, angular, sometimes compound, starch grains, and interspersed with spiral vessels in vascular bundles. The odor of the recent bulb is said to be hircine. It is diminished, but not lost, by drying. The taste is bitter, hot, and acrid. Wine and vinegar extract all the virtues of the bulb.

The alkaloid *colchicine*, whose nature was first precisely made out by Geiger and Hesse, has been the subject of much controversy, for an account of which the reader is referred to the seventeenth edition of the U. S. Dispensatory, page 427, foot-note. It is now recognized to be the *methyl ester* of *acetyl-trimethyl colchicinic acid*, and has the formula $C_{22}H_{25}NO_6$. When colchicine is heated with 3 parts of hydrochloric acid for two hours on the water-bath, it is decomposed, with the formation of *colchicinic acid*, $C_{16}H_{15}NO_5$, and *dimethyl colchicinic acid*, $C_{18}H_{19}NO_5$. When colchicine is boiled with water containing sulphuric acid, it is decomposed according to the formula $C_{22}H_{25}NO_6 + H_2O = C_{21}H_{23}NO_6 + CH_3OH$, the products being *colchiceine* and methyl alcohol. The colchiceine is formed so readily that some of the reactions commonly attributed to colchicine itself are probably due to its decomposition product. Colchiceine, which is *aceto-trimethyl colchicinic acid*, can also be made synthetically by heating *trimethyl colchicinic acid* with acetic anhydrides to 100° C. Colchicine has also been built up synthetically from colchiceine, sodium methylate, and methyl iodide, which are heated together to 100° C. (Johanny, Zeisel, *Monatshefte*, 9, 868.) Colchicine is soluble in water and alcohol, also in chloroform, benzol, and amyl alcohol. Dragendorff describes it as soluble in ether, but Zeisel as scarcely so. Insoluble in petroleum ether. It is colored yellow with concentrated sulphuric acid, and blue, turning to brown and yellow, with nitric acid. It forms precipitates with the usual alkaloidal reagents.

Dr. A. T. Thompson states that the milky juice of fresh colchicum produces a fine blue color if rubbed with the tincture of guaiac, and that the same effect is obtained from an acetic solution of the dried bulb. He considered the appearance of this color, when the slices were rubbed with a little distilled vinegar and tincture of guaiac, a proof that the drug was good and had been well dried. Dr. J. M. Maclagan has shown that this change of color is produced with the albumen, which is not affected if previously coagulated: so that the value of the test consists simply in proving that the drying has not been effected at a heat above 180° F., or the temperature at which albumen coagulates. A very deep or large notch in the circumference of the slices is an unfavorable sign, as it indicates that the bulb has been somewhat exhausted in the nourishment of the offset. The decoction yields a deep blue precipitate with solution of iodine, white precipitates with lead acetate and subacetate, mercurous nitrate, and silver nitrate, and a slight precipitate with tincture of galls. The value of colchicum is best tested by its bitterness. For method of assaying colchicum, by K. Schwickerath, see *Pharm. Rund.*, 1893, 282.

Medical Properties and Uses. When taken internally in therapeutic dose, colchicum usually produces no other symptoms than intestinal pains and looseness of the bowels. In some rare cases it is said to give rise to copious diuresis or diaphoresis instead of purging. When larger amounts are exhibited, the purging is more pronounced, and there may be also vomiting. With these symptoms there may be some depression, which seems to be due to the gastro-intestinal irritation rather than to the direct action of the poison. In an overdose, it may produce dangerous and even fatal effects. Excessive nausea and vomiting, abdominal pains, purging and tenesmus, great thirst, sinking of the pulse, coldness of the extremities, and general prostration, with occasional symptoms of nervous derangement, such as headache, delirium, and stupor, are among the results of its poisonous action. A peculiarity of its influence is that when its dose is increased beyond a certain point there is not a corresponding increase in the rapidity of the fatal issue. This is probably because it kills not by a direct influence upon the heart or the nervous system, but by causing gastro-enteritis. On post-mortem examination the alimentary mucous membrane is found much inflamed.

Colchicum was well known to the ancients as a poison, and is said to have been employed by them as a remedy in gout and other diseases. Störck revived its use among the moderns. He gave it as a diuretic and expectorant in *dropsy* and humoral *asthma*, and on the continent of Europe it acquired considerable reputation in these complaints; but the uncertainty of its operation led to its general abandonment, and it had fallen into almost entire neglect, when Dr. Want, of London, again brought it into notice by attempting to prove its identity with the active ingredient of the *eau médicinale d'Husson*, so highly celebrated as a cure for gout. In James's Dispensatory, printed in 1747, it is said to be used in gout as an external application. The chief employment of the meadow-saffron is at present in the treatment of *gout* and *rheumatism*, in which experience has abundantly proved it to be a highly valuable remedy. We have, within our own observation, found it especially useful in these affections, when of a shifting or neuralgic character. It sometimes produces relief without obviously affecting the system; but it is more efficient when it evinces its influence upon the skin or alimentary canal. Professor Chelius states that it changes the chemical constitution of the urine in arthritic patients, producing an evident increase of the uric acid. Dr. Maclagan has found it greatly to increase the proportion of both urea and uric acid in the urine, and, where these previously existed in the blood, to separate them from it. (*Ed. Monthly Journ. of Med. Sci.*, N. S., v. 23.) But Graves and Gardner affirm that the urates diminish under its influence, and in a very careful and extended research Dr. A. B. Garrod found that its action upon the uric acid elimination is very irregular and uncertain. It has been found useful in *prurigo*, *urticaria*, and other cutaneous affections of a gouty nature. In modern practice it is employed almost solely in gout. It is generally given in the state of vinous tincture (see *Vinum Colchici Radicis*); but there are various other official preparations, any one of which may be used efficiently. The dose of the dried bulb is from two to eight grains (0·13–0·52 Gm.), which may be repeated every four or six hours till its effects are obtained.*

The alkaloid *colchicine* acts like colchicum; according to Maret and Combemale, in doses of one-twelfth of a grain (0·005 Gm.) producing violent diarrhœa, with diminished urinary secretion; in doses of one-thirty-second of a grain (0·002 Gm.) causing some abdominal disturbance, with increased diuresis. According to Dr. J. Sprega, three grains (0·2 Gm.), repeated in three hours, caused violent gastro-enteritis, ending in death in thirty-one hours. (*Gazz. d. Ospitali*, Oct. 1890.) *Colchicine salicylate* (*Colchisal*) is a yellow amorphous powder, soluble in water, alcohol, and ether, the dose being one-hundredth of a grain (0.0006 Gm.) every four hours.

Colchici Semen.—The seeds of the meadow-saffron ripen in summer, and should be collected about the end of July or beginning of August. They never arrive at maturity in plants cultivated in a dry soil or in confined gardens. (Williams.) They are nearly spherical, about the eighth of an inch in diameter, of a reddish-brown color externally, white within, and of a bitter acrid taste. "Subglobular, about 2 Mm. thick, very slightly pointed at the hilum; red-

* In preparing colchicum pharmaceutically, if it be desired to retain the colchicine unchanged, both acids and alkalies should be avoided, especially when heat is employed. Of the official preparations, the two fluid extracts contain the colchicine as in nature; the acetic extract has a portion at least of colchiceine in its composition. In the wines, when kept, the colchicine probably passes gradually into colchiceine. (*A. J. P.*, 1867, p. 97.) But it has not been proved that these latter preparations are in any degree less efficacious remedially; and, in the absence of all experience to the contrary, the inference is that colchiceine may have all the powers of colchicine; for the acetic extract, and the wines after being long kept, have often been used in practice, without having been found less effectual than other preparations of colchicum.

dish brown, finely pitted, internally whitish; very hard and tough; inodorous; taste bitter and somewhat acrid." *U. S.* They are chiefly composed of a gray horny albumen, constituted of very thick-walled cells, and surrounded by a closely adherent testa. The leafless embryo is very small, and is situated close to the surface opposite the strophiole. Dr. Williams, of Ipswich, England, first brought them into notice in 1820 as superior to the bulb. Prof. Schroff, however, has found that their activity is inferior to that of the dried bulb, dug in autumn (*A. J. P.*, xxix. 324); and recent studies indicate that they contain only a very small percentage of alkaloid. A wine, fluid extract, and tincture of the seeds are directed in the U. S. Pharmacopœia. Their dose is about the same as that of the bulb.

COLLODIUM. U. S., Br. Collodion.

(CŌL-LŌ'DI-ŬM.)

Collodion, *Fr.*; **Collodium**, *G.*

"Pyroxylin, *thirty grammes* [or 463 grains]; Ether, *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims]; Alcohol, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]. To the Pyroxylin, contained in a suitable bottle, add the ether, and let it stand for fifteen minutes; then add the Alcohol, and shake the bottle until the Pyroxylin is dissolved. Cork the bottle well, and set it aside until the liquid has become clear. Then decant the clear portion from any sediment which may have formed, and transfer it to bottles, which should be well corked. Keep the Collodion in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

"Pyroxylin, 1 *ounce* (Imperial) or 10 grammes; Ether, 36 *fl. ounces* (Imp. meas.) or 360 cubic centimetres; Alcohol (90 per cent.), 12 *fl. ounces* (Imp. meas.) or 120 cubic centimetres. Mix the Ether and the Alcohol; add the Pyroxylin; set aside for a few days; should there be any sediment, decant the clear Collodion." *Br.*

Collodion is a solution of gun cotton. On account of the facility with which ether evaporates, it is the better menstruum for remedial purposes; but gun cotton will not dissolve in that liquid when quite pure, and the addition of strong alcohol is necessary. Formerly the U. S. Pharmacopœia directed that the gun cotton be prepared at the time of making the collodion, giving directions for the purpose, but at the revision of 1870 the process of the British Pharmacopœia was substantially adopted, a formula for the preparation of pyroxylin being given separately in the Pharmacopœia. The present formula differs very slightly from that of 1870, containing a little more pyroxylin and alcohol. (See *Pyroxylin.*) A change has been made, however, in directing the collodion to be decanted from the sediment. In the Pharm. 1870 the sediment was directed to be re-incorporated with the clear collodion, and the result was the making of a tougher film. This sediment consists of undecomposed filaments of cotton, and these become partially felted as the ethereal liquid evaporates and the film is forming; this direction of the former Pharmacopœia was usually disregarded, although for many purposes the cloudy film is to be preferred.

Collodion is a transparent, colorless liquid, of a syrupy consistence and an ethereal smell. When applied to a dry surface, the ether quickly evaporates, and a transparent film is left, having remarkable adhesiveness and contractility. On account of the great volatility of ether, collodion must be kept in bottles well stopped. When insecurely kept, the liquid thickens and becomes less fit for the use of the surgeon. The thickened liquid sometimes contains acicular crystals. The addition of ether will generally restore the collodion to its original condition.

Collodion was first applied to the purposes of surgery by Dr. J. Parker Maynard,* of Boston, when a student of medicine, in January, 1847. It is employed for holding together the edges of incised wounds, for covering ulcers or abraded or diseased surfaces, chilblains, chapped nipples, etc., with an impervious film not acted upon by water, and for encasing parts which require to be kept without relative motion. It is applied brushed over the part, or by means of strips of muslin. In whatever way applied, the solvent quickly evaporates, and leaves the solid adhesive material, which is soluble neither in water nor in alcohol. The rigid film thus formed contracts with a good deal of force. This property adapts collodion for certain purposes, such as drawing together the edges of wounds, exciting pressure on buboes, etc. When,

* Dr. Maynard recommended the following formula. Take of sulphuric acid of sp. gr. 1·850 *two parts*, and of nitric acid of sp. gr. 1·450 *one part*. Mix them, and, having permitted the heat to fall to about 100° F., add raw cotton to saturation. Let it macerate for one or two hours; then pour off the acids, wash the cotton till the washings cease to affect litmus paper, and dry thoroughly. The gummy matter thus formed is now to be dissolved in ether of the sp. gr. about ·750, or in a mixture of three parts of pure ether and one part of alcohol of 95 per cent. Two ounces of cotton will make about a pint of collodion. (*Boston Med. and Surg. Journ.*, 1866, p. 39.)

however, the surgeon desires simply to protect a surface, a flexible, non-contracting film is preferable, and the official flexible collodion should be used. Collodion has been variously medicated, and thus made the vehicle of several important medicines for external application. *Iodized collodion* has been proposed by Dr. C. Fleming, for the purpose of obtaining the specific effects of iodine in a rapid manner, especially on tumors. It is made by dissolving from ten to twenty grains of iodine in a fluidounce of collodion. See *Collodium Iodatum* (N. F.). M. Aran has proposed a *ferruginous collodion*, made of equal parts of collodion and tincture of ferric chloride, as a remedy in erysipelas.* A *caustic collodion* may be prepared by dissolving 4 parts of corrosive sublimate in 30 of collodion. Dr. Macke, of Sorau, has used this preparation for destroying nævi materni. The eschar formed is one or two lines in thickness, and separates in from three to six days, leaving but a trifling cicatrix. (See *A. J. P.*, May, 1858, for formulas in which collodion is made the vehicle of iodine, belladonna, sulphur, etc.) All these medicated collodions are best applied by means of a camel's-hair brush. See also *Collodium Tiglii* (N. F.), and *Collodium Salicylatum Compositum* (N. F.).†

COLLODIUM CANTHARIDATUM. U. S. (Br.) Cantharidal Collodion.

[Blistering Collodion.]

(CŌL-LŌ'DĮ-ŬM CAN-THĂR-Į-DĀ'TŬM.)

Collodium Vesicans, *Br.;* Blistering Collodion; Collodium Cantharidatum, *P. G.;* Collodium Cantharidale, s. Vesicans; Collodion vésicant (cantharidé), *Fr.;* Blasenziehendes Collodium, *G.*

"Cantharides, in No. 60 powder, *sixty grammes* [or 2 ounces av., 51 grains]; Flexible Collodion, *eighty-five grammes* [or 3 ounces av.]; Chloroform, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Pack the Cantharides firmly in a cylindrical percolator, and gradually pour Chloroform upon it, until the powder is exhausted. Recover the chloroform by distillation from a water-bath, and evaporate the residue, in a capsule, on a water-bath, until it weighs *fifteen grammes* [or 231 grains]. Dissolve this in the Flexible Collodion, and set it aside to become clear by settling. Finally pour off the clear portion from any sediment which may have formed, and transfer it to bottles, which should be securely corked. Keep the Cantharidal Collodion in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

"Blistering Liquid, 20 *fl. ounces* (Imperial measure) or 200 cubic centimetres; Pyroxylin, ½ *ounce* (Imp.) or 5 grammes. Add the Pyroxylin to the Blistering Liquid in a stoppered bottle; shake them together until the Pyroxylin is dissolved." *Br.*

The official process differs considerably in the manipulation from that of the U. S. P. 1870, although the finished preparation is not essentially different. Chloroform is used to extract the cantharidin from the powdered cantharides, by percolation; the chloroform is afterwards recovered by distillation, and the oily residue containing the vesicant is dissolved in the collodion. The efficiency of chloroform as a solvent of cantharidin has been shown by Professor Procter. The original process of M. Ilisch was to exhaust, by percolation, a pound of cantharides, with a mixture consisting of a pound of ether and three ounces of acetic ether, and in two ounces of this liquid to dissolve 25 grains of gun cotton. Professor Procter states that it has been found more advantageous to exhaust the flies with ether, distil off the ether, and mix the oily residue with collodion already prepared of the proper consistence (*A. J. P.*, xxiv. 303); and this is probably a better formula than the official, if care is used in recovering the ether to avoid contact with flame. Mr. Charles S. Rand (*A. J. P.*, xxii. 18) states that Ilisch's preparation, made with double the proportion of ether, vesicates equally well, and proposes the addition of about 1 per cent. of Venice turpentine, which he has found to prevent the dis-

* *Paresi's Styptic Collodion.* Collodion, 100 parts; carbolic acid, 10 parts; pure tannin, 5 parts; benzoic acid, 3 parts. Agitate till thoroughly mixed. On evaporation it leaves a brown pellicle, adhering strongly to tissues, and effecting instant coagulation of the blood and albumen.

Collodium Belladonnæ, Belladonna Collodion. Mix 10 fluidounces each of fluid extract of belladonna leaves and ether, and set aside for 12 hours. Decant and dissolve therein 130 grains camphor, 183 grains pyroxylin, 365 grains Canada balsam, 183 grains castor oil. (Naylor.)

Iodoform Collodion is made, according to Moleschott, by dissolving 1 part of iodoform, in fine powder, in 15 parts of flexible collodion. It is recommended for relieving pain caused by gout, and for orchitis, pericarditis, etc. See also *Collodium Iodoformatum* (N. F.).

† *Silk Collodion.* M. Persoz the younger prepares a collodion by bringing silk to the condition of the material from which the worm spins its thread. This he does by dissolving it in a solution of zinc chloride, and then separating the solvent by means of dialysis. The chloride passes through the parchment of a dialyser, leaving the silk substance in a soft fibreless state. The material thus obtained is said to be applicable to photographic purposes. Before it could be used as collodion, it would be necessary to dissolve it in a volatile liquid which would evaporate spontaneously on application to the surface. (See *A. J. P.*, 1867, p. 182.)

agreeable and sometimes painful contraction of the collodion upon drying. The preparation may be kept indefinitely, in an opaque glass-stoppered bottle, without change; but on exposure to the light, the greenish coloring matter of the flies bleaches, and the liquid becomes yellowish.* *Cantharidized collodion* may be made from cantharidin by dissolving four grains of cantharidin in one thousand grains of flexible collodion.

Cantharidal collodion is a very convenient epispastic remedy. It may be applied to the surface by means of a camel's-hair brush, and after the evaporation of the ether, which takes place in less than a minute, may be reapplied if the surface should not be well covered. It produces a blister in about the same time as the ordinary cerate, and has the advantages that it is applied with greater facility, is better adapted to cover uneven surfaces, and retains its place more certainly. According to Mr. Rand, if the evaporation of the ether be restrained by a piece of oiled silk immediately after its application, it will act much more speedily.

COLLODIUM FLEXILE. U. S., Br. Flexible Collodion.

(CŌL-LŌ'DI-ŬM FLĔX'I-LĒ.)

Collodium Elasticum, *P. G.;* Collodion élastique, *Fr.;* Elastisches Collodium, *G.*

"Collodion, *nine hundred and twenty grammes* [or 32 ounces av., 198 grains]; Canada Turpentine, *fifty grammes* [or 1 ounce av., 334 grains]; Castor Oil, *thirty grammes* [or 1 ounce av., 25 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Weigh the ingredients, successively, into a tared bottle, and mix them thoroughly. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

"Collodion, 12 *fl. ounces* (Imperial measure) or 480 cubic centimetres; Canada Turpentine, ½ *ounce* (Imp.) or 20 grammes; Castor oil, ¼ *ounce* (Imp.) or 10 grammes. Mix." *Br.*

The contractility of the collodion film has long been felt as a drawback to its use simply for the purposes of protection. Mr. C. S. Rand, of Philadelphia, proposed to obviate this by dissolving one part of gun cotton and three of Venice turpentine in twenty parts of ether. To give more flexibility to the film, M. Sourisseau, of Kaiserberg, suggested the addition of one part of elemi to twelve of collodion. According to Mr. Startin, of London, opacity and elasticity may be imparted at the same time by adding from half a drachm to a drachm of lard, or some similar fatty matter, previously dissolved in ether, to an ounce of collodion. The qualities of softness and elasticity may also be given by combining collodion with castor oil, in the proportion of thirty parts to two, agreeably to the plan of M. Guersant, who found it useful, thus modified, in erysipelas; and the proportion of castor oil may be increased if thought desirable. This is the method preferred by the French Codex. An elastic collodion, somewhat similar, in which, besides castor oil, Venice turpentine and white wax are ingredients, has been proposed by E. Lauras. (*P. J. Tr.*, xii. 303.) According to MM. Cap and Garot, the most successful way for obtaining an elastic collodion is to mix two parts of glycerin with one hundred of collodion. *Glycerized collodion* is exceedingly supple, does not crack and scale off from the skin, and accommodates itself to the motions of the part. In order to imitate the color of the skin, an ethereal tincture of turmeric or saffron may be added, so as to produce the desired tint. Dr. Meller has proposed a solution of shellac in highly rectified alcohol, so as to have a gelatinous consistence, as a substitute for collodion. Of all these plans, probably that followed in the official directions is the best. Dr. Tournie recommends, in superficial cervical adenitis with redness, painting the part with several layers of flexible collodion every two days. (*Med. Times and Gaz.*, 1874, p. 540.)

COLLODIUM STYPTICUM. U. S. Styptic Collodion.

(CŌL-LŌ'DI-ŬM STĬP'TI-CŬM.)

Styptic Colloid, Xylostyptic Ether; Collodion styptique, *Fr.*

"Tannic Acid, *twenty grammes* [or 308·6 grains]; Alcohol, *five cubic centimeters* [or 81 minims]; Ether, *twenty-five cubic centimeters* [or 406 minims]; Collodion, *a sufficient quantity*, To make *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Introduce the Tannic Acid, Alcohol, and Ether into a graduated bottle, agitate until the Tannic Acid is thoroughly incorporated and partially dissolved, then add enough Collodion to make up the volume to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], and shake occasionally, until the Acid is completely dissolved. Keep the product in cork-stoppered bottles, in a cool place, remote from lights or fire." *U. S.*

* *Croton Oil Collodion* is made by mixing equal weights of croton oil and flexible collodion. (*Report on Revision of U. S. Pharm., A. P. A.*, 1880.)

This collodion is a modification of the *styptic colloid* of Dr. B. W. Richardson, of London (*P. J. Tr.*, 1867, p. 29), a preparation which has had considerable use, particularly in hospitals. Experience has shown, however, that Dr. Richardson's formula contained too little tannin; the quantity has been increased in the U. S. process to 20 per cent., but this is more than will usually dissolve. The manipulation in the official formula might be improved by directing the tannic acid to be rubbed into a smooth paste in a mortar with sufficient alcohol, before introducing into the bottle. This would enable the pharmacist to prepare it extemporaneously. When applied on wounded or abraded surfaces, it soon loses the ether and alcohol, and a firm coating is left, in which, besides the tannin and colloidal substance, are the coagulated blood and secretions from the surface, forming a covering for the part by which the air is excluded. The liquid is applied with a camel's-hair brush, or by means of cotton saturated with it, to the edges of wounds closed by stitches, to ulcerated surfaces and bleeding parts. If it be desired to make a special impression on the diseased surface, carbolic acid, creosote, iodine, morphine, etc., may be incorporated with the styptic fluid.*

COLOCYNTHIS. U. S. (Br.) Colocynth.

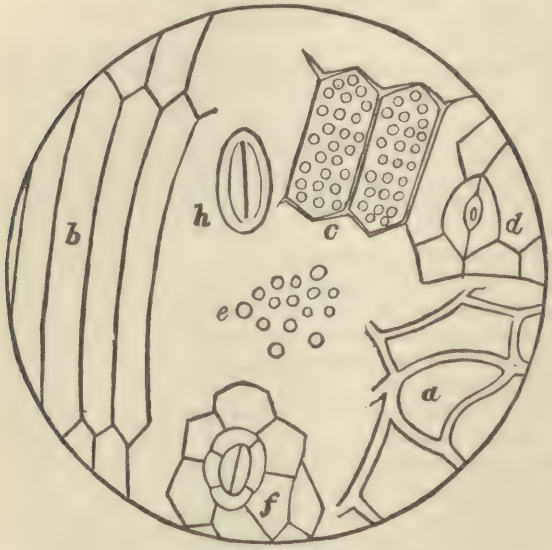
(CŎL-Ō-CŸN'THIS.)

"The fruit of Citrullus Colocynthis, Schrader (nat. ord. Cucurbitaceæ), deprived of its rind." *U. S.* "The dried pulp of the fruit of Citrullus Colocynthis, Schrad., freed from seeds." *Br.*

Colocynthidis Pulpa, *Br.*, Colocynth Pulp; Fructus Colocynthidis, *P. G.;* Poma Colocynthidis; Pulpe de Coloquinte, Coloquinte, *Fr.;* Coloquintenapfel, Koloquintenmark, Koloquinten, *G.;* Coloquintida, *It., Sp.*

Gen. Ch. MALE. *Calyx* five-toothed. *Corolla* five-parted. *Filaments* three. FEMALE. *Calyx* five-toothed. *Corolla* five-parted. *Pistil* three-cleft. *Seeds* of the *gourd* with a sharp edge. *Willd.*

Citrullus colocynthis (L.). Schrad., Engel, and Prantl.—*Cucumis colocynthis.* Willd. *Sp. Plant.* iv. 611; Woodv. *Med. Bot.* 189, t. 71. The *bitter cucumber* is an annual plant, bearing considerable resemblance to the common watermelon. The stems, which are herbaceous and beset with rough hairs, trail upon the ground, or rise upon neighboring bodies, to which they attach themselves by their numerous tendrils. The leaves, which stand alternately on long petioles, are triangular, many-cleft, variously sinuated, obtuse, hairy, of a fine green color on the upper surface, rough and pale on the under. The flowers are yellow, and appear singly at the axils of the leaves. The fruit is a globular pepo, of the size of a small orange, yellow and smooth when ripe, and contains, within a hard, coriaceous rind, a white, spongy pulp, enclosing numerous ovate, compressed, white or brownish seeds.



The plant is a native of Turkey, and abounds in the islands of the Archipelago. It grows also in various parts of Africa and Asia. Burckhardt, in his travels across Nubia, found the country covered with it; Thunberg met with it at the Cape of Good Hope; and Ainslie says that it grows in many parts of Lower India, particularly in sandy places near the sea. It is said to be cultivated in Spain, to abound in Morocco and in the neighboring countries, and even to have been collected in Japan. Colocynth from the maritime plain between the mountains of Palestine and the Mediterranean is chiefly shipped from Jaffa, and is known as *Turkish colocynth.* It is said to be of superior quality. The fruit is gathered in autumn, when it begins to become yellow, and, having been peeled, is dried quickly in a stove or in the sunshine. Thus prepared, it is imported from the Levant. Small quantities are said to be imported into England from Mogador in the form of brown, unpeeled globular gourds.† The so-called *Persian colocynth* of the London markets is very small, and has apparently been compressed in a fresh state, so that the position of the seeds is perceptible through the dry pulp. The microscopic structure and the proportion of the pulp to the seed appear to be the same as in other colocynths. (*P. J. Tr.*, xvi. 107.) Colocynth has been grown in New Mexico, but, according to Prof. Sayre, the American colocynth possesses only about two-thirds the cathartic action of the Trieste variety.

Properties. As found in commerce, colocynth is in the shape of whitish balls about the

* *Carbolized Styptic Colloid.* In this preparation advantage is taken of the antiseptic and styptic properties of carbolic acid, and a very effective hæmostatic results. It is made by adding ten per cent. of carbolic acid to official styptic collodion.

† In Union Village, Lebanon, Ohio, the Shakers formerly prepared an extract from a hybrid between the colocynth and the watermelon. The two plants were placed close to each other, and the hybrid resulting yielded the second year a gourd resembling a watermelon, but very bitter, and affording an abundant extract. This is stated to be equal in purgative properties to that of colocynth, but at present it is not manufactured.

size of an orange, very light and spongy, and abounding in seeds which constitute three-fourths of their weight. The seeds are somewhat bitter, but possess little activity, and, according to Captain Lyon, are even used as food in the north of Africa.* When the medicine is prepared for use, they are separated and rejected, the pulpy or medullary matter only being employed. This has a very feeble odor, but a nauseous and intensely bitter taste. The U. S. Pharmacopœia thus describes colocynth: "From 5 to 10 Cm. in diameter; globular; white or yellowish white; light, spongy; readily breaking into three wedge-shaped pieces, each containing, near the rounded surface, many flat, ovate, brown seeds; inodorous; taste intensely bitter. The pulp only should be used, the seeds being separated and rejected." "It should not yield the characteristic reactions with the tests for starch, and only traces of fixed oil should be removed from it by *ether*. It yields, when dried at 212° F. (100° C.) and incinerated, at least 9 per cent. of ash (indicating absence of seeds)." *Br.* Barclay considers the estimation of ash in powdered colocynth useful in proving its freedom from seeds. The pulp yields from 8·6 to 14 per cent. of ash, the seeds from 2 to 4 per cent., the whole apple 4·6 per cent. (*Amer. Drug.*, 1896, 152.) Water and alcohol extract the virtues of colocynth. It is a matter of importance to be able to determine whether the drug miller who usually powders colocynth is careful to reject the seeds. If the seeds have been ground with the dried pulp, the microscope will show the presence of numerous albuminous granules derived from the cotyledons. (W. T. Clark, *P. J. Tr.*, vii. 509.) These are best found by putting a small amount of the powder on the glass slide, adding a drop of water, and gently rubbing the cover glass over it; fragments of the double-walled embryo sac show on the outer side elongated, more or less hexagonal, thin-walled cells, and on the inner side irregular, tabular, thick-walled cells. Powdered colocynth containing a large number of starch granules has suffered adulteration. Vauquelin obtained the bitter principle of colocynth in a separate state, and called it *colocynthin*. According to Meissner, 100 parts of the dry pulp of colocynth contain 14·4 parts of colocynthin, 10·0 of extractive, 4·2 of fixed oil, 13·2 of a resinous substance insoluble in ether, 9·5 of gum, 3·0 of pectic acid (pectin), 17·6 of gummy extract derived from the lignin by means of potassa, 2·7 of calcium phosphate, 3·0 of magnesium phosphate, and 19·0 of lignin, besides water.† Colocynthin is obtained by boiling the pulp in water, evaporating the decoction, treating the extract thus procured with alcohol, evaporating the alcoholic solution, and submitting the residue, which consists of the bitter principle and potassium acetate, to the action of a little cold water, which dissolves the latter and leaves the greater part of the former untouched. Mr. Bastick obtained it by exhausting the pulp with cold water, heating the solution to ebullition, adding lead subacetate so long as a precipitate was produced, filtering the liquor when cold, adding dilute sulphuric acid gradually until it no longer occasioned a precipitate, boiling to expel free acetic acid, filtering to separate lead sulphate, evaporating cautiously nearly to

470 diameters.

a, inner layer of embryo sac; *b*, outer layer of ditto; *c*, cells of palisaded layer with granules; *d*, stomata from cotyledon; *e*, granules from cotyledons; *f*, epidermis of rind; *h*, starch granule (side view).

* Dr. Nachtigal confirms this statement of Captain Lyon's, but with the qualification that, before being eaten, the seeds are deprived of their coating by some mechanical means, and the kernels are heated to the boiling point, then washed with cold water, dried, and powdered. Professor Flückiger found a bitter principle in the testa, which accounts for its rejection as food, though rendering improper the rejection of the seed in preparing the extract. He found in the kernels about 45 per cent. of fixed oil and 18 per cent. of albumen. (*A. J. P.*, 1872, 538.)

† Dr. Walz supposed that he had found another peculiar principle, *colocynthitin*. It was obtained by treating with ether the alcoholic extract previously exhausted by water, decolorizing the ethereal solution with animal charcoal, evaporating to dryness, and dissolving the residue in anhydrous alcohol, which deposited it in crystals on spontaneous evaporation. It is white and tasteless, and is probably a resin. (*N. Jahrbuch der Pharm.*, xvi. 10.)

dryness, extracting the colocynthin from the residuum by strong alcohol, which left the salts, and finally evaporating the alcoholic solution. The following process, employed by Dr. Walz, yields it in a purer state. Colocynth is exhausted by alcohol of sp. gr. 0·84, the tincture evaporated to dryness, the residue treated with water, and the solution precipitated first with lead acetate and afterwards with lead subacetate. The yellow filtered liquor is then treated with hydrogen sulphide to separate the lead, and, after filtration, with solution of tannic acid, which throws down a compound of tannic acid and colocynthin. This is dissolved in alcohol, the tannin thrown down by lead subacetate, the excess of lead separated, and the liquid digested with animal charcoal, filtered, and evaporated. The residue, washed with anhydrous ether, is pure colocynthin. This is yellowish, somewhat translucent, brittle and friable, fusible by a heat below 100° C. (212° F.), inflammable, more soluble in alcohol than in water, but capable of rendering the latter intensely bitter. M. Mouchon states that it is insoluble in ether. It is neither acid nor alkaline; but its aqueous solution gives with infusion of galls a copious white precipitate. Its formula, according to Dr. Walz, is $C_{56}H_{84}O_{23}$. Upon the same authority it is a glucoside, being resolved by the action of sulphuric acid into sugar and a peculiar resinous substance termed *colocynthein*. Henke doubts the probability of colocynthin being a glucoside, and states that it is uncrystallizable; he reviews the methods of previous investigators, and obtained by his own process but 0·66 per cent. of colocynthin. (*Archiv d. Pharm.*, 1883, p. 200; *A. J. P.*, 1883, p. 301.) According to Johannson, colocynthin, when heated with diluted sulphuric acid, yields colocynthein, elaterin, and bryonin. (*A. J. P.*, 1885, p. 451.)* An infusion of colocynth, made with boiling water, gelatinizes upon cooling. Neumann obtained from 768 parts of the pulp, treated first with alcohol and then with water, 168 parts of alcoholic and 216 of aqueous extract. (See also paper by George Wagner, *Proc. A. P. A.*, 1893, 179.)

Medical Properties and Uses. The pulp of colocynth is a powerful drastic, hydragogue cathartic, producing, when given in large doses, violent griping, and sometimes bloody discharges, with dangerous inflammation of the bowels. Death has resulted from a teaspoonful and a half of the powder. (*Christison.*) Even in moderate doses it sometimes acts with much harshness, and it is therefore seldom prescribed alone. By some writers it is said to be diuretic. It was frequently employed by the ancient Greeks and the Arabians, though its drastic nature was not unknown to them. Among the moderns it is occasionally used in obstinate dropsy, and in various affections depending on disordered action of the brain. In combination with other cathartics it loses much of its violence, but retains its purgative energy, and in this state is extensively employed. The compound extract of colocynth is a favorite preparation with many practitioners; and, combined with calomel, extract of jalap, and gamboge, it forms a highly efficient and safe cathartic, especially useful in congestion of the portal circle and torpidity of the liver. (See *Pilulæ Catharticæ Compositæ.*) The dose of colocynth is from five to ten grains (0·33–0·65 Gm.). It is best administered in minute division, effected by trituration with gum or farinaceous matter. The active principle has sometimes been employed, and, in the impure state in which it is prepared by the process of M. Emile Mouchon, may be given in the dose of a grain (·065 Gm.).†

Thunberg states that the fruit of *C. colocynthis*, at the Cape of Good Hope, is rendered so mild by being properly pickled that it is eaten both by the natives and by the colonists; but, as it is thus employed before attaining perfect maturity, it is possible that the drastic principle may not have been developed.

CONFECTIONES. Confections.

(CŌN-FĔC-TI-Ō'NĒS—kŏn-fĕk-shē-ō'nēz.)

Electuaries; Conserves, Electuaires, Saccharolés mous, *Fr.*; Conserven, Latwergen, *G.*

Under the general title of Confections, the Pharmacopœias include all those preparations having the form of a soft solid, in which one or more medicinal substances are incorporated with saccharine matter, with a view either to their preservation or more convenient administration. But two confections have been retained in the present revision of the U. S. Pharmaco-

* According to Ernst Johannson (*Inaug. Diss.*, Dorpat, 1884), colocynthin can readily be found in the alvine discharges and in the body, after poisoning by it, by the following tests: $\frac{1}{20}$ milligramme will give with concentrated sulphuric acid a reddish-yellow color, deepening into red; Froehde's reagent strikes with $\frac{1}{40}$ milligramme a cherry-red color; one part of ammonium vanadanate in 200 parts of concentrated sulphuric acid makes with $\frac{1}{40}$ milligramme a blood-red spot surrounded by a bluish tint; alcohol with sulphuric acid strikes a yellow color, not altered by warming; selenosulphuric acid (H_2SeSO_3) does the same; basic lead acetate and tannic acid precipitate by weak solutions.

† For further processes for preparing colocynthin, see U. S. D., fourteenth edition, or *A. J. P.*, xxviii. 166, 1863, 116.

pœia. The old division into Conserves and Electuaries has been abandoned; but, as there is some ground for the distinction, we shall make a few general remarks upon each division before proceeding to the consideration of the individual preparations.

Conserves consist of undried vegetable substances and refined sugar beaten into a uniform mass. By means of the sugar, the vegetable matter is enabled to resist for some time the decomposition to which it would otherwise be exposed in the undried state, and the properties of the recent plant are thus retained to a certain extent unaltered. But, as active medicines even thus treated undergo some change, and those which lose their virtues by desiccation cannot be long preserved, the few conserves now retained are intended rather as convenient vehicles of other substances than for separate exhibition. The sugar used in their preparation should be reduced to a fine powder by pounding and sifting, as otherwise it will not mix uniformly with the other ingredients.

Electuaries are mixtures consisting of medicinal substances, especially dry powders, combined with syrup or honey, in order to render them less unpleasant to the taste, and more convenient for internal use. They are usually prepared extemporaneously; and it is only when their complex nature renders it convenient to keep them ready made, or some peculiarity in the mode of mixing the ingredients requires attention, that they become proper objects for official direction. Their consistence should not be so soft, on the one hand, as to allow the ingredients to separate, nor so firm, on the other, as to prevent them from being swallowed without mastication. Different substances require different proportions of syrup. Light vegetable powders usually require twice their weight, gum-resins two-thirds of their weight, resins somewhat less, mineral substances about half their weight, and deliquescent salts not more than one-tenth. Should the electuary be found, after having been kept for a short time, to swell up and emit gas, it should be beaten over again in a mortar, so that any portion of the sugar which may have crystallized may be again accurately incorporated with the other ingredients. Should it, on the contrary, become dry and hard from the mutual reaction of its constituents, more syrup should be added, so as to give it the requisite consistence. If the dryness result from the mere evaporation of the aqueous part, water should be added instead of syrup; and the same remark is applicable to the conserves. To prevent the hardening of electuaries, the French writers recommend the use of syrup prepared from brown sugar, which is less apt to crystallize than that made from the refined. Molasses would answer the same purpose, but its taste might be objectionable. Some employ honey, but this is not always acceptable to the stomach. Glycerin might sometimes be used with advantage.*

CONFECTIO PIPERIS. Br. Confection of Pepper.

(CON-FĔC'TI-Ō PĪ'PER-ĬS.)

Electuarium Piperis; Electuaire de Poivre, *Fr.*; Pfefferlatwerge, *G.*

"Black Pepper, in fine powder, 2 *ounces* (Imperial) or 40 grammes; Caraway Fruit, in fine powder, 3 *ounces* (Imp.) or 60 grammes; Clarified Honey, 15 *ounces* (Imp.) or 300 grammes. Mix." *Br.* This preparation was intended as a substitute for *Ward's paste*, which acquired some reputation in Great Britain as a remedy in piles and ulcers of the rectum. To do good,

* *Confectio Aromatica. Aromatic Confection.* (Electuarium Aromaticum; Electuaire, Confection aromatique, *Fr.*; Aromatische Latwerge, Gewürzlatwerge, *G.*) "Take of Aromatic Powder *four troyounces*; Clarified Honey *four troyounces*, or *a sufficient quantity*. Rub the Aromatic Powder with Clarified Honey until a uniform mass of the proper consistence is obtained." *U. S.* 1870. The aromatic confection has been abandoned in the U. S. and Br. Pharmacopœias, probably because readily prepared extemporaneously. It affords, nevertheless, a convenient means of administering the spices contained in it, and an agreeable vehicle for other medicines. The 1870 U. S. formula differed favorably from that of 1850 in the omission of the saffron; and the place of the syrup of orange peel has been economically supplied by using a larger proportion of honey. The confection is given in debilitated states of the stomach. The dose is from ten to sixty grains (0·65–3·9 Gm.).

Confectio Aurantii Corticis. Confection of Orange Peel. (Conserva Aurantii; Conserve d'Ecorce d'Orange, *Fr.*; Apfelsinenschalen-Conserve, *G.*) "Take of Sweet Orange Peel, recently separated from the fruit by grating, *twelve troyounces*; Sugar [refined] *thirty-six troyounces*. Beat the Orange Peel with the Sugar, gradually added, until they are thoroughly mixed." *U. S.* 1870. This confection, like the preceding, has been dropped in the U. S. and Br. Pharmacopœias. It is not used as frequently as it deserves to be. It is, when well made, a grateful aromatic vehicle or adjunct for tonic and purgative powders.

Confectio Opii. Confection of Opium, which was the modern substitute for the mediæval preparations known as *theriaca* and *mithridate*, has been finally dropped from both Pharmacopœias. One grain of opium was contained in about thirty-six grains of the former United States confection, and in about forty grains of the British. The following is the U. S. Pharmacopœia (1870) formula. "Take of Opium, in fine powder, *two hundred and seventy grains*; Aromatic Powder *six troyounces*; Clarified Honey *fourteen troyounces*. Rub the Opium with the Aromatic Powder, then add the Honey, and beat the whole together until thoroughly mixed."

it must be continued, according to Mr. Brodie, for two, three, or four months. The dose is from one to two drachms (3·9 to 7·8 Gm.), repeated two or three times a day. Its stimulating properties render it inapplicable to cases attended with much inflammation.

CONFECTIO ROSÆ. U. S. (Br.) Confection of Rose.

(CŌN-FĔC'TI-Ō RŌ'ZÆ.)

Confectio Rosæ Gallicæ, *Br.;* Confection of Roses; Conserva Rosarum; Conserve de Rose rouge, *Fr.;* Rosen-Conserve, *G.*

"Red Rose, in No. 60 powder, *eighty grammes* [or 2 ounces av., 360 grains]; Sugar, in fine powder, *six hundred and forty grammes* [or 22 ounces av., 252 grains]; Clarified Honey, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Stronger Rose Water, *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims]. Rub the Red Rose with the Stronger Rose Water previously heated to 65° C. (149° F.), then gradually add the Sugar and Honey, and beat the whole together until a uniform mass results." *U. S.*

"Fresh Red-Rose Petals, *one pound* (Imperial) or 500 grammes; Refined Sugar, *three pounds* (Imp.) or 1500 grammes. Beat together in a stone mortar." *Br.*

This preparation differs from that formerly official only in a slight increase—4 per cent.—in the quantity of sugar; this is rather an improvement.

In the British process the unblown petals only are used, and these should be deprived of their claws; in other words, the rose-buds should be cut off a short distance above their base, and the lower portion rejected. In the last four editions of the U. S. Pharmacopœia, dried roses have been substituted for the fresh, as the latter are not brought to our market. The process is very similar to that of the French Codex. We have been informed, however, that confection of rose is still made in Philadelphia on a large scale from the fresh petals of the hundred-leaved rose and others, by beating them into a pulp with sugar, as in the British process. An excuse for this deviation from the official formula is, that the confection thus made has greater adhesiveness than the official, and is therefore better fitted for the formation of pills. Confection of Rose is slightly astringent, but is used almost exclusively as a vehicle of other medicines, or to impart consistence to the pilular mass.

CONFECTIO SENNÆ. U. S., Br. Confection of Senna.

(CŌN-FĔC'TI-Ō SĔN'NÆ.)

Electuarium e Senna, *P. G.;* Electuarium de Senna Compositum, Electuarium Lenitivum; Electuaire de Séné composé, Electuaire lénitif, *Fr.;* Senna-Latwerge, *G.*

"Senna, in No. 60 powder, *one hundred grammes* [or 3 ounces av., 230 grains]; Cassia Fistula, bruised, *one hundred and sixty grammes* [or 5 ounces av., 281 grains]; Tamarind, *one hundred grammes* [or 3 ounces av., 230 grains]; Prune, sliced, *seventy grammes* [or 2 ounces av., 205 grains]; Fig, bruised, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sugar, in fine powder, *five hundred and fifty-five grammes* [or 19 ounces av., 252 grains]; Oil of Coriander, *five grammes* [or 77 grains]; Water, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Place the Cassia Fistula, Tamarind, Prune, and Fig in a close vessel with *five hundred cubic centimeters* [or 17 fluidounces] of Water, and digest for three hours, by means of a water-bath. Separate the coarser portions with the hand, and rub the pulpy mass, first through a coarse hair sieve, and then through a fine one, or through a muslin cloth. Mix the residue with *one hundred and fifty cubic centimeters* [or 5 fluidounces] of Water, and, having digested the mixture for a short time, treat it as before, and add the product to the pulpy mass first obtained. Then, by means of a water-bath, dissolve the Sugar in the pulpy liquid, and evaporate the whole, in a tared vessel, until it weighs *eight hundred and ninety-five grammes* [or 31 ounces av., 250 grains]. Lastly, add the Senna and the Oil of Coriander, and incorporate them thoroughly with the other ingredients while they are yet warm." *U. S.*

"Senna, in fine powder, 7 *ounces* (Imperial) or 140 grammes; Coriander Fruit, in fine powder, 3 *ounces* (Imp.) or 60 grammes; Figs, 12 *ounces* (Imp.) or 240 grammes; Tamarinds, 9 *ounces* (Imp.) or 180 grammes; Cassia Pulp, 9 *ounces* (Imp.) or 180 grammes; Prunes, 6 *ounces* (Imp.) or 120 grammes; Extract of Liquorice, 1 *ounce* (Imp.) or 20 grammes; Refined Sugar, 30 *ounces* (Imp.) or 600 grammes; Distilled Water, *a sufficient quantity*. Boil the Figs and Prunes gently with *twenty-four ounces* (Imp.) or four hundred and eighty grammes of Distilled Water in a covered vessel for four hours; add more Distilled Water to make up the

quantity to its original volume, and then incorporate the Tamarinds and Cassia Pulp; digest for two hours; rub the softened pulp of the fruits through a hair sieve, rejecting the seeds and other hard parts; to the pulp thus obtained add the Refined Sugar and Extract of Liquorice, dissolving them by the aid of gentle heat; while the mixture is still warm, add to it gradually the mixed Senna and Coriander powders; mix the whole thoroughly; make the weight of the resulting Confection *seventy-five ounces* (Imp.) or fifteen hundred grammes, either by evaporation or by the addition of more Distilled Water." *Br.*

The Confection of Senna, when correctly made, is an elegant preparation, and keeps well if properly protected. The present U. S. process differs from that of 1860 in preparing the pulps, as suggested in former editions of this Dispensatory, instead of taking them already prepared. The present preparation contains about 10 per cent. more sugar than that official in 1880. An improvement has been made in the process of the U. S. P. 1890 by replacing the coriander seed of the former Pharmacopœias with oil of coriander: it is almost impossible to powder coriander fine enough to avoid hard particles except by drying it to such an extent as to deprive it injuriously of its volatile oil, and the plan of using the oil directly has therefore been adopted. It was formerly not uncommon to omit the cassia pulp in this preparation, as the pods were not always to be found in the market; but, as this is next to senna the most active ingredient, the omission was to be regretted. Cassia fistula is now readily procured in commerce, and there can be no excuse for its omission. It has also been proposed to substitute the fluid extract of senna for the crude drug (*A. J. P.*, xliii. 123); but, as the fluid extract is of such uncertain quality, the leaves themselves are preferable.

A very good, pleasant laxative, admirably adapted to cases of habitual costiveness, especially in pregnant women and in persons affected with *piles*. Dose, two drachms (7·8 Gm.), at bedtime.

CONFECTIO SULPHURIS. Br. Confection of Sulphur.

(CǪN-FĔC'TI-Ō SŬL'PHŬ-RĬS.)

Electuarium Sulphuris; Electuaire de Soufre, *Fr.;* **Schwefel-Latwerge,** *G.*

"Sublimed Sulphur, 4 *ounces* (Imperial) or 100 grammes; Acid Potassium Tartrate, in powder, 1 *ounce* (Imp.) or 25 grammes; Tragacanth, in powder, 18 *grains* (Imp.) or 1 gramme; Syrup, 2 *fl. ounces* (Imp. meas.) or 50 cubic centimetres; Tincture of Orange, ½ *fl. ounce* (Imp. meas.) or 12·5 cubic centimetres; Glycerin, 1½ *fl. ounces* (Imp. meas.) or 37·5 cubic centimetres. Mix." *Br.*

This is merely a mode of administering the two laxatives, sulphur and potassium bitartrate; and the relative proportion of the latter is so small that it can have little effect. The addition of tragacanth is due to a suggestion of Mr. Peter Boa, who found that without it a syrupy layer of liquid formed on top of the confection. (*P. J. Tr.*, 1882, 682.) The syrup of orange peel, formerly directed, has been replaced in the Br. Pharm. (1898) by syrup and tincture of orange, evidently because the syrup of orange peel did not keep well, whilst the glycerin serves to retain the proper consistence of the confection. The dose is from one to two drachms (3·9 to 7·8 Gm.) or more.

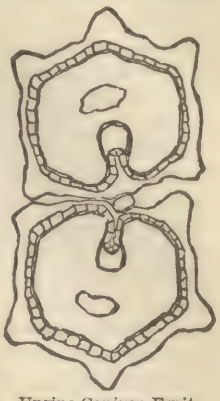
CONII FOLIA. Br. Hemlock Leaves.

(CǪ-NĪ'Ī FŌ'LI-Ą.)

"The fresh leaves and young branches of Conium maculatum, Linn, collected when the fruit begins to form." *Br.*

Hemlock Leaves; Herba Conii, *P.G.;* **Herba Cicutæ Majoris; Feuilles de grande Ciguë (de Ciguë officinale),** *Fr.;* **Schierlingskraut, Schierlings-Blätter,** *G.*

CONIUM. U. S. (Br.) Conium. [Hemlock.]



(CǪ-NĪ'ŬM.)

"The full-grown fruit of Conium maculatum, Linné (nat. ord. Umbelliferæ), gathered while yet green." *U. S.* "The dried, full-grown, unripe fruits of Conium maculatum, Linn." *Br.*

Conii Fructus, *Br.*, **Hemlock Fruit; Fruits de grande Ciguë, Ciguë ordinaire, Grande Ciguë,** *Fr.;* **Gefleckter Schierling, Schierlingsfrüchte,** *G.;* **Cicuta,** *It., Sp.*

Gen. Ch. Partial involucre halved, usually three-leaved. *Fruit* nearly globular, five-streaked, notched on both sides. *Willd.*

Conium maculatum. Willd. *Sp. Plant.* i. 1395; Bigelow, *Am. Med. Bot.* i. 113; Woodv. *Med. Bot.* p. 104, t. 42. This is an umbelliferous plant, having a biennial spindle-shaped whitish root, and an herbaceous branching stem, from three to six feet high, round, hollow, smooth, shining, slightly striated, and marked with brownish-purple spots. The lower leaves are tripinnate, more than a foot in length, shining, and attached to the joints of the stem by sheathing petioles; the upper are smaller, bipinnate, and inserted at the division of the branches; both have channelled footstalks, and incised leaflets, which are deep green on their upper surface and paler beneath. The flowers are very small, white, and disposed in compound terminal umbels. The general involucre consists of from three to seven lanceolate, reflected leaflets, whitish at their edges; the partial involucre, of three or four, oval, pointed, spreading, and on one side only. There are five petals, cordate, with their points inflected, and nearly equal. The stamens are spreading, and about as long as the corolla; the styles diverging. The fruit, commonly called seeds, is roundish-ovate, a line and a half or rather less in length by a line in breadth, striated, and composed of two plano-convex, easily separable parts, which have on their outer surface five crenated ribs separated by slightly wrinkled furrows. On cross-section the absence of oil-ducts becomes apparent, and a deep furrow upon the commissural face of the albumen gives a reniform appearance. As kept in the shops, the mericarps are usually separated. They are thus officially described: "About 3 Mm. long; broadly ovate; laterally compressed; grayish-green; often divided into the two mericarps, each with five crenate ribs, without oil-tubes, and containing a seed which is grooved on the face; odor and taste slight. When triturated with solution of potassium or sodium hydrate, Conium gives off a strong, disagreeable, mouse-like odor." *U. S.*

Unripe Conium Fruit, transverse section.

Conium is a native of Europe, and has become naturalized in the United States, where it is also cultivated for medicinal purposes. It grows usually in clusters along the roadsides or in waste grounds, and is found most abundantly near old settlements. It flowers in June and July. The whole plant, especially at this period, exhales a fetid odor, compared by some to that of mice, by others to that of the urine of cats; and narcotic effects result from breathing for a long time air loaded with the effluvia. The plant varies in narcotic power according to the weather and climate, being most active in hot and dry seasons and in warm countries. The hemlock of Greece, Italy, and Spain is said to be much more energetic than that of the north of Europe. As a rule, those plants are most active which grow in a sunny exposure. The term *cicuta*, which has often been applied to this plant, belongs to a different genus. The leaves and fruit are official. The proper season for gathering the leaves is when the plant is in flower; and Dr. Fothergill asserts, from experiment, that they are most active about the time that the flowers begin to fade. The footstalks* should be rejected, and the leaflets quickly dried, either in the hot sun, on tin plates before a fire, or by a stove-heat not exceeding 120° F. They should be kept in boxes or tin cases, excluded from the air and light, by exposure to which they lose their fine green color and become deteriorated. The same end is answered by pulverizing them, and preserving the powder in opaque and well-stopped bottles. But little reliance can be placed on the dried leaves, as, even when possessed of a strong odor and a fine green color, they may be destitute of the narcotic principle. When rubbed with caustic potassa they should exhale the odor of coniine. The fruit retains its activity much longer than the leaves. Dr. Christison found them to have sustained no diminution of power after having been kept eight years. Hirtz inferred from experiment that extract of the seeds was ten times stronger than that of the leaves. Commercial conium occasionally contains other umbelliferous plants, or it may be almost wholly composed of such plants, and even anise has been used as an adulteration to the fruit. The presence of such impurities is to be recognized by physical examination.

Properties. The dried leaves of the hemlock have a strong, heavy, narcotic odor, less disagreeable than that of the recent plant. Their taste is bitterish and nauseous; their color a dark green, which is retained in the powder. A slight degree of acrimony possessed by the fresh leaves is said to be dissipated by drying. The seeds have a yellowish-gray color, a feeble odor, and a bitterish taste. Their form has already been described. Water distilled from the

* Dr. Manlius Smith, of Manlius, N.Y., has demonstrated that the footstalks are almost destitute of the active alkaline principle. (*Ann. de Thérap.*, 1873, p. 39.)

fresh leaves has the odor of hemlock, and a nauseous taste, but does not produce narcotic effects. The decoction has little taste, and the extract resulting from its evaporation is nearly inert. From these facts it is inferable that the active principle, as it exists in the plant, is not volatile at 100° C. (212° F.), and, if soluble in water, is injured by a boiling heat. Alcohol and ether take up the narcotic properties of the leaves; and the ethereal extract, which is of a rich dark green color, is stated by Dr. A. T. Thomson to have the smell and taste of the plant in perfection, and in the dose of half a grain to produce headache and vertigo. Upon destructive distillation, the leaves yield a very poisonous empyreumatic oil. Geiger was the first who obtained the active principle in a separate state, and proved it to be alkaline. It appears that there are two volatile substances in hemlock; one of them an *oil*, which is in very small quantity, and is obtained by simple distillation; the other, the volatile alkaloid *coniine*, or *conine*, which is the active principle. As it exists in the plant in combination with an acid, it is not readily volatilized, but it freely comes over with the distillate when an alkali has been previously added. The acid of conium Peschier believed to be peculiar, and named *conïic acid*. Other observers assert that it is *malic acid*. Geiger obtained coniine by the following process. He distilled fresh hemlock with caustic potassa and water, neutralized with sulphuric acid the alkaline liquid which came over, evaporated this liquid to the consistence of syrup, added anhydrous alcohol so long as a precipitate of ammonium sulphate was afforded, separated this salt by filtration, distilled off the alcohol, mixed the residue with a strong solution of caustic potassa, and distilled anew. The coniine passed over with the water, from which it separated, floating on the surface in the form of a yellowish oil. According to Dr. Christison, an easier process is to distil cautiously a mixture of a strong solution of potassa and the alcoholic extract of the unripe fruit. Dr. J. Schorm suggests an improvement in the process, which yields a purer coniine, in *Ber. d. Deutsch. Chem. Ges.*, 1881, 1765; also *N. R.*, Dec 1881. As obtained by the above process, coniine is in the state of a hydrate, containing one-fourth of its weight of water and a little ammonia. From the former it may be freed by calcium chloride; from the latter, by exposing it under an exhausted receiver till it ceases to emit bubbles of gas.

The fresh leaves or seeds should be employed in the preparation of coniine, as the alkaloid undergoes decomposition by time and exposure. The seeds contain most of this principle; but even in these it exists in very small proportion. From 6 pounds of the fresh and 9 of the dried seeds, Geiger obtained about an ounce of coniine; while from 100 pounds of the fresh herb he got only a drachm, and from the dried leaves none. Christison recommends the full-grown fruit while yet green, and states that 8 pounds will yield half an ounce of coniine hydrate, and contain much more. In relation to the relative strength of different parts of the plant, Dr. Manlius Smith, of New York, gives as the result of a series of carefully conducted experiments that the unripe fruit of the conium is far preferable to the dried leaves, and is even stronger than the full-grown fruit, that it may be dried without serious injury, and that a very active preparation may be made from it. He also found that full-grown fruit collected in August, and dried in the dark, retained its activity unimpaired for several years. This would appear to contradict in some measure previous opinions of the injurious effects of time. (*P. J. Tr.*, Feb. 1869, 491–2.) Farr and Wright (*P. J. Tr.*, 1896, 273) confirm the views of Dr. Harley and Manlius Smith, and affirm that green fruits are alone reliable. For a method of assaying conium fruit, by Schwickerath, see *Pharm. Record*, 1893, 282.

Coniine, $C_8H_{17}N$, has been thoroughly studied by Hofmann (1881), who established the correct formula as given, instead of $C_8H_{15}N$, as it was formerly assumed, and Ladenburg (1886), who effected its synthesis from *allyl pyridine* by reduction with sodium in alcoholic solution: $C_5H_4(C_3H_5)N + 8H = C_5H_{10}(C_3H_7)N$. This reaction gives *a-normal propyl piperidine*, which is optically inactive, but by the crystallization of its tartrate splits into *coniine* (dextro-rotatory) and a very similar lævo-rotatory coniine, just as racemic acid splits into dextro-rotatory and lævo-rotatory tartaric acid.

Coniine is in the form of a yellowish oily liquid, of sp. gr. 0·862, of a very acrid taste, and a strong penetrating odor, compared to that of the urine of mice, and recalling the smell of fresh hemlock, though not identical with it. In volatility it resembles the essential oils, readily rising with the vapor of boiling water, but when unmixed requiring for ebullition a temperature of 166° C. (330·8° F.). It is freely soluble in alcohol, ether, and the fixed and volatile oils, and slightly so in water. It unites with about one-fourth of its weight of water to form a hydrate. It reddens turmeric, and neutralizes the acids, forming with them soluble salts, some of which are crystallizable. With tannic acid it forms an insoluble compound. Like am-

monia, it occasions a white cloud when approached by a rod moistened with hydrochloric acid; and the resulting hydrochloride is crystallizable, and not in the least deliquescent. The hydrochloride may also be obtained as a brilliant crystalline mass by dissolving coniine in anhydrous ether and passing dry hydrochloric acid gas through the solution. The salt is very soluble in water and alcohol but insoluble in ether. It can be heated to 90° C. without decomposition, and melts at 218° C. Coniine coagulates albumen, and precipitates the salts of aluminum, copper, zinc, manganese, and iron. It also precipitates silver nitrate, but in excess redissolves the precipitate. Most of its salts are decomposed by evaporation. When exposed to the air, it speedily assumes a deep brown color, and is ultimately converted into a resinous matter, and into ammonia, which escapes. Under the influence of heat this change takes place with much greater rapidity. The presence of coniine may be detected in an extract or other preparation of hemlock by rubbing it with potassa, which instantly develops its peculiar odor.* It is a most energetic poison.

In association with coniine in the hemlock are found also the following bases:

Ethyl-piperidine, $C_7H_{15}N$ or $C_5H_9(C_2H_5)N$.

Methyl-coniine, $C_9H_{19}N$ or $C_5H_9(C_3H_7)N(CH_3)$.

Conhydrine, $C_8H_{17}NO$ or $C_5H_9(CHOH.CH_2.CH_3)NH$.

Pseudo-conhydrine, $C_8H_{17}NO$ or $C_5H_9(CH_3.CH_2OH.CH)NH$.

Methyl-coniine, first obtained by Kekulé and Von Planta in commercial coniine, is of minor importance.

Conhydrine is crystallizable, fusible below 100° C. (212° F.), and volatilizable at a higher temperature, diffusing the peculiar odor of coniine, or one very much like it. Water dissolves it considerably, ether and alcohol freely; and the solution has a strong alkaline reaction. Its formula is given as $C_8H_{17}NO$. When distilled with anhydrous phosphoric oxide it splits into coniine and one molecule of water. (*A. J. P.*, xxix. 321.) It may be separated from coniine by exposing the mixed alkaloids to a freezing mixture, expressing, and then repeatedly crystallizing from ether. (*Gmelin*, xiii. 169.) E. Merck obtained a small quantity of a new alkaloid from the high-boiling portion of crude coniine. The isolation was accomplished by fractional distillation *in vacuo* and recrystallization. The alkaloid crystallizes in needles, is easily soluble in water, alcohol, ether, benzene, and chloroform, fuses at about 98° C., and boils at 230°–232° C. According to Ladenburg, the alkaloid is an isomer of conhydrine, having the formula $C_8H_{17}NO$, and for this reason the name *pseudo-conhydrine* was selected. (*Chem. Centralbl.*, 1891, 414; see also *P. J. Tr.*, 1891, 1170.)

Paraconiine. Coniine was supposed to have been artificially produced by Hugo Schiff. From the reaction of *butyric aldehyde* with an alcoholic solution of ammonia, he obtained two bases, one of which, *dibutyraldine*, yielded, on distillation, first a neutral oily substance, and afterwards a strong alkaline base, which proved to have the physiological properties of natural coniine, but was optically inactive, while true coniine is dextro-rotatory. Since the change in the formula of true coniine it will be seen that the base *paraconiine*, which is $C_8H_{15}N$, is not even isomeric with coniine.

Medical Properties and Uses. Hemlock is supposed to be the narcotic used by the Athenians to destroy the life of condemned individuals, and by which Socrates and Phocion died. It was also used by the ancients as a medicine, but fell into entire neglect, and did not again come into notice till the time of Störck, by whom it was much employed and extravagantly praised. Though fatal to some animals, hemlock is eaten with impunity by others, as horses, goats, and sheep. Anodyne, soporific, antispasmodic, antaphrodisiac, deobstruent, and diuretic properties have been ascribed to it. It was highly recommended by Störck as a remedy in *scirrhus* and *cancerous ulcers*, and has since been employed in all kinds of chronic enlargements, and in diseases most numerous and most diverse.

Modern research has, however, greatly limited the use of the medicine, rendering its possession of alterative properties extremely doubtful. When taken internally in sufficient dose it produces very profound muscular weakness, associated, it may be, with vertigo and disordered vision. After toxic doses the muscular prostration is extreme, the eyelids droop from weak-

* Orfila gives the following additional chemical characters of coniine. Heated in a capsule, it forms white vapors *having a strong smell of celery and of the urine of mice.* Weak tincture of iodine gives a white precipitate, becoming olive with excess of the tincture. *Pure concentrated sulphuric acid does not alter it;* but when the mixture is heated, it becomes first brown, then blood-red, and finally black. *Nitric acid imparts a topaz color*, not changed by heat. Platinum and gold chlorides give yellow precipitates, and corrosive sublimate a white one. Potassium permanganate is immediately decolorized. *Neutral lead acetate gives no precipitate*, nor does the subacetate. The parts of this note in italics indicate the means of distinguishing this alkaloid from nicotine. (See *P. J. Tr.*, xi. 89.)

ness, the voice is suppressed, the pupils dilated, the sight almost lost; consciousness is usually preserved to the last, and life finally is extinguished without struggle. In some cases there have been convulsive movements, and violent cardiac palpitation has been noted. The chief action of the poison is upon the motor nerves, which it paralyzes; the efferent or sensitive nerves are also affected, but to a much less extent. Conium probably exerts no direct influence upon the cerebral centres, but there is some reason for believing that it is a spinal depressant. At present conium is rarely employed by the general practitioner, except in spasmodic affections, such as *chorea* and *whooping-cough*. Probably the most frequent use of it is by alienists for the production of calm in maniacal excitement.

The juice of the fresh leaves of conium is much used in England, but the fluid extract of the U. S. Pharmacopœia, made from the fruit, is the best of all preparations. The powdered leaves may be given in the dose of three or four grains (0·20–0·26 Gm.) twice a day, gradually increased till the occurrence of slight vertigo or nausea indicates that it has taken effect. To maintain a given impression, it is necessary to increase the dose even more rapidly than is customary with most other narcotics, as the system becomes very speedily habituated to its influence. In some instances the quantity administered in one day has been augmented to more than two ounces. The strength of the preparations of hemlock is exceedingly unequal; and caution is therefore necessary, when the medicine is given in very large quantities, to employ the same parcel, or, if a change be made, to commence with the new parcel in small doses, so as to obviate any danger which might result from its greater power. Unpleasant consequences have followed a neglect of this precaution. There are also an official tincture, a fluid extract, and an alcoholic extract, all of which, when properly made, are considered efficient preparations. The expressed juice of the fresh plant, with a little alcohol for its preservation, is one of the most reliable forms in which the leaves can be used. The powdered seeds should be given in a dose considerably smaller than that of the leaves.* The fresh leaves are sometimes used externally as an anodyne cataplasm; and the extract, and an ointment prepared from the leaves, are applied to the same purpose. A plaster made from the extract has also been employed.†

Coniine acts precisely as does hemlock, and may be used for the same purposes. The dose is from one-fourth to one-half drop (0·015 to 0·03 C.c.). A solution of one part in one hundred of very dilute alcohol has been used with advantage in certain cases of *scrofulous ophthalmia* with photophobia, applied several times daily by friction about the eyelids. (*Journ. de Pharm.*, 3e sér., xix. 219.) Prof. Mauthner, of Vienna, recommends it especially in the spasmodic contraction of the orbicularis oculi in scrofulous children, using a solution containing half a grain of coniine in a drachm of almond oil, which he applies by a pencil to the eyelids twice or thrice daily. As a collyrium, from one to three drops may be added to six drachms of pure water, and two drachms of mucilage of quince seeds, the whole being carefully strained.

Coniine hydrochlorate has been recommended for exhibition by Mr. G. C. Close, as preferable to the uncombined alkaloid. From half a grain he experienced no sensible effects; but a grain produced the characteristic symptoms of coniine in an even unpleasant degree. These doses are probably dangerous, and not more than a sixth of a grain (0·01 Gm.) should be given as a commencing dose. (*A. J. P.*, 1869, p. 62.) Dr. Harley has prepared an acid *coniine benzoate* by adding two mols. of the acid to one of the base, and found the resulting salt effectual in the dose of half a grain. (*P. J. Tr.*, Jan. 1871, p. 585.) According to Mourrut, one of the best crystallizable salts of coniine is the *bromhydrate*. The alkaloid is treated with aqueous bromhydric acid, which causes, especially with the brown variety of coniine, an elevation of temperature, and a disengagement of white fumes of the odor of coniine; the mixture then turns green, and finally blackish red. The crystals, which form after some time, may be obtained quite colorless by repeated crystallizations. They are colorless prismatic needles, soluble in water and alcohol, less so in ether and chloroform, inodorous and almost tasteless, and are not deliquescent. They should be kept in the dark, otherwise they assume a red tint. The salt has been used by various practitioners with great success in the treatment of *whooping-cough*, in

* The root, while containing a small proportion of coniine, is too feeble, according to the experiments of Dr. John Harley, of London, to be used practically with advantage. Dr. Harley has found in the root three new proximate principles, one a very bitter resin, which he names *conamarine*, and the two others crystallizable bodies, named respectively *rhizoconin* and *rhizoconolein*. They are all neutral, and, so far as known, medicinally inert. (See *P. J. Tr.*, Aug. 1867.)

† The following formula of Planche has been approved by the Society of Pharmacy of Paris. Take of extract of hemlock 90 parts, of purified elemi 20 parts, of white wax 10 parts. Melt the resin and wax with a gentle heat, and incorporate the extract with the mixture. (*Journ. de Pharm.*, Juillet, 1862, p. 46.)

doses of about one-twelfth of a grain (·005 Gm.), if necessary, every hour, for a child three years of age; or one-thirtieth of a grain (·002 Gm.) for a child of one year; or one-sixth of a grain (·01 Gm.) for adults. In *sciatica* it has been employed hypodermically in quantities of one-twelfth of a grain (·005 Gm.) with good results. (*Répert. de Pharm.*, 1876, p. 369; *N. R.*, 1876, 1879, pp. 18, 178.) *

CONVALLARIA. U. S. Convallaria.

(CŌN-VĂL-LĀ'RĮ-Ą.)

"The rhizome and roots of Convallaria majalis, Linné (nat. ord. Liliaceæ)." *U. S.*

Lily of the Valley; Lilium Convallium; Muguet, *Fr.*; Maiblumen, *G.*

Gen. Ch. Perianth bell-shaped (white), six-lobed, deciduous; the lobes recurved. Stamens six, included, inserted on the base of the perianth; anthers introrse. Ovary three-celled, tapering into a stout style; stigma triangular. Ovules four to six in each cell. Berry few-seeded (red). *Gray.*

The ordinary lily of the valley of the gardens is a low, perennial herb, having slender running root-stocks, which send up each spring from the scaly sheathing bud two oblong, bright green, smooth leaves, whose long sheathing petioles are so enrolled as to appear like a stalk, and producing in late spring or early summer a one-sided raceme of beautiful, sweet-scented, nodding, bell-shaped flowers, placed upon an angular scape. It is primarily a native of Europe, but may be found in America escaped from gardens, and a plant which grows wild in the higher Alleghanies from Central Virginia to South Carolina seems to be identical with it. The root-stock of the lily of the valley occurs in pieces two to three inches long, covered with a mass of contorted, fine, almost fibrous rootlets. It is much thicker at one end, to which are attached the remains of the petioles and scape, and rapidly or sometimes almost abruptly tapers towards the smaller end. The long end is much gnarled and wrinkled, with leaf-scars. It is officially described as "of horizontal growth and somewhat branched, about 3 Mm. thick, cylindrical, wrinkled, whitish, marked with few circular scars; at the annulate joint with about eight or ten long, thin roots; fracture somewhat fibrous, white; odor peculiar, pleasant; taste sweetish, bitter, and somewhat acrid." *U. S.* G. F. Walz found in lily of the valley *convallarin* and *convallamarin*. (*A. J. P.*, 1859, p. 577.) Convallarin is in colorless rectangular prisms, scarcely soluble in water, but sufficiently so to render the solution acrid and to cause it when shaken to foam like soap and water. It is easily dissolved by alcohol. Its composition is represented by the formula $C_{34}H_{62}O_{11}$, and it is decomposed by long boiling with dilute acids into sugar and *convallaretin*. It is a glucoside. Convallamarin is a white powder, very bitter and afterwards sweetish, soluble in water and alcohol, but not in ether. This also is a glucoside. Its composition is $C_{23}H_{44}O_{12}$, and it is decomposed by heating with dilute sulphuric acid into sugar and *convallamaretin*. For preparing convallamarin Tanret modifies Walz's method, as follows. An alcoholic tincture made from the whole plant is precipitated with lead subacetate and filtered; the excess of lead is removed with dilute sulphuric acid, avoiding the use of more than is necessary, and, after neutralizing, the tincture is distilled, the last portion of alcohol being driven off in the open air; then the cooled and filtered liquor is treated with tannin, care being taken to keep the liquid neutral by cautiously adding a dilute solution of sodium carbonate. A compound of tannin and convallamarin is precipitated, which, after washing, is dissolved in 60° alcohol, the solution decolorized with charcoal, decomposed with zinc oxide, filtered, and evaporated to dryness. In this way convallamarin is obtained nearly white, and having the appearance of ordinary digitalin. To free it from the salts that are sometimes carried down by the tannin

* Dr. Harley's experiments on the relative value of the different preparations of conium are based upon their physiological effects. The results obtained were as follows. 1. The Extractum Conii, *B. P.*, and Succus Conii, *B. P.*—20 grains of the extract equalled 2 fluidrachms of the juice (10 gr. to f℥j). 4. Succus Conii, *B. P.*; Tincture of the green fruit (London ℥v in ℥xx): four drachms of the juice equalled fifty minims of the tincture (℥iv to ♏50). 11. Different preparations of Succus, *B. P.*, prepared by different persons,—Buckle's (the plant yielding 75 per cent. of juice) and Hanbury's (the plant yielding 35 per cent. of juice): nine drachms of Buckle's equalled three drachms of Hanbury's (℥ix to ℥iij). 12. Extract of green fruit, Tincture of green fruit, and Succus, *B. P.*—Three grains of the extract equalled four fluidrachms of the Tincture, and four drachms of Succus (gr. iij of extract = f℥iv of Tincture, and ℥iv of Succus). 14. Of *Squibb's fluid extract* 50 minims equal of the *Tinct.* of the *green fruit*, London, ℥iss; of the Succus Conii, *B. P.*, ℥v; of the Tincture of the fresh plant, ℥iiiss to ℥iv; and of the Tincture of the dry plant, f℥j. 15. Of Squibb's fluid extract ℥j equals of pale Succus ℥vi, of dark Succus ℥ij; of Tincture of the green fruit ℥iss; of Tincture of the fresh plant ℥iv; Neutral Coniine Benzoate, gr. ¾. 18. Of Succus Conii, *B. P.* (Buckle's), ℥vj = Coniine Benzoate, gr. ½. The author draws the following conclusions from his experiments. The green fruit, as the basis of Tinctures and Extracts, is decidedly superior to any other part of the plant; and the spirituous extract of the green fruit should be substituted for the almost worthless Extract of the Br. Pharm. The variable strength of the Succus is an objection. (*P. J. Tr.*, Jan. 1871, p. 585.)

precipitate, it is a good plan to redissolve it in 90° alcohol, filter, and then evaporate. One kilogramme of the fresh plant collected in the first days of August yielded two grammes of convallamarin. (*P. J. Tr.*, 1882, p. 423.) Taken internally the flowers are said to be emetic and cathartic, and their extract purges actively in the dose of half a drachm. They were formerly used in *epilepsy* and against *worms*. The *root*, which is also bitter, has similar purgative properties, and in powder is said to be sternutatory.

Medical Properties. The lily of the valley is stated to have been long used in Russia for the relief of *dropsy*, and in 1880 Drs. Troitzky and Bojojawlewsky commended it highly to the notice of the profession in valvular *heart disease*. The effects on the system of convallarin and convallamarin have been investigated by Dr. H. Marmé, of Germany, with the following results. *Convallarin*, in doses of 3 or 4 grains, acts as a purgative without observable inconvenience to the animals acted on; *convallamarin*, even in small doses, produces active vomiting, whether given by the mouth or injected into the subcutaneous tissue or directly into the veins. The latter principle acts especially on the heart, at first diminishing the number of its pulsations, and afterwards rendering them more frequent and irregular, and causing death in a few minutes after the introduction of the poison. The heart appears to be paralyzed, and cannot be excited after death. The principle acts on the heart through the vagi nerves. From 6 to 8 milligrammes (one-tenth to one-eighth of a grain) cause death when injected into the cervical vein in rabbits. (*N. Y. Med. Journ.*, 1867; *Schmidt's Jahrbuch.*, 1867, v.) The physiological action of convallarin has been investigated by a number of observers, with contrary results. Prof. Sée finds that in the dog it slows the action of the heart and increases the blood-pressure decidedly; whilst Leubuscher states that in no doses whatever does it elevate the arterial pressure. Ott, Coze, and Simon find that the heart is arrested in systole; Sée, that the arrest is diastolic; whilst Löwenthal, using the same preparation in exactly the same manner and dose upon different animals of the same species, obtained diverse results. Nathanson asserts that the confusion is largely due to the impurity and lack of genuineness in the products used; even Dr. Merck having admitted the impurity of his commercial convallamarin. Nathanson found that convallarin produced in man, when given in doses of 0·06 to 0·12 gramme, three or four times daily, only nausea, diarrhœa, and gastric pain; while convallamarin administered in daily amounts, gradually increasing from 0·03 to 0·3 gramme, reduced the rate of the pulse and markedly increased the flow of urine, only in very rare cases causing nausea or vomiting. In cardiac dropsy Sée gives, of an aqueous extract of the whole plant, 15 to 23 grains a day; Bojojawlewsky each day 50 to 100 grains of the plant in infusion. (See *Extractum Convallariæ Fluidum.*)

COPAIBA. U. S., Br. Copaiba. [Balsam of Copaiba.]

(CŌ-PĀ'I-BA.)

"The oleoresin of Copaiba Langsdorffii (Desfontaines), O. Kuntze, and of other species of Copaiba* (nat. ord. Leguminosæ)." *U. S.* "The oleo-resin obtained from the trunk of Copaifera Lansdorfii, Desf., and other species of Copaifera, Linn." *Br.*

Balsamum Copaiva, *P. G.;* Balsam Copaiba, Balsam Capivi; Copahu, Oleo-résine (Baume) de Copahu, *Fr.;* Copaiva; Copaiva-Balsam, *G.;* Balsamo di Copaiba, *It.;* Balsamo de Copayva, *Sp.*

Gen. Ch. Calyx none. *Petals* four. *Legume* ovate. *Seed* one, with an ovate arillus. *Willd.*

Copaiba was first noticed in a work published by Purchas, in England, in 1625. The next reference to it was by Cristoval d'Acuña, in 1638. In 1648, Marcgraf and Piso gave a detailed account of the tree which produces it, and the methods of gathering it. Jacquin in 1763 described a species of Copaifera, growing in Martinique, which he named *C. officinalis*. As this was believed to be the same plant with the one observed by Marcgraf in Brazil, it was adopted in the Pharmacopœias; but their identity was denied; and Desfontaines proposed for Jacquin's species the title of *C. jacquini*, in honor of that botanist. It is now known that many species of Copaifera exist in Brazil and other parts of South America; and all of them, according to Martius, yield copaiba. Besides *C. officinalis* or *C. jacquini*, the following are described by Hayne: *C. guianensis*, *C. langsdorffii*, *C. coriacea*, *C. beyrichii*, *C. martii*, *C. bijuga*, *C. nitida*, *C. laxa*, *C. cordifolia*, *C. jussieui*, *C. sellowii*, *C. oblongifolia*, and *C. multijuga*. Hayne believed that *C. bijuga* was the plant seen by Marcgraf and Piso. The four species to which in the Pharmacographia the production of copaiba is especially attributed are *C. officinalis*, L., *C. guianensis*, Desf., *C. coriacea*, Mart., and *C. langsdorffii*.

* The change of the generic name from Copaifera to Copaiba is another sacrifice to botanical reform. Prof. H. H. Rusby very properly says that this reform, as embodied in Kuntze's *Revisio Generum*, "will cause complete confusion." The generic records are said to be as follows: Copaiba, Mill., *Gard. Dict.* (1739); Copaiva, L., *Mat. Med.* (1749), *fide* O. Kuntze; Copaifera, L., *Gen.* (1762), *fide* O. Kuntze.

C. officinalis is a native of Venezuela, and grows in the province of Carthagena, mingled with the trees which afford the balsam of Tolu. It grows also in some of the West India islands, particularly Trinidad and Martinique. Though recognized in former editions of the U. S. Pharmacopœia as a source of copaiba, it probably yields little of that now in use. According to Hayne (x. t. 17 f. c.), the species from which most of the copaiba of commerce is derived is *C. multijuga*, growing in the Brazilian province of Para. It was recognized by the U. S. P. 1870; but Bentham, after examining the only specimens extant, asserts it not to be a Copaifera at all. It is probable that *C. guianensis*, which inhabits the neighboring territory of Guiana, especially in the vicinity of the Rio Negro, affords also considerable quantities; and *C. langsdorffii* and *C. coriacea*, which are natives of the province of São Paulo, are thought to yield most of the juice collected in that section of Brazil. *C. nitida*, inhabiting the province of Minas Geraes, probably also contributes to the commercial supplies through the port of Rio Janeiro.

The juice is obtained by making a square chamber in the stems of the trees, reaching to the very centre; and the operation is said to be repeated several times during the same season. It is asserted that a single tree will yield about eighty-four English Imperial pints. As it flows from the wound, it is clear, colorless, and very thin, but it soon acquires a thicker consistence, and a yellowish tinge. It is most largely collected in the provinces of Para and Maranham, in Brazil, and is brought to this country from the port of Para, in small casks or barrels. Large quantities of it come from Maracaibo, in Venezuela, and from other ports on the Caribbean Sea, whence it is brought in casks, demijohns, cans, jugs, etc. The drug is also exported from Angostura, Cayenne, Rio Janeiro, and some of the West India islands. African copaiba, from West Africa, appeared in the London markets in 1891. (See *P. J. Tr.*, 1891, 449; 1893, 215.)

Properties. Copaiba is a clear, transparent liquid, usually of the consistence of olive oil, of a pale yellow color, a peculiar not unpleasant odor, and a bitterish, hot, nauseous taste. Its sp. gr. varies ordinarily from 0·950 to 1·000, but has been known to be as low as 0·916. (Procter, *A. J. P.*, xxii. 292;* "from 0·916 to 0·993." *Br.*) It is insoluble in water, but entirely soluble in absolute alcohol, ether, and the fixed and volatile oils. Strong alkaline solutions dissolve it perfectly; but the resulting solution becomes turbid when largely diluted with water. With the alkalies and alkaline earths it forms saponaceous compounds, in which the resin of the copaiba acts the part of an acid. It dissolves magnesia, especially with the aid of heat, and even disengages carbonic acid from the carbonate of that earth. If triturated with a sixteenth of its weight of magnesia and set aside, it gradually assumes a solid consistence; and a similar change is produced with calcium hydrate. (See *Massa Copaibæ.*) Its essential constituents are volatile oil and resin, with at times small quantities of acids. As it contains no benzoic acid, it cannot with propriety retain its old title of *balsam of copaiva*. The substances which it most closely resembles, both in composition and in properties, are the turpentines. (See *Oleum Copaibæ.*) For a description of an apparatus for distilling the volatile oil, see a paper by R. A. Cripps in *Chemist and Druggist*, 1892, 282. Cripps found commercial copaiba to contain the following percentages of volatile oil: 40·95, 45, 45·3, 46·4, 47·8, 48·2, 49·6, 50·4, 50·8, 53·3, 59·6. J. C. Umney (*A. J. P.*, 1893, 544) found in African copaiba 39 per cent. of an oil of 0·918 specific gravity and with a rotation of + 20° 42′, the last character distinguishing it from the other varieties which yield lævo-rotatory oils.

"A transparent or translucent, more or less viscid liquid, of a pale yellow to brownish-yellow color, having a peculiar, aromatic odor, and a bitter and acrid taste. Specific gravity: 0·940 to 0·990 at 15° C. (59° F.). Insoluble in water; readily soluble in absolute alcohol, ether, chloroform, carbon disulphide, benzin, and fixed and volatile oils. It yields a transparent mixture with one-third of its volume of ammonia water. When Copaiba is heated, it should not evolve the odor of *turpentine*. When the volatile oil has been completely driven off by heating Copaiba in a flat-bottomed capsule, the residue, when cold, should be amorphous, transparent, and friable (absence of *fixed oils*). Copaiba should not be fluorescent, and, when heated to 130° C. (266° F.), it should not become gelatinous. On adding 1 drop of

* The variety of copaiba found by Prof. Procter to have this low sp. gr. was supposed to be from Para. It was of a light straw color, very fluid, and possessed of the pure copaiba odor. It contained 80 per cent. of volatile oil and 20 of resin, and was not affected by recently calcined magnesia. It appears to be the same with a variety described by Dr. L. Posselt in the *Chemical Gazette* for May 1, 1849. The view of Prof. Procter that it is the product of young trees, in which the juice has not become fully elaborated, is highly probable. As the virtues of copaiba depend mainly on the oil, this variety should be more efficacious than the copaiba in common use.

Copaiba to 19 drops of carbon disulphide, and shaking the mixture with 1 drop of a cold mixture of equal parts of nitric and sulphuric acids, it should not acquire a purplish-red or violet color (absence of *gurjun balsam*)." *U. S.* "The volatile oil should be present to the extent of at least 40 per cent., should rotate the plane of a ray of polarized light from 28° to 34° to the left (absence of African copaiba), and should not boil under 482° F. (250° C.)." *Br.*

The *resinous* mass which remains after the distillation of the oil is hard, brittle, translucent, greenish brown, and nearly destitute of smell and taste. By mixing it with the oil in proper proportion, we may obtain a liquid identical or nearly so with the original juice. This resinous mass is of an acid character, and yields a series of amorphous salts. It may be obtained pure by exposing a mixture of 9 parts of copaiba and 2 parts of aqueous ammonia (sp. gr. 0·95) to a temperature of 10° C. In this way crystals of *copaivic acid*, $C_{20}H_{30}O_2$, are obtained. This acid agrees with the *abietic acid* of colophony in composition, but not in properties. Copaivic acid is readily soluble in alcohol, and especially in warmed copaiba itself; much less in ether. When recrystallized from alcohol, copaivic acid fuses at 116°–117° C. (241°–242·6° F.). (*A. J. P.*, 1879, p. 305.) An analogous substance, *oxycopaivic acid*, $C_{20}H_{28}O_3$, was found in 1841 by H. von Fehling in Para copaiba; and Strauss in 1865 extracted *metacopaivic acid*, $C_{22}H_{34}O_4$, from Maracaibo copaiba. Copaivic acid forms crystallizable salts with alkalies, and *sodium copaivate*, $NaC_{20}H_{29}O_2$, made by combining molecular quantities of the acid and soda, is asserted by Zlamál and Roquette to be more efficient than any other preparation of copaiba. A *miscible copaiba* proposed by Groves was made by treating copaiba with a saturated solution of potassium carbonate. It resembled ordinary copaiba in appearance and consistence, but was alkaline, and when shaken with water, instead of floating on the surface, readily formed a white emulsion, more or less stable according to the degree of dilution. (*P. J. Tr.*, ix. 195.)

Copaiba, upon exposure to the air, acquires a deeper color, a thicker consistence, and greater density, and, if spread out upon an extended surface, ultimately becomes dry and brittle. This change is owing partly to the volatilization and partly to the oxidation of the essential oil. As it is the soft resin that results from the oxidation of the oil, it follows that the proportion of this resin increases with age. Considerable diversity must, therefore, exist in the drug, both in physical properties and in the properties of its ingredients, according to its age and degree of exposure. Similar differences also exist in the copaiba procured from different sources. Thus, that of the *West Indies*, when compared with the *Brazilian*, which is the variety above described, and in common use, is of a thicker consistence, of a deeper or darker yellow color, less transparent, and of a less agreeable, more terebinthinate odor; and specimens obtained from the ports of Venezuela or Colombia were found, upon examination by M. Vigne, to differ from each other not only in physical properties, but also in their chemical relations. (*Journ. de Pharm.*, N. S., i. 52.) The same is true, as observed by M. Buignet, of their action on polarized light, in which they differ not only in degree, but sometimes also even in direction. (*Journ. de Pharm.*, Oct. 1861, pp. 266–7.) It is not impossible that differences may exist in the juice according to the circumstances of its collection. The species of Copaifera from which the juice is collected, as well as the age of the tree, its position, and the season of collection, must also have influence over the product. It is highly probable that the resinous matter results from oxidation of the oil in the cells of the plant, and that the less elaborated the juice may be, the larger proportion it will contain of the oil. It is said that a volatile oil flows abundantly from a tree near Bogota, which is employed to adulterate the copaiba collected in that vicinity and shipped from Maracaibo and other neighboring ports.

Adulterations. Copaiba is often adulterated* with a fixed oil, especially castor oil, which, in consequence of its solubility, cannot, like the others, be detected by alcohol. Various plans have been proposed for recognizing the castor oil. The simplest is to boil a drachm of the copaiba in a pint of water till the liquid is wholly evaporated. If the copaiba contain a fixed oil, the residue will be more or less soft, according to the quantity present; otherwise it will be hard. Magnesium carbonate, caustic potassa, and sulphuric acid have also been proposed as tests. In the late Edinburgh Pharmacopœia it was stated that copaiba "dissolves a fourth part of its weight of magnesium carbonate, with the aid of a gentle heat, and continues translucent." The presence of a small proportion of any fixed oil renders the mixture opaque. One part of

* Some years since, a substance was imported into New York, under the name of *red copaiba*, which did not possess a single characteristic of the genuine drug. It was of a thick, semi-fluid consistence, not unlike that of balsam of Tolu, as it often reaches us, of a brown color similar to that of the same balsam, though darker, and of an unpleasant yet somewhat aromatic odor, recalling that of liquidambar, but less agreeable. Its origin is unknown.

potassa dissolved in two of water forms a clear solution with nine parts of pure copaiba, and the liquid continues clear when moderately diluted with water or alcohol; but the presence of one-sixth of fixed oil in the copaiba occasions more or less opacity in the liquid, and half the quantity causes the precipitation of white flakes in a few hours. (*Stolze.*) Turpentine, which is said to be sometimes added to copaiba, may be detected by its smell, especially if the copaiba be heated. According to Mr. Redwood, most of the proposed tests of the purity of copaiba are liable to fallacy; and the best measure of its activity is the quantity of volatile oil it affords by distillation. Castor oil, Venice turpentine, linseed oil, or gurjun balsam may be detected by means of petroleum benzin, which makes a clear solution with pure copaiba, but if either of the substances mentioned be present a milky mixture, which soon settles into two layers, is formed, the copaiba solution being on top (*A. J. P.*, July, 1873; *Proc. A. P. A.*, xxiv. 191, xxvi. 286). Prof. Maisch has found that *ten* volumes of benzin, instead of *three* as proposed by Prof. Wayne, must be added to one of copaiba to get the best results from this test. Indeed, it has been shown that pure copaiba will sometimes show turbidity when mixed with benzin. (*A. J. P.*, 1877, p. 131.) Hager recommends the use of absolute alcohol, which he says completely dissolves, without turbidity, all the varieties of copaiba except the Para, whose solution on standing clears itself by the deposition of a few white flakes. J. M. Fulton asserts that some pure copaibas are not entirely dissolved by absolute alcohol. (*A. J. P.*, 1877.) For additional tests and criticisms by Beckurts and Brueche, see *Arch. d. Pharm.*, 1891, p. 90; also *Proc. Amer. Pharm. Assoc.*, 1892, 635. For Hager's test, see *Chem. and Drug.*, 1894, 740. Dodge and Olcott (*Amer. Drug.*, 1895, 5) describe a test to detect gurjun balsam in copaiba, which Kebler regards as the most reliable yet proposed; it is as follows. Four drops of the suspected sample, dissolved in half a fluidounce of glacial acetic acid, will, if pure, remain colorless and clear, or but slightly cloudy, if from four to six drops of pure nitric acid be dropped into the solution. If the sample be pure gurjun balsam, the mixture will have a deep purple color; if a mixture of the two balsams, the depth of color will vary according to the amount of the adulterant, as small a proportion as 2 per cent. being discoverable. (See also *A. J. P.*, 1896, 143, and 1897, 394.)

Medical Properties and Uses. Copaiba is gently stimulant, diuretic, laxative, and in very large doses often actively purgative. It produces, when swallowed, a sense of heat in the throat and stomach, and extends an irritant action not only throughout the alimentary canal, but also to the urinary passages, and in fact, in a greater or less degree, to all the mucous membranes, for which it appears to have a strong affinity. The urine acquires a peculiar odor during its use, and its smell may be detected in the breath. It sometimes occasions an eruption upon the skin resembling that of measles, and attended with disagreeable itching and tingling, or even violent pemphigus. (*N. Y. Med. Journ.*, Jan. 1873, p. 416.) Nausea and vomiting, painful purgation, strangury and bloody urine, and a general state of fever are caused by excessive doses. As a remedy it has been found most efficient in diseases of the mucous membranes, particularly those of a chronic character. Thus, it is given with occasional advantage in *leucorrhœa*, *chronic cystitis*, *chronic dysentery*, *diarrhœa*, *hemorrhoids*, *chronic bronchitis*, and *psoriasis*. The complaint, however, in which it is most employed is *gonorrhœa*. It should not be administered in the first stages, when the inflammation is severe and acute, nor is it applicable to very chronic, indolent forms of the disorder, such as gleet. It was formerly much esteemed as a vulnerary, and as an application to *ulcers;* but it is now seldom used externally. Dr. Ruschenberger recommends it locally in *chilblains*. (*Med. Examiner*, i. 77.)

Both the volatile oil and the resin are eliminated by the kidneys in an altered condition: if to the urine of a person taking the drug nitric acid be added, a precipitate is thrown down, which may be mistaken for albumen. The volatile oil is more active than is the resin, which is not, however, inert. Dr. Wilks, of Guy's Hospital, London, speaks of the resin with great confidence as a hydragogue diuretic in obstinate *dropsy*, given in the dose of fifteen or twenty grains three times a day.

The dose of copaiba is from twenty drops to a fluidrachm (1·25–3·75 C.c.) three times a day, or a smaller quantity repeated more frequently. It may be given dropped on sugar, but in this form is often so exceedingly offensive as to render some concealment of its nauseous qualities necessary. A less disagreeable form is that of emulsion, prepared by rubbing the copaiba first with mucilage or the yolk of an egg, and sugar, and afterwards with some aromatic water, as that of mint or cinnamon. The *volatile oil*, which is official, may be given in the dose of ten or fifteen drops, in emulsion, or, as is almost universally preferred, in capsules.

CORIANDRUM. U. S. (Br.) Coriander.

(CŌ-RĮ-ĂN′DRŬM.)

"The fruit of Coriandrum sativum, Linné (nat. ord. Umbelliferæ)." *U. S.* "The dried ripe fruit of Coriandrum sativum." *Br.*

Coriandri Fructus, *Br.;* Coriander Fruit; Fructus Coriandri, *P. G.;* Coriandre, *Fr.;* Koriander, *G.;* Coriandro, *It.;* Cilantro, *Sp.*

Gen. Ch. Corolla radiate. *Petals* inflex-emarginate. *Universal involucre* one-leafed. *Partial involucres* halved. *Fruit* spherical. *Willd.*

Coriandrum sativum. Willd. *Sp. Plant.* i. 1448; Woodv. *Med. Bot.* p. 137, t. 53. This is an annual plant, with an erect, round, smooth, branching stem, rising about two feet, and furnished with compound leaves, of which the upper are thrice ternate, with linear pointed leaflets, the lower pinnate, with the pinnæ cut into irregular serrated lobes like those of parsley. The flowers are white or rose-colored, and in compound terminal umbels; the fruit globular, and composed of two concave hemispherical portions. *C. sativum* is a native of Italy, but at present grows wild in most parts of Europe, having become naturalized in consequence of its extended cultivation. The flowers appear in June, and the fruit ripens in August. It is a singular fact that all parts of the fresh plant are extremely fetid when bruised, while the fruit becomes fragrant by drying. This is the official portion. It is brought to us from Europe.

Transverse section magnified.

The fruit of the coriander is globular, about an eighth of an inch in diameter, obscurely ten-ribbed, with minute indications of secondary ribs in the furrows, of a grayish or brownish-yellow color, and separable into the two mericarps (half-fruits), which are only bound together by the membranous pericarp. Each half-fruit is provided with two oil-tubes on the conjoining face. The whole fruit has the persistent calyx at its base, and is sometimes surmounted by the adhering conical style. Coriander is thus described by the U. S. Pharm.: "Globular; about one-sixth of an inch (4 mm.) in diameter; crowned with the calyx-teeth and stylopod; brownish-yellow, with slight longitudinal ridges; the two mericarps cohering, enclosing a lenticular cavity, and each furnished on the face with two oil-tubes; odor and taste agreeably aromatic." *U. S.* The aromatic taste and smell depend on a *volatile oil*, which may be obtained separate by distillation. One pound of the seeds yields forty-two grains of the oil. (*Zeller.*) This is colorless or pale yellow, with an agreeable odor of coriander, a mild aromatic taste, and a sp. gr. varying from 0·87 to 0·88. Its main constituent, according to Semmler (*Ber. der Chem. Gesell.*, xxiv. 206), is what was first called *coriandrol*, but is now recognized as *linalool*, $C_{10}H_{18}O$, boiling between 194° and 198° C. Besides this, about 5 per cent. of *dextro-pinene* was isolated, boiling between 156° and 160° C. It is one of the most permanent of the volatile oils, resisting oxidation for a long time. The virtues of the fruit are imparted to alcohol by maceration, and less readily to water.

Medical Properties and Uses. Coriander is a rather feeble aromatic. It is almost exclusively employed in combination with other medicines, either to cover their taste, to render them acceptable to the stomach, or to correct their griping qualities. It was well known to the ancients. The dose is from a scruple to a drachm (1·3–3·9 Gm.).

CREOSOTUM. U. S., Br. Creosote.

(CRĒ-Ǫ-SŌ′TŬM.)

"A mixture of phenols, chiefly guaiacol and creosol, obtained during the distillation of wood-tar, preferably of that derived from the beech, Fagus sylvatica, Linné (nat. ord. Cupuliferæ)." *U. S.* "A mixture of guaiacol, creosol, and other phenols; obtained in the distillation of wood-tar." *Br.*

Creasotum, *Br.* (1885), Creasote; **Kreosotum,** *P. G.;* Créosote, *Fr.;* Kreosot, *G.**

This is a substance discovered in 1830 by Reichenbach in the products of the distillation of wood. This distillation of wood yields products very analogous to one fraction of the coal-tar obtained by the destructive distillation of bituminous coal. This fraction is the heavy oil of coal-tar, which comes over between 165° C. (329° F.) and 200° C. (392° F.): it is often called

* The official name of this compound was changed in the U. S. P. (1890) from "creasotum" to "creosotum." This alteration, in our opinion, is of doubtful utility: the original name is in accord with the etymological orthography.

"*coal-tar creosote*," and contains a group of phenols, including carbolic acid, or common *phenol*, C_6H_6O, boiling at 182° C. (359·6° F.), *cresylic acid*, or *cresol*, C_7H_8O, boiling at 198° C. (388·4° F.), and *xylenol*, or *dimethyl phenol*, $C_8H_{10}O$, boiling at 211° C. (411·8° F.). Wood-tar is a complex mixture of phenoloid bodies. These are chiefly the acid methylic ethers of catechol (or pyrocatechin) and its homologues. We may mention as the chief constituents—

A. Monohydric Phenols.		*B. Methylic Ethers of Dihydric Phenols.*	
Phenol, or carbolic acid	C_6H_5OH.	Guaiacol	$C_6H_4(OCH_3)OH$.
Paracresol	$C_6H_4(CH_3)OH$.	Creosol	$C_6H_3(CH_3)OCH_3.OH$.
Xylenol, or phlorol	$C_6H_3(CH_3)_2OH$.	Homocreosol	$C_6H_2(CH_3)_2OCH_3OH$.
		Cœrolignol	$C_6H_3(C_3H_7)OCH_3OH$.

C. Methylic Ethers of Trihydric Phenols.

Dimethyl pyrogallate	$C_6H_3(OCH_3)_2OH$.
Dimethyl methyl-pyrogallate	$C_6H_2(CH_3)(OCH_3)_2OH$.
Dimethyl propyl-pyrogallate (picamar)	$C_6H_2(C_3H_7)(OCH_3)_2OH$.
Methyl propyl-pyrogallate	$C_6H_2(C_3H_7)(OCH_3)(OH)_2$.

(*Allen's Com. Org. Analysis*, 2d ed., vol. ii. p. 565.)

Preparation. Creosote is obtained either from wood-tar or from crude pyroligneous acid. When wood-tar is used, it is distilled until it has attained the consistence of pitch. The distilled liquid divides itself into three layers, an aqueous between two oily layers. The inferior oily layer, which alone contains the creosote, is separated, and saturated with sodium carbonate to remove acetic acid. The liquid is allowed to rest, and the new oil which separates is decanted from it. This oil is distilled, and yields products lighter than water, and a liquid heavier. The latter alone is preserved, and, after having been agitated repeatedly with weak phosphoric acid to neutralize ammonia, is allowed to remain at rest for some time. It is next washed as long as acidity is removed, and then distilled with a fresh portion of weak phosphoric acid, care being taken to cohobate from time to time. The oily liquid thus rectified is colorless, and contains much creosote, but also a portion of light oil distillate. To separate the latter, the liquid is mixed with a solution of caustic soda of the density 1·12, which dissolves the creosote, but not the light oil. The oil, which floats from its levity, is then separated; and the alkaline solution of the creosote is exposed to the air, until it becomes brown in consequence of the decomposition of a foreign matter, and is then saturated with sulphuric acid. This sets free the creosote, which is decanted, and again distilled. The treatment by solution of soda, sulphuric acid, etc., is to be repeated until the creosote no longer becomes brown by exposure to the air, but only slightly reddish. It is then dissolved in a stronger solution of soda, and distilled again, and finally redistilled for the last time, rejecting the first portion which comes over, on account of its containing much water, collecting the next portion, and avoiding to push the distillation too far. The product collected in this distillation is creosote.

When creosote is extracted from pyroligneous acid, the first step is to dissolve sodium sulphate in it to saturation. The oil which separates and floats above is decanted, and, having been allowed to remain at rest for a few days, is saturated by potassium carbonate with the assistance of heat, and distilled with water. The oleaginous liquid obtained is of a pale yellow color, and is to be treated with phosphoric acid, etc., as above detailed, in relation to the treatment of the corresponding oil obtained from wood-tar.

Properties. Creosote, when pure, is a colorless oleaginous liquid, of the consistence of oil of almonds, slightly greasy to the touch, volatilizable by heat, and having a caustic, burning taste, and a penetrating, disagreeable odor, like that of smoked meat, and analogous to, yet different from, that of phenol. As met with in commerce, it has frequently a brownish tinge. It burns with a sooty flame. Applied in a concentrated state to the skin, it corrugates and then destroys the cuticle, causing a white spot. On paper it leaves a greasy stain, which disappears in a few hours, or in ten minutes if heated to 100° C. (212° F.). Its sp. gr. is 1·057 at 55° (Gorup-Besanez), 1·035–1·085 (*U. S.*), 1·079 (*Br.*). It boils between 200° and 220° C., and remains fluid at —27° C. (—17° F.). It is a non-conductor of electricity, and refracts light strongly. It is devoid of acid or alkaline reaction. Mixed with water, it forms two layers: one consisting of one part of creosote and about eighty of water, the other, of one part of water and ten of creosote. It dissolves a large proportion of iodine and phosphorus, and a considerable amount of sulphur, especially when assisted by heat. Allen states that in Rhenish creosote guaiacol predominates, while a sample of Morson's creosote from "Stockholm tar," examined by him, boiled at about 217° C., and consisted chiefly of creosol.

The Pharmacopœia describes creosote as "an almost colorless, yellowish or pinkish, highly refractive, oily liquid, having a penetrating, smoky odor, and a burning, caustic taste; usually becoming darker in tint on exposure to light. Specific gravity: not below 1·070 at 15° C. (59° F.). Soluble in about 150 parts of water at 15° C. (59° F.), but without forming a perfectly clear solution. With 120 parts of hot water it forms a clear liquid which on cooling becomes turbid from the separation of minute oily drops. The filtrate from this yields a reddish-brown precipitate with bromine test-solution (distinction from *carbolic acid*). Soluble, in all proportions, in absolute alcohol, ether, chloroform, benzin, carbon disulphide, acetic acid, and fixed and volatile oils. It begins to boil at about 205° C. (402·8° F.), and most of it distils over between 205° and 215° C. (401° and 419° F.). When it is cooled to —20° C. (—4° F.), it becomes gelatinous, but does not solidify (difference from *carbolic acid*). It is inflammable, burning with a luminous, smoky flame. Creosote is neutral, or only faintly acid to litmus paper. On mixing equal volumes of Creosote and collodion in a dry test-tube, no coagulum should form. If 1 volume of Creosote be mixed with 1 volume of glycerin, a nearly clear mixture will result from which the Creosote will separate on the addition of 1 or more volumes of water. On adding to 10 C.c. of a saturated, aqueous solution of Creosote 1 drop of ferric chloride test-solution, the liquid will acquire a violet-blue tint which rapidly changes to greenish and brown, with formation, usually, of a brown precipitate. (The preceding three tests show difference from and absence of notable quantities of *carbolic acid*.) On mixing 2 C.c. of Creosote with 8 C.c. of a 7·5-per-cent. solution of sodium hydrate, a clear, pale yellowish liquid results which becomes turbid when diluted with water, but clears up after 50 C.c. have been added (absence of *neutral oils*). If 1 C.c. of Creosote be mixed with a warm, 20-per-cent. solution of potassium hydrate in absolute alcohol, a solid crystalline mass will form upon cooling. If 1 C.c. of Creosote be shaken with 2 C.c. of benzin and 2 C.c. of freshly prepared barium hydrate test-solution, upon separating, the benzin should not be blue or muddy, and the aqueous layer should not have a red tint (absence of *cœruligiol* and some *other high-boiling constituents of wood-tar*)." *U. S.* The British Pharmacopœia describes Creosote as follows: "A colorless or yellowish highly refractive liquid, having a strong empyreumatic odor and acrid taste; neutral or only faintly acid to litmus. It is dissolved by about 150 parts of water at ordinary temperatures, and is more soluble in hot water. It is freely soluble in *alcohol* (90 per cent.), *ether*, *chloroform*, *glycerin*, and *glacial acetic acid*. Specific gravity, not below 1·079. It distils between 392° F. (200° C.) and 428° F. (220° C.). A 1 per cent. solution in *alcohol* (90 per cent.), or a half per cent. solution in *water*, with a drop of the *test-solution of ferric chloride*, yields a green coloration, rapidly changing to a reddish brown. It rotates the plane of a ray of polarized light to the left. Dropped on white filtering paper and exposed to a temperature of 212° F. (100° C.), it leaves no translucent stain (absence of less volatile liquids). It is miscible with an equal volume of *collodion* without gelatinization; and, when shaken with 5 times its bulk of *solution of ammonia*, its volume should not be diminished materially (distinction from phenol)."

Creosote instantly dissolves ammonia, and retains it with great force. Strong nitric and sulphuric acids decompose it, the former giving rise to reddish vapors, the latter to a red color, which becomes black on the addition of more of the acid. Dilute nitric acid converts it into a brown resin, which, treated with ammonia, and then dissolved in boiling alcohol, gives, by evaporation, certain salts of ammonia, two of which contain new acids, discovered by Laurent. Hydrochloric acid produces no change in it. Mr. Morson, of London, gives a test based on the solvent power of glycerin over carbolic acid, which is dissolved by it in all proportions, while pure creosote is insoluble or nearly so; and, consequently, if any liquid assumed to be creosote dissolves largely in glycerin, it probably consists in the whole, or in large part, of carbolic acid. Subsequent experiments appear to show that this test succeeds best with Morson's creosote; and beech-wood creosote, although pure, sometimes mixes with glycerin without turbidity. Hager has modified Morson's test by using a mixture of 3 parts absolute glycerin and 1 part water. With this fairly good results are obtained, according to Allen. A still better test, according to Mr. John A. Clark, is an alcoholic solution of iron perchloride (*Tinct. Ferri Perchlor.*, Br.), which with an alcoholic solution of creosote produces a deep greenish-blue color, but with carbolic acid a light brown. (*A. J. P.*, June, 1873, 269.) Creosote dissolves a large number of metallic salts, and reduces some of them to the metallic state; as, for example, silver nitrate and acetate. *Froehde's reagent* (a solution of 1 part of molybdic acid in 100 parts of sulphuric acid) is recommended by E. W. Davy as a distinguishing test for carbolic acid. (*P. J. Tr.*, 1878, 1022.) A drop or two of the doubt-

ful liquid is to be agitated with two fluidrachms of distilled water, the whole filtered, and a drop or two of the test-solution added. Pure creosote gives a brown or reddish-brown reaction on standing or slight warming, passing to a light yellowish brown; with carbolic acid, the brown passing to a maroon soon develops a more or less intense purple. Of all the properties of creosote, the most remarkable is its power of preserving meat. It is this property which has suggested its name, derived from *κρεάς, flesh,* and *σώζω, I preserve.*

Impurities and Adulterations. Creosote is apt to contain eupion, and is sometimes adulterated with rectified oil of tar and the fixed and volatile oils. All these substances are detected by strong acetic acid, which dissolves the creosote, and leaves them behind, floating above the creosote solution. Creosote from beech-wood tar, however, is only partially dissolved by hot acetic acid of ordinary strength. Fixed oils are also discovered by a stain on paper not discharged by heat. Any trace of the matter which produces the brownish tinge is detected by the liquid becoming discolored by exposure to sunshine. Commercial creosote almost always contains carbolic and cresylic acids, from coal-tar; and, indeed, much of what is sold for creosote is nothing more than impure carbolic acid. (See *Acidum Carbolicum.*) It has been already stated that this acid strongly resembles creosote; and this resemblance probably extends also to their therapeutical effects: so that the substitution is less to be regretted than might otherwise be the case. But, as the effects of the two on the system may not be identical, it is highly desirable to be able to distinguish between them. Tests for this purpose have been given above, and, with those quoted from the Pharmacopœia, are sufficient for the purpose.

Medical Properties, etc. The constitution of even genuine beech-wood creosote varies very greatly in the proportion of guaiacol and creosol and in the amount of monophenols, and it would seem impossible to get under the name of creosote a fixed medicament. Nevertheless, for practical therapeutic purposes creosote is sufficiently constant in its composition, the physiological and therapeutic action of its various constituents being apparently so closely allied as to make variability in the proportion of these constituents of little importance; indeed, our knowledge of the physiological effects of creosote is very imperfect. It rivals carbolic acid in its antiseptic power. It is, when applied locally, a paralyzant to the nerves, and probably to all higher tissues; and it has been generally believed to be almost identical in the range and powers of its activity with carbolic acid. If it be true, however, as stated in *La Semaine Méd.*, July, 1891, that Prof. Bouchard has administered it in doses of two and a half drachms without evil result, it cannot be physiologically equivalent to carbolic acid. The correctness of this view is further indicated by the rarity of cases of creosote poisoning in the records of medicine. Dr. Freudenthal (*N. Y. Med. Rec.*, April, 1892) reports the case of a woman who took 600 drops of creosote in a very short time, the ingestion being followed almost immediately by unconsciousness, with intense trismus, contracted immobile pupils, and general cyanosis, but in which recovery was made practically without the administration of remedies. He further states that subsequently this same patient, by increasing the dose of creosote, was able to take 500 drops daily without ill effect. Creosote was originally administered in *phthisis* with the idea of destroying the tubercle bacillus. There is, however, no reason for believing that it directly affects the growth of this organism, although it undoubtedly is a very effectual remedy in the disease. Its value is almost in direct proportion to the amount of expectoration,—*i.e.*, to the activity of the catarrhal processes. It acts by influencing the pulmonic catarrh, which, although a secondary result of the bacillus, favors greatly their growth. It is of at least equal service in cases of chronic *non-tubercular inflammation* of the bronchial tubes, and even of the lung structure itself when the disease is of a catarrhal type. To be effective it must be given in as large doses as the stomach can bear, and its use must be continually kept up for weeks and even months. It may be given in cod-liver oil or emulsion, but is usually best tolerated in capsules (three to five minims each). Two of these may be administered at first four times a day, the dose being gradually increased until from thirty to forty minims a day are taken, or some evidences of disagreement with the digestion appear. The remedy should be taken after meals, or the ingestion should be immediately preceded by a glass of milk. Creosote has also been used hypodermically in phthisis. Thus, Perom employed a 10 per cent. solution given in oil of sweet almonds, two injections of eighty minims each being given daily. Dor administered, by intra-tracheal injections, a 5 per cent. solution in recently boiled olive oil, holding that the drug reached the pulmonic alveoli and attacked the disease locally. On account of its local action as a powerful paralyzant of nerve-tissue, creosote is frequently employed with great advantage in cases of *nausea*, *vomiting*, or *diarrhœa* dependent upon excessive irritability, without acute inflammation, of the gastric or intestinal mucous membrane; it has

also been successfully used in the *vomiting of pregnancy* or of *hysteria*, in *cholera morbus*, *cholera infantum*, *lienteric diarrhœa*, *typhoid fever*, and even in *dysentery*. When in these cases there is a tendency to fermentation of the contents of the stomach or bowels, creosote is especially valuable, and may often be combined advantageously with an alkali or chalk. Externally, creosote has been employed for exactly the same diseases as has carbolic acid. Indeed, the latter remedy, on account of its greater cheapness, has almost entirely supplanted creosote. The skin diseases to the treatment of which creosote has been supposed to be best suited are those of a scaly character. In *burns* its efficacy has been insisted on, especially in those attended with excessive suppuration and fungous granulations. In *chilblains* also it is stated to be a useful application. Mixed with four parts of lard, it is said to have proved very serviceable in *erysipelas*. When applied to wounds it acts as a hæmostatic, stopping the capillary hemorrhage, but possesses no power to arrest the bleeding from large vessels. Accordingly, creosote water has been applied locally in *menorrhagia*, and to arrest *uterine hemorrhage* and the bleeding from leech-bites. The ulcers in the treatment of which it has been found most useful are those of an indolent and gangrenous character, in which its several properties of escharotic, stimulant, and antiseptic are usefully brought into play. In all these cases, should the remedy cause irritation, it must be suspended, or alternated with emollient and soothing applications. Injected into fistulous ulcers, it proves a useful resource, by exciting the callous surfaces and disposing them to unite. Wherever there are foul ulcers, gangrenous surfaces, or inflamed serous, mucous, or glandular tissues giving rise to fetid discharges, creosote may be substituted for carbolic acid; as examples may be mentioned fetid *leucorrhœa*, puerperal *metritis*, fetid *otorrhœa*, putrid or *diphtheritic sore throat*, chronic *empyema*. The strength of the application may vary from that of pure creosote to a single drop to the fluidounce of water, according to the delicacy of the part and the severity of the disease. On account of its local anæsthetic and antiseptic influence, it is much employed by dentists for the obtunding of sensitive dentine and as an ingredient of pastes for the destruction of nerves. One or two drops of the pure substance must be carefully introduced into the hollow of the tooth on a little cotton, avoiding contact with the tongue or cheek. To render it effectual, the hollow of the tooth must be well cleansed before it is applied. A mixture of 15 parts of creosote and 10 of collodion is said to have a jelly-like consistence, and to be usefully applied to carious teeth, which it protects from the air; but, as pure creosote does not coagulate collodion, this remark applies properly to the impure carbolic acid before stated to be commonly sold under the same name.

In an overdose creosote acts as a poison, producing giddiness, obscurity of vision, depressed action of the heart, convulsions, and coma. Prof. Hobart A. Hare has found that sulphuric acid and the soluble sulphates are antidotal to creosote as they are to carbolic acid. The medical treatment consists in the evacuation of the poison and the administration of ammonia and other stimulants.

Under the name of Vapor Creasoti (*Inhalation of Creasote*), the British Pharmacopœia (1885) formerly directed a preparation consisting of 12 minims of creasote and 8 fluidounces of boiling water, which were directed to be mixed in an inhaling apparatus, so arranged that the air should be made to pass through the solution, and then inhaled. It may be used in chronic inflammation of the air-passages.

CRETA PRÆPARATA. U. S., Br. Prepared Chalk.

"Native calcium carbonate, freed from most of its impurities by elutriation." *Br.*

Craie préparée, *Fr.;* **Präparirte Kreide,** *G.*

Calcium carbonate, in the extended meaning of the term, is the most abundant of simple minerals, constituting, according to its state of aggregation and other peculiarities, the different varieties of calcareous spar, common and shell limestone, marble, marl, and chalk. It occurs also in the animal kingdom, forming the principal part of shells, and a small proportion of the bones of the higher orders of animals. It is present in small quantity in most natural waters, being held in solution by the carbonic acid which they contain. In the waters of limestone districts it is a very common impregnation, and causes purging in those not accustomed to its use. In all such cases, boiling the water, by expelling the carbonic acid, causes the carbonate to be deposited. It has been shown, however, that calcium carbonate is itself in a slight degree soluble in water; so that a small proportion remains in limestone water which has been long exposed to boiling. That the carbonate is not held in solution by free carbonic acid is shown by the fact that lime water causes no precipitation. (*Journ. de Pharm. et de Chim.*, 4e

sér., iii. 147.) Besides being official in the state of chalk, calcium carbonate is also ordered as it exists in marble and oyster-shell, and as obtained by precipitation. Chalk occurs abundantly in the south of England and the north of France. It exists massive in beds, and very frequently contains nodules of flint, and fossil remains of land and marine animals. According to F. V. Hayden, chalk-beds identical with those of Europe extend for 400 miles along the Missouri River in Dakota. Chalk is an insipid, inodorous, insoluble, opaque, soft solid, generally white, but grayish white when impure. It is rough to the touch, easily pulverized, and breaks with an earthy fracture. It soils the fingers, yields a white trace when drawn across an unyielding surface, and when applied to the tongue adheres slightly. Its sp. gr. varies from 2·3 to 2·6. It is never a perfectly pure calcium carbonate, but contains, besides gritty silicious particles, small portions of alumina and ferric oxide. If pure, it is entirely soluble in hydrochloric acid; but usually a little silica is left. If this solution be not precipitated by ammonia, it is free from alumina and iron. Chalk, on account of the gritty particles which it contains, is unfit for medicinal use until it has been reduced to a very fine powder. The mineral, previously pulverized, should be rubbed with a little water upon a porphyry slab, by means of a muller of the same material. Having been thus very minutely divided, it is agitated with water, which upon standing a short time deposits the coarser particles, and, being then poured off, slowly lets fall the remainder in an impalpable state. The former part of the process is called *levigation*, the latter *elutriation*. The soft mass which remains after the decanting of the clear liquor is made to fall upon an absorbent surface in small portions, which when dried have a conical shape.* Practically, prepared chalk is generally made on the large scale from *whiting* by the manufacturer. (See *P. J. Tr.*, vii. 146.)†

"A white, amorphous powder, often moulded into conical drops, odorless and tasteless; permanent in the air. Almost insoluble in water; insoluble in alcohol. Soluble in diluted acetic, hydrochloric, or nitric acid with copious effervescence, but without leaving more than a trifling residue. When heated to redness Prepared Chalk loses carbon dioxide and is converted into lime. The solution in diluted acetic acid yields, with ammonium oxalate test-solution, a white precipitate insoluble in acetic, but soluble in hydrochloric acid. If from the solution in diluted acetic acid the calcium be completely removed by precipitation with ammonium oxalate test-solution in slight excess, the filtrate should not be rendered very turbid upon addition of sodium phosphate test-solution and a little ammonia water (limit of *magnesium*). Another portion of the solution in acetic acid should not assume more than a slight bluish tint upon addition of potassium ferrocyanide test-solution (limit of *iron*). Another portion of the same solution should not be rendered turbid by the addition of barium chloride test-solution (absence of *sulphate*). In another portion of the solution no precipitate should occur upon the addition of potassium dichromate test-solution (absence of *barium*)." *U. S.*

Medical Properties and Uses. This is the only form in which chalk is used in medicine. It is an excellent antacid; and, as the salts which it forms in the stomach and bowels, if not astringent, are at least not purgative, it is admirably adapted to *diarrhœa* accompanied with acidity. It is also sometimes used in acidity of stomach attending *dyspepsia* and *gout*, when a laxative effect is to be avoided; and it is one of the best antidotes for oxalic acid. It has been employed as an application to *burns* and *ulcers*, which it moderately stimulates, while it absorbs the ichorous discharge and thus prevents it from irritating the diseased surface or the sound skin. It is given internally in the form of powder, or suspended in water by the intervention of gum arabic and sugar. (See *Mistura Cretæ*.) It is better fitted for the chalk mixture than the precipitated calcium carbonate, in consequence of its more impalpable character and greater powers of adhesion. Dose, from ten to forty grains (0·65–2·6 Gm.).

CROCUS. U. S., Br. Saffron.

(CRŌ'CŬS.)

"The stigmas of Crocus sativus, Linné (nat. ord. Irideæ)." *U. S.* "The dried stigmas and tops of the styles of Crocus sativus, Linn." *Br.*

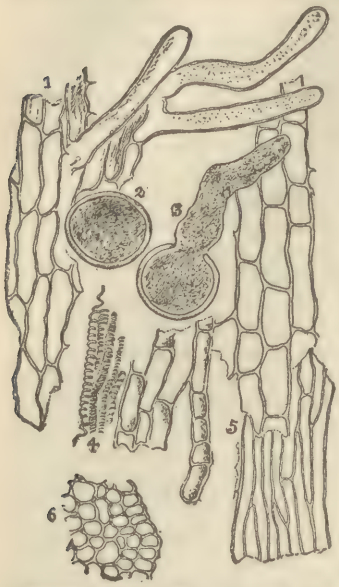
* "Take of Chalk *a convenient quantity*. Add a little water to the Chalk, and rub it into fine powder. Throw this into a large vessel nearly full of water, stir briskly, and, after a short interval, decant the supernatant liquor, while yet turbid, into another vessel. Treat the coarser particles of the Chalk, remaining in the first vessel, in a similar manner, and add the turbid liquid to that previously decanted. Lastly, set the liquor by, that the powder may subside, and, having poured off the water, dry the powder." *U. S.* 1870.

† Mr. F. Harris Alcock found some very handsome specimens of "prepared chalk" in the English market to contain 67·016 per cent. of calcium sulphate. (*P. J. Tr.*, 1883, p. 1015.)

Crocus sativus. Willd. *Sp. Plant.* i. 194; Woodv. *Med. Bot.* p. 763, t. 259. The common cultivated saffron is a perennial plant, with a rounded and depressed bulb or cormus, from which the flower rises a little above the ground, upon a long, slender, white, and succulent tube. The flower is large, of a beautiful lilac or bluish-purple color, and appears in September or October. The leaves are radical, linear, slightly revolute, dark green upon their upper surface, with a white longitudinal furrow in the centre, paler underneath, with a prominent flattened midrib, and enclosed at their base, together with the tube of the corolla, in a membranous sheath, from which they emerge soon after the appearance of the flower. The style hangs out on one side between the two segments of the corolla, and terminates in three long convoluted stigmas, which are of a rich orange color, highly odorous, rolled in at the edges, and notched at the summit. The stigmas of the *Crocus orientalis* are used in the East.

C. sativus, or *autumnal crocus*, is believed to be a native of Greece and Asia Minor, where it has been cultivated from the earliest ages. It is, however, unknown in a wild state, and, as the French plant does not produce seed, Chappellier asserts that it is a hybrid. (*Bull. Soc. Bot. de France*, xx.) More recently, however, Chappellier has found that the ordinary crocus, as grown in France, is readily fertilized by the Grecian variety, and it is most probable that the species is a distinct one. There are three main varieties of it, the French, the Grecian, and the Chinese. The first of these is superior in color and flavor, the second in the amount of yield, whilst the third is said to unite these qualities. Saffron is also cultivated for medicinal use in Sicily, Spain, France, England, and other temperate countries of Europe. Large quantities of saffron are raised in Egypt, Persia, and Cashmere, whence it is sent to India. Much of the drug reaches the market of Constantinople from the neighborhood of Tiflis and the Caucasus. We cultivate the plant in this country chiefly as a garden flower, although some of the drug of very fine quality has been produced in Pennsylvania. It is liable to two diseases, which interfere with its culture,—one dependent on a parasitic fungus which attaches itself to the bulb, the other called by the cultivators in France *tacon*, by which the bulb is converted into a blackish powder. (*Journ. de Pharm.*, xviii. 41.)

In England the flowers appear in October, and the leaves continue green through the winter; but the plant does not ripen its seed, and is propagated by offsets from the bulb. These are planted in grounds prepared for the purpose, and are arranged either in rows or in small patches at certain distances. The flowers are gathered soon after they show themselves, as the period of flowering is very short. The stigmas, or summits of the pistils, together with a portion of the style, are separated from the remainder of the flower, and carefully dried by artificial heat, or in the sun. During this process they are sometimes made to assume the form of a cake by pressure; but the finest saffron is that which has been dried loosely. The two forms are distinguished by the names of *cake-saffron* and *hay-saffron*. Five pounds of the fresh stigmas are said to yield one pound of the dried. The English saffron, formerly most highly esteemed in this country, has disappeared from our market. What may be sold under the name is probably derived from other sources. Much of the drug is imported from Gibraltar, packed in canisters. Parcels of it are also brought from Trieste and other ports of the Mediterranean. The Spanish saffron is generally considered the best in the United States, although most European writers in Materia Medica give the preference to the French saffron. Genuine *cake-saffron* is at present seldom found in commerce. The better grades of Spanish saffron are known as *Valencia* saffron, whilst *Alicante* saffron is said by Prof. Maisch to contain scarcely more than 50 per cent. of genuine saffron. According to Landerer, the stigmas of several other species besides those of *C. sativus* are gathered and sold as saffron in Greece and Turkey.*



* At the International Exhibition in London in the year 1862, Dr. Geo. B. Wood noticed a specimen of saffron from the island of Ceylon, closely resembling that of the *Crocus sativus*. It consisted of the stigmas of the *Crocus orientalis*. According to Mr. Charles A. Heinitsh, until within a few years saffron was cultivated to a considerable extent in Lancaster County, Pa. The plant requires a rich soil, which should be deeply dug and heavily manured. The bulbs are planted in August, eight inches apart, and the growing plant should be kept free from weeds. The flowering period begins about the middle of September, and continues till the beginning of October. The flowers are picked early in the morning, and the stigmas separated and dried in the shade. This is done every day during the period of flowering. He thinks the cultivation can be profitably conducted. A plot of 72 square feet will produce 9000 stigmas, weighing 420 grains, or from 33 to 36 pounds to the acre. (*A. J. P.*, 1867, p. 38.) In the Apennines the bulbs, which have been left in the ground during the winter without protection, are removed in August, are planted again in September in rows, and four weeks later the collection of the flowers is begun. (See *Arch. d. Pharm.*, Aug. 1885.) For an account of the cultivation in England, see *P. J. Tr.*, June, 1887. M. Monthus, an experienced cultivator in France, prefers a dry calcareous soil: plants the bulbs 3 or 4 inches deep; after the harvest in October manures the ground; and renews the planting every three years. He thus prevents the diseases peculiar to the plant. M. Monthus recommends the *petals* of the flower as applicable to the same purposes as the

Properties. Saffron has a peculiar, sweetish, aromatic odor, a warm, pungent, bitter taste, and a rich deep orange color, which it imparts to the saliva when chewed. The stigmas of which it consists are an inch or more in length, expanded and notched at the upper extremity, and narrowing towards the lower, where they terminate in a slender, capillary, yellowish portion, forming a part of the style. They are thus officially described: "Separate stigmas, or three, attached to the top of the style, about 3 Cm. long, flattish-tubular, almost thread-like, broader and notched above; orange-brown; odor strong, peculiar, aromatic; taste bitterish and aromatic. Saffron should not include the yellow styles. When pressed between filtering paper, it should not leave an oily stain. When chewed it tinges the saliva deep orange-yellow. When soaked in water, it should not deposit any pulverulent, mineral matter, nor show the presence of organic substances differing in shape from that described. On agitating 1 part of Saffron with 100,000 parts of water, the liquid will acquire a distinctly yellow color. No color is imparted to benzin agitated with Saffron (absence of *picric acid* and some *other coal-tar colors*). On drying Saffron at 100° C. (212° F.), it should not lose more than 14 per cent. of its weight (absence of *added water*). When thus dried, and ignited with free access of air, 100 parts of the dry Saffron should not leave more than 7·5 per cent. of ash (absence of *foreign inorganic substances*)." *U. S.* "Incinerated with free access of air, dried Saffron does not deflagrate (absence of nitrates), and yields about 7 per cent. of ash. It should not lose more than 12·5 per cent. of moisture when dried at 212° F. (100° C.)." *Br.* Analyzed by Vogel and Bouillon-Lagrange, saffron afforded 65 per cent. of a peculiar extractive matter, and 7·5 of an odorous volatile oil, together with wax, gum, albumen, saline matter, water, and lignin. The extractive was named *polychroïte*, from the changes of color which it undergoes by the action of reagents. Weiss (Wiggers and Husemann, *Jahresbericht*, 1868, 35) considered polychroïte to be a glucoside, but later researches have shown that it is a mixture of the glucoside crocin, sugar, and essential oil. (Planchon, *Drogues Simples*, vol. i. 210.) Kayser obtained (*Ber. der Chem. Ges.*, 1884, 2228) pure *crocin*, having the formula $C_{44}H_{70}O_{28}$, as a yellow powder, easily soluble in water and dilute alcohol, slightly soluble only in absolute alcohol, and giving with concentrated sulphuric acid a deep blue color, which turns violet, then cherry-red, and finally brown. It is easily decomposed by lime or baryta water into *crocetin* and a right-rotating sugar which Kayser calls *crocose*. The crocetin is a red powder, not soluble in water, but easily soluble in alcohol and ether. Its solution in alkalies shows an orange-yellow color, from which solution acids separate it again in orange-colored flocks. Its formula is $C_{34}H_{46}O_9$. Kayser also found a colorless bitter principle, to which he gave the name *picro-crocin* or *saffron bitter*, and the formula $C_{38}H_{66}O_{17}$, which is also of glucoside character. It is to the essential oil, which, according to M. Henry, is present to the amount of 10 per cent., that the medicine owes its activity. It may be partially separated by distillation. It has the formula $C_{10}H_{14}O$, boils at 208°–210° C. (406·4°–410° F.), is yellow, of a hot, acrid, bitterish taste, and heavier than water, in which it is slightly soluble.

Adulterations. The high price of this medicine gives rise to frequent adulterations. Water is said to be very often added in order to increase its weight. Oil or glycerin is also added for the same purpose, or to improve the appearance. In some specimens the dyed corolla of the crocus with the attached stamens is abundant. Sometimes the flowers of other plants, particularly *Carthamus tinctorius*, or safflower, *Calendula officinalis*, or official marigold, and *arnica*, are fraudulently mixed with the genuine stigmas. They may be known by their shape, which is rendered obvious by throwing a portion of the suspected mass into hot water, which causes them to expand. (See *Carthamus*.) A specimen of this adulteration has been introduced into the American market, by the name of *African saffron*. (Maisch, *A. J. P.*, March, 1872, p. 110.) Other adulterations are the fibres of dried beef, the stamens of the crocus, distinguishable by their yellow color, the stigmas previously exhausted in the preparation of the infusion or tincture, and various mineral substances, easily detected upon close examination. The

stigmas, having found them to be possessed of aromatic properties. They demand no peculiar caution in drying; but to preserve them it is necessary to exclude light and moisture. Acids redden them with extreme facility, and alkalies turn them green. He therefore recommends a tincture to be made from them, as a substitute for syrup of violets. He prepares the tincture by macerating 10 parts of the dried flowers in 100 parts of alcohol of 40°, for 48 hours. A longer maceration would destroy the color. Paper may be stained with the tincture, and kept green or red, the former for acids, the latter for alkalies. (*Journ. de Pharm.*, Juillet, 1867, 54.) According to Heim, *Crocosma aurea*, Pl., which is cultivated in Southern Africa as a dye-stuff, affords an excellent substitute for saffron, the dried petals giving, when diluted with water, a brilliant yellow solution. The yellow coloring matter is more soluble in dilute alcohol and in alkaline solutions than in water, but is insoluble in absolute alcohol and in benzol. The partly dry aqueous extract gives with sulphuric acid a blue coloration, passing to violet, similar to that obtained from saffron.

flowers of a Brazilian plant named *Fuminella* have, according to M. J. L. Soubeiran, been employed for the adulteration of saffron. They may be detected by shaking, gently but repeatedly, a large pinch of the suspected saffron over a piece of paper. The flowers of Fuminella, being smaller and heavier, separate and fall, and may be seen to consist of very short fragments, with a color like that of saffron, but a rusty tint which the latter does not possess. (See *Pharm. Review*, 1898, 258.) J. Müller recommends concentrated sulphuric acid as the most certain test of saffron. It instantly changes the color of pure saffron to indigo blue. (*Chem. Gaz.*, May, 1845.) An adulteration which has been largely practised appears to consist of yellow-colored chalk or barium sulphate, made into a thin paste probably with honey, and attached to the stigmas, sometimes isolated, sometimes in groups of five or six, enveloping them almost completely. If this saffron be kept in a dry place, and often handled, the paste becomes partly broken up, and the colored powder spreads itself in the mass and the envelope. The chalk can at once be detected by shaking the suspected saffron with water, and treating the precipitated powder with hydrochloric acid, when effervescence will occur. A less than the ordinary brightness of color in the saffron should lead to suspicion of this adulteration. Much can be told as to the purity of saffron by agitating the suspected flowers in distilled water; if the drug be pure the liquid will remain clear, slowly assuming a fine pure yellow tint; the saffron also will retain its red color for hours. Another excellent plan is to scatter a pinch of the flowers upon the surface of warm water, when the stigmas should spread out and display their proper form. Minute fragments of red saunders, which are often added to saffron, may be separated by agitating with water. For an elaborate discussion of adulteration, see *A. J. P.*, 1885, 487.* In various European markets there has been offered a saffron largely adulterated with borates, chlorides, and other salts of sodium and potassium, and yet retaining the physical properties of saffron of high character. These and other adulterations with inorganic salts can be detected by the amount of ash left on burning, genuine saffron leaving from five to seven per cent. This saffron also yielded immediately to water an orange-yellow color. Further, some of it at least was hygroscopic, so that when rubbed up between the fingers into a ball it retained that form instead of being elastic as is true saffron.

Fragment of coarsely powdered Crocus. 1, epidermis, showing hair; 2, pollen cell; 3, pollen cell commencing to grow; 4, bundles of wood vessels; 5, parenchymatous tissue with epidermis; 6, transverse section, showing parenchyma and epithelium.

Attention has been called to a product of the Cape of Good Hope, named *Cape saffron*, which has a remarkable resemblance to genuine saffron, having a similar odor, and yielding a similar color to water, though the flowers themselves are differently colored. It is the flower of a small plant very abundant at the Cape, belonging to the family of *Scrophulariaceæ*, and is said by Dr. Pappé, of Cape Town, to possess medical virtues closely resembling those of true

* B. S. Procter has proposed a color test which would seem to be very efficient. One grain of saffron is to be agitated with two drachms of ether, which should become fairly yellow (any over-coloring of the ether indicates aniline or other dye); ether decanted; saffron dried, then agitated with two drachms of rectified spirit, and heated short of ebullition, for about one hour; next dried with two drachms of water in the same manner; this alternate use of spirit and water is to be continued until the solvent ceases to extract color and the fibres are nearly white; the total liquors being made up to exactly two fluidounces should have a color closely resembling that of fourteen grains of potassium bichromate in two ounces of water. In comparison, the best results are obtained by taking eight minims of the standard liquor and diluting it with an ounce of water, half filling a test-tube about half an inch in diameter with this diluted standard, then adding to an ounce of water eight minims of the liquor obtained from the sample under examination, and, having half filled a similar test-tube with this, holding the two tubes side by side against a sheet of white paper. E. Vinassa recommends that saffron should always be steeped in petroleum before examination under the microscope, and the particles should then all present equality in coloration. Immersion in chloral hydrate and subsequent boiling with water enable the operator easily to detect admixtures of sandal or campeche wood and of safflower. Attention should also be paid to the pollen-grains, hairs, and crystals present. Chemical examination shows that the amount of water should not exceed 16 per cent. and the ash 8 per cent. in a good sample, whilst the tinctorial power may be estimated by comparison with potassium bichromate solution. The capillary behavior of an aqueous solution of saffron is also very interesting, and is distinguished from that of any other natural or artificial coloring matter in that distinct zones of color are produced in strips of filtering paper dipped in the solution, the uppermost zone being terminated by a sharply defined light yellow line. (*Bull. Pharm.*, Nov. 1892.)

saffron. The flowers have been used successfully in the convulsions of children. (*P. J. Tr.*, vi. 462, 1865.)

Choice of Saffron. Saffron should not be very moist, nor very dry, nor easily pulverized; nor should it emit an offensive smell when thrown upon live coals. The freshest is the best, and that which is less than a year old should, if possible, be selected. It should possess in a high degree the characteristic properties of color, taste, and smell. When agitated with water it should color it bright yellow, and it should not effervesce in the presence of a dilute acid. If it does not color the fingers when rubbed between them, or if it has an oily feel, or a musty flavor, or a black, yellow, or whitish color, it should be rejected. In the purchase of this medicine in cakes, those should be selected which are close, tough, and firm in tearing; and care should be taken to avoid *cakes of safflower.*

As its activity depends, partly at least, on a volatile ingredient, saffron should be kept in well-stopped vessels. Some recommend that it should be enclosed in a bladder and introduced into a tin case.

Medical Properties and Uses. Saffron was extensively used by the ancients and by mediæval physicians, as a highly stimulant antispasmodic and even narcotic emmenagogue, and is still employed to some extent upon the Continent; but in Great Britain and the United States it has fallen into well-deserved and almost complete desuetude. In domestic practice saffron tea is occasionally used in *exanthematous* diseases, to promote the eruption. At present it is chiefly used to impart color and flavor. The dose is from ten to thirty grains (0·65–1·95 Gm.).*

CUBEBA. U. S. (Br.) Cubebs. [Cubeb.]

(CŪ-BĒ'BA.)

"The unripe fruit of Piper Cubeba, Linné filius (nat. ord. Piperaceæ)." *U. S.* "The dried full-grown unripe fruits of Piper Cubeba, Linn. fil." *Br.*†

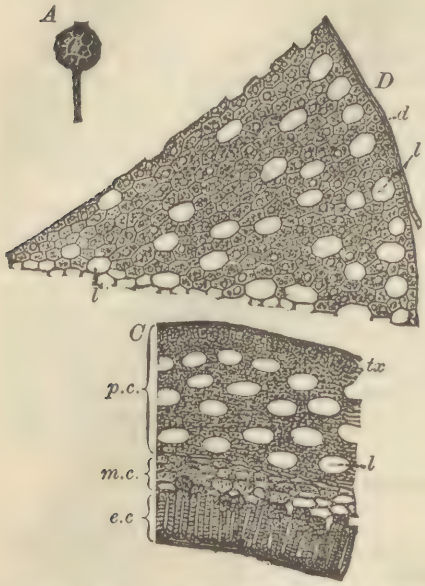
Cubebæ Fructus, *Br.;* Cubebs, Cubebæ, *P. G.;* Fructus (s. Baccæ) Cubebæ, Piper Caudatum; Cubèbe, Cubèbe poivre à Queue, *Fr.;* Kubeben, *G.;* Cubebe, *It.;* Cubebas, *Sp.;* Kebabeh, *Ar.*

* *Syrupus Croci.* A *Syrup of Saffron* is sometimes called for, and would seem to be an appropriate preparation. The following formula is recommended by Mr. Geo. W. Kennedy, of Pottsville, as producing excellent results. Take of saffron ℥ss, glycerin, ℥ij, water, ℥vi. Macerate for a week, filter into a pint bottle, and add sufficient water through the filter to make ℥viij; then add 14 avoird. oz. of sugar, and dissolve without heat, frequently shaking. (*A. J. P.*, Feb. 1871, 54.)

† The fruit of the *Piper afzelii* of Lindley, *Cubeba clusii* of Miquel, figured in the *P. J. Tr.* (xiv. 201), is known in commerce as *African cubebs, Ashantee pepper, Guinea pepper,* or *African black pepper.* It was formerly taken to Europe in considerable quantities by the Portuguese, but has been superseded by the more agreeable products of the East Indies. The fruit is one-third smaller than the official cubebs, is more compact, and has a taste more analogous to that of ordinary black pepper. Dr. Stenhouse has also shown that it is chemically more analogous to black pepper than to cubebs, as it contains piperin and not cubebin. (*Ibid.*, xiv. 364.) An alleged *African cubebs* which has been sent to London from Cape Coast Castle, in Africa, is the fruit of a plant belonging to the *Xanthoxylaceæ,* probably either a *Toddalia* or a *Vepris.* According to Prof. Archer, it is simply aromatic and stimulant, without any of the special virtues of cubebs. (*P. J. Tr.*, March, 1865, 463.)

Our knowledge of the false cubebs of commerce up to 1894 was epitomized in the last edition of the U. S. D., p. 457. To this account the reader is referred for historical details. In 1894 the subject was much clarified by A. De Wevre, a long abstract of whose memoir may be found in the *P. J. Tr.*, xxv., 1894. It appears that the natives of Java recognize three varieties of the cubeb plant under the respective names of *Rinoe katoentjar, Rinoe badak,* and *Rinoe tjaroelock.* Of these the first is true cubeb.

Rinoe badak yields a fruit strongly resembling the genuine cubeb, but having from eight to nine or even twelve rows of cells in the mesocarp, and yielding, when crushed with sulphuric acid, a yellow-brown or orange tone instead of the carmine-red color given by the true cubeb.



Rinoe tjaroelock is believed by De Wevre to be the *Piper crassipes* of Kirkby, and to be simply a variety of *Piper cubeba,* so that its fruit must be considered to be a true cubeb, though it differs from the official drug in having its pedicel about twice as long as the fruit and flattened throughout, and in having an odor of mace and a more bitter and less burning taste than true cubebs, and yielding, when crushed with sulphuric acid, a brown color only. Its mesocarpic cells are in six or seven rows.

The *large false cubeb* of English commerce, commonly believed to be yielded by *Piper crassipes* of Korth, is a large, globular, brown or blackish fruit borne on a curved pedicel, usually at least twice as long as the fruit; the pedicel is not flattened, and is sometimes tapering, but never dilated, at its free extremity. The fruit measures from 7–8·5 Mm., and the pedicel 12–23 Mm. The taste is bitter, but does not leave a persistent burning sensation in the mouth. Sulphuric acid gives with the crushed fruit a yellow coloration. So far as De Wevre's examination went, *Piper crassipes* of Korth is identical with *Piper ribesioides* (Wallich).

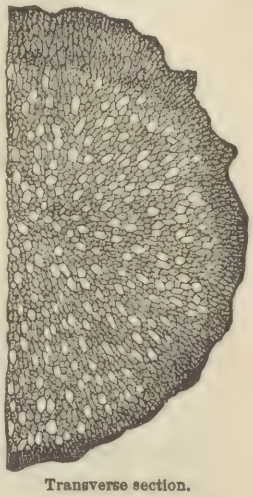
A *short pedicelled cubeb* which occurs in commerce, in which the feebly aromatic fruit is from 4 to 5 Mm. in diameter and the pedicel 1 Mm., is especially characterized by a layer of small cells under the epidermis, like those of the epidermis, by a hypodermal layer of three or four rows of polygonal uniform stone cells, and by the cubical cells of the endocarp being cutinized in horseshoe fashion,—that is, having the outside wall thinner than the other three (the reverse of what occurs in black pepper).

Keboe cubeb is much larger than the official, being about 7 Mm. in diameter, with a pedicel 16 Mm. long; the color is blackish or grayish black, the surface much wrinkled, the taste acrid, slightly bitter, and pungent, and the

Piper cubeba. Willd. *Sp. Plant.* i. 159; Woodv. *Med. Bot.*, 3d ed., v. 95.—*Cubeba officinalis.* Miquel. This is a climbing perennial plant, with a smooth, flexuous, jointed stem, and entire, petiolate, oblong or ovate-oblong, acuminate leaves, rounded or obliquely cordate at the base, strongly nerved, coriaceous, and very smooth. The flowers are dicœcious and in spikes, with peduncles about as long as the petioles. The fruit is a globose, pedicelled berry. This species of Piper is a native of Java, Penang, and probably other parts of the East Indies. It is extensively grown in the coffee plantations, supported by the trees which are used for shade, and has been introduced into Ceylon. The dried unripe fruit is the official portion.

Cubeb fruit. *A*, fruit itself, natural size; *C*, segment of the fruit, magnified; *tx*, ring of stony wall-cells; *l*, oil-cells; *D*, section of the seed; *l*, oil-tubes; *d*, epidermis.

Properties. Cubebs are round, about the size of a small pea, of a blackish or grayish-brown color, and furnished with a short stalk, which is continuous with raised veins that run over the surface of the berry and embrace it like a net-work. The shell is hard, almost ligneous, and contains within it a single loose seed, covered with a blackish coat, and internally white and oleaginous. "Globular, about 4 or 5 Mm. in diameter, contracted at the base into a rounded stipe about 6 or 8 Mm. long, reticulately wrinkled, blackish-gray, internally whitish and hollow; odor strong, spicy; taste aromatic and pungent. Cubeb should not be mixed with the nearly inodorous rachis or stalks." *U. S.* "A transverse section of the pericarp exhibits two layers of sclerenchymatous cells, one near the outer, the other near the inner surface, those of the latter being radially elongated. The crushed Fruit imparts a crimson color to *sulphuric acid*." *Br.* The odor of the berry is agreeably aromatic; the taste warm, bitterish, and camphorous, leaving in the mouth a peculiar sensation of coolness, like that produced by oil of peppermint. The pericarp



strong odor different from that of cubebs. It is said to be yielded by *Piper* (*Pothomorphe*) *mollissimum*, Bl., the *P. crassipes of Brunotte.*

The fruit of the *Daphnidium cubeba*, a rather common adulteration of cubebs, has been shown to be identical with that of *Tetranthera citrata*. It is especially characterized by its endocarp, which consists of long, narrow, sclerenchymatous cells, crowded closely together in a single line and arranged radially. The taste of the fruit is slightly bitter and aromatic, but not burning. It has usually no pedicel, and the pericarp contains a plainly dicotyledonous seed without albumen, whereas in the cubeb the embryo is too small for the naked eye to distinguish the cotyledons, the mass of the seed consisting of albumen. The cells of the endocarp have a very narrow linear cavity, and are very distinct from those of cubebs. Even the powder of *Daphnidium cubeba* is to be recognized from that of a Piper by the absence of small angular starch granules.

Among the other species of Piper whose berries have been found in cubebs,—in the African *P. clusii*, D. C., and *P. guineense*, Schum., and in the Javanese *P. lowong*, Bl., and *P. sylvestre*, Lam.,—neither the endocarp nor the hypoderm contains sclerenchymatous cells; whilst in *P. mollissimum*, Bl., the endocarp is not sclerenchymatous and the hypoderm very sparingly so. De Wevre refers to a species of Rhamnus certain adulterating berries which occur in the cubebs. These berries are nearly tasteless, with an odor somewhat resembling that of *Daphnidium cubeba*; are rounded and compressed laterally, with two rather deep furrows, separating the fruit into halves, and have, internally, two cells. Their powder is characterized by the presence of a great number of stone cells, entirely different in form from those of cubebs.

Mr. E. M. Holmes and Mr. E. D. Gravill (*P. J. Tr.*, vol. xv.) give the following tests which may be available in detecting powdered false cubebs. After being crushed, the genuine cubebs gives on a porcelain slab with concentrated sulphuric acid a deep crimson with a distinct carmine tint in it. *P. crassipes* strikes a reddish-brown color, *Daphnidium cubeba* a yellowish-brown color. Iodine gives with a decoction of genuine cubebs a pure blue tint, and with spurious cubebs a dull purple tint. One cubic centimetre of the tincture of true cubebs treated with ten cubic centimetres of strong sulphuric acid (sp. gr. 1·843) develops a deep violet color, the false cubebs similarly treated a deep red-brown. On diluting these mixtures with four fluidounces of distilled water and allowing them to stand, the true cubebs becomes opalescent and changes to a deep blue, the false becomes opalescent and changes to a dirty yellow. In applying these tests to adulterated cubebs, the color developed will, of course, be dependent upon the amount and character of the adulteration. An important conclusion reached by De Wevre is, that it is not possible to detect by microscopic examination with certainty the freedom of a powdered cubeb from adulteration with various berries, especially those yielded by different species of the genus Piper, although the presence of numerous polygonal stone cells would indicate adulteration, whilst the peculiar prismatic sclerenchymatous cells of the true cubeb indicate genuineness. It would seem to be essential for the pharmacist to buy his cubebs whole, and examine the fruit before powdering.

(Fig. *C*, *p.c*) of the cubeb berry consists of three layers, the exterior of which is composed of an interrupted row of small, thick-walled cubical sclerenchymatous cells arranged in irregular groups of three or four. The middle layer of the pericarp is composed of loose, undeveloped tissue, interspersed with large oil-cells, and contains quantities of starch and sometimes groups of needle-shaped crystals. The inner layer is free from starch, and is formed of four rows of parenchymatous cells. At the junction of the inner and middle layers there are usually from ten to twelve distinct woody bundles, chiefly composed of narrow spiral vessels along with a few dotted vessels (Fig. *C*, *m.c*). The mesocarp is composed of compressed parenchymatous cells, of which there are usually four rows, whilst the endocarp is formed of long sclerenchymatous cells arranged radially,—*i.e.*, on their ends (Fig. *C*, *e.c*). The testa consists of one row of large, thick-walled cells. The perisperm is surrounded by red membrane, formed of rather large cells, and is composed of angular parenchymatous cells containing starch and oil. On allowing thin sections to stand in glycerin for a few weeks, crystals are formed both in the pericarp and in the perisperm. The powder is dark-colored and of an oily aspect, and is microscopically characterized by the presence of prismatic sclerenchymatous cells. The most obvious constituent of cubebs is the volatile oil, the proportion of which yielded by the drug varies from 4 to 13 per cent. It is, as shown by Oglialoro, a mixture of an oil, $C_{10}H_{16}$ (*dipentene*), boiling at 158°–163° C. (316·4°–325·4° F.), which is present in very small amount, and two oils of the formula $C_{15}H_{24}$, boiling at 262°–265° C. (503·6°–509° F.). One of these, known as *cadinene*, is strongly lævogyrate, and yields a crystallized compound, $C_{15}H_{24}2HCl$, melting at 118° C., while the other is less lævogyrate, and does not combine with HCl.

Transverse section.

The oil distilled from old cubebs on cooling at length deposits large transparent inodorous octohedra of *camphor of cubebs*, $C_{15}H_{26}O$. E. Schmidt found that this camphor melts at 66·5° C.; simply by standing over sulphuric acid, more rapidly on heating, it gave up water and passed into that fraction of cubeb oil which boils at 260° C., of which it is, therefore, simply the hydrate. Another constituent of cubebs is *cubebin*. This is an inodorous substance, crystallizing in small needles or scales, melting at 125° C. (257° F.), having a bitter taste in alcoholic solution; it dissolves freely in boiling alcohol, but deposits on cooling, and is abundantly soluble in chloroform. Its composition, according to Weidel (1877), is $C_{10}H_{10}O_3$. Fused with caustic potash it yields proto-catechuic acid. The resin extracted from cubebs consists of an indifferent portion, nearly 3 per cent., and of *cubebic acid*, $C_{13}H_{14}O_7$, amounting to about 1 per cent. (*Pharmacographia*, 2d ed., p. 587.)

The formula of cubebic acid as just given is that of Schmidt. Schultze (*Jahresbericht*, 1873, p. 863), on the other hand, gives to it the formula $C_{28}H_{30}O_7 + H_2O$. According to MM. Capitaine and Soubeiran, *cubebin* is best obtained by expressing cubebs from which the oil has been distilled, preparing from them an alcoholic extract, treating this with a solution of potassa, washing the residue with water, and purifying it by repeated crystallizations in alcohol. It bears a close resemblance to piperin, but materially differs from it in composition, as it contains no nitrogen. (*Journ. de Pharm.*, xxv. 355.) In the official oleoresin of cubeb a deposit takes place consisting chiefly of cubebin, which may be obtained by washing the deposit with a small quantity of cold alcohol to remove adhering resin and oil, and then dissolving repeatedly in boiling alcohol, and crystallizing until the product is white.* The volatile oil is official. (See *Oleum Cubebæ*.) By practical trial Bernatzik has satisfied himself that the peculiar virtues of cubebs as a remedy in gonorrhœa depend not on the cubebin or the volatile oil, but on the cubebic acid. (See *Am. Journ. of Med. Sci.*, October, 1867, p. 534.) When the ethereal extract of cubebs is deprived of its volatile oil by evaporation, on a water-bath, and of cubebin and wax by deposition, a soft resin is left, the *cubebic acid* of Bernatzik, in which, according to Mr. F. V. Heydenreich, who experimented with it as a physiological agent, the diuretic properties reside, the cubebin being without apparent effect, and the volatile oil, though stimulant and carminative, having no diuretic action. The soft resin, which was of the consistence of honey, of a dark olive-green color, and some remaining odor of cubebs, when taken in the

* Prof. E. Schaer calls attention to the similarity in reaction between cubebin and veratrine, aconitine, morphine, and digitalin. (*Archiv d. Pharm.*, 1887, p. 531.)

dose of ten grains every two hours for six hours, acted as a laxative, and gave the urine a peculiar odor, without increasing its quantity; but in the dose of a drachm, once repeated at an interval of three hours, while it produced the same effects as the smaller dose, it considerably augmented the urine. In still larger doses it produced decided irritation of the urinary passages. (*A. J. P.*, Jan. 1868.) Mr. Heydenreich's experiments are confirmatory of Bernatzik's conclusion as to the peculiar active principles of cubebs. Cubebs gradually deteriorate by age, and in powder become rapidly weaker, in consequence of the escape of their volatile oil. They should be kept whole, and pulverized when dispensed. The powder is said to be sometimes adulterated with that of pimento.

Medical Properties and Uses. Cubebs are generally stimulant, with a special direction to the urinary organs. In considerable quantities they excite the circulation, increase the heat of the body, and sometimes occasion headache and giddiness. At the same time they frequently produce an augmented flow of the urine, to which they impart a peculiar odor. Among their effects are also occasionally nausea and moderate purging; and they are said to cause a sense of coolness in the rectum during the passage of the fæces. We have no evidence that they were known to the ancients. They were probably first brought into Europe by the Arabians, and were formerly employed for similar purposes with black pepper; but they were found much less powerful and fell into disuse. In India they have long been used in gonorrhœa and gleet, and as a grateful stomachic and carminative in disorders of the digestive organs, and they are at present very frequently given both in this country and in Europe in *gonorrhœa*, after the subsidence of the first active inflammatory symptoms. They have been given also in *leucorrhœa*, *cystirrhœa*, the *urethritis* of women and female children, *abscess of the prostate gland*, *piles*, and *chronic bronchial inflammation*. In connection with copaiba they have been especially recommended in affections of the neck of the bladder and the prostatic portion of the urethra. They are best administered in powder, of which the dose in gonorrhœa is from one to three drachms (3·9–11·65 Gm.) three or four times a day. For other affections, the dose is sometimes reduced to ten grains (0·65 Gm.). The volatile oil may be substituted, in the dose of ten or twelve drops (0·6–0·72 C.c.), suspended in water by means of sugar; though, if the experiments of Bernatzik and Heydenreich are to be relied on, the oil is much less efficient than the soft resin as a remedy in gonorrhœa and in diseases of the urinary passages generally. An ethereal extract is directed by the U. S. Pharmacopœia, and considerably used; and, as it contains the soft resin or cubebic acid, it is no doubt a very efficient preparation. (See *Oleoresina Cubebæ*.) An infusion, made in the proportion of an ounce of cubebs to a pint of water, has been employed as an injection in discharges from the vagina.

CUPRI SULPHAS. U. S., Br. Copper Sulphate. [Cupric Sulphate.]

$CuSO_4.5H_2O$; 248·8. (CŪ'PRĪ SŬL'PHĂS.) $CuSO_4.5H_2O$; 249·2.

"This salt, $CuSO_4,5H_2O$, may be obtained by the interaction of water, sulphuric acid, and copper or cupric oxide." *Br.*

Cuprum Sulfuricum, *P. G.;* Cuprum Vitriolatum; Blue Vitriol, Roman Vitriol, Blue Stone; Sulfate de Cuivre, Vitriol bleu, Couperose bleu, *Fr.;* Schwefelsaures Kupfer, Kupfersulfat, Kupfervitriol, Blauervitriol, Blauer Galitzenstein, *G.;* Rame solfato, Vitriolo di Rame, *It.;* Sulfato de Cobre, Vitriolo azul, *Sp.*

Preparation, etc. Copper sulphate occasionally exists in nature, in solution in the water which flows through copper-mines. In this case the salt is procured by merely evaporating the waters which naturally contain it. Another method of obtaining it is to roast the native sulphide in a reverberatory furnace, whereby it is made to pass, by absorbing oxygen, into the state of sulphate. The roasted mass is lixiviated, and the solution obtained evaporated that crystals may form. The salt procured by either of these methods contains a little ferric sulphate, from which it may be freed by adding either an excess of cuprous oxide, which precipitates ferric oxide, or recently precipitated copper subcarbonate, which causes the deposition of the iron as a carbonate. (*A. J. P.*, xxxiv. 507.) A third method is to dissolve copper scales to saturation in sulphuric acid contained in a wooden vessel lined with sheet lead. The scales consist of metallic copper mixed with oxide, and are produced in the process for annealing sheet copper.

Most of the copper sulphate produced at present is obtained as a bi-product by the gold, silver, and copper refiners. In 1895 there was produced in the United States 45,000,000 lbs. of copper sulphate, valued at $1,750,000; in 1896, 48,732,840 lbs., valued at $1,953,225; and in 1897, 51,012,945 lbs., valued at $2,040,518.

In the U. S. Pharmacopœia copper sulphate is presumed to be obtained pure from the manu-

facturer; the British Pharmacopœia suggests the method in which it may be prepared, without entering into the details of the process. The German Pharmacopœia has two kinds official, *Cuprum Sulfuricum*, which corresponds with the former *Cuprum Sulfuricum Purum*, and *Cuprum Sulfuricum Crudum*, or commercial sulphate.

Properties. Copper sulphate has a rich deep blue color, and a strong metallic styptic taste. It reddens vegetable blues, and crystallizes in "large, transparent, deep blue, triclinic crystals, odorless, of a nauseous, metallic taste; slowly efflorescent in dry air. Soluble, at 15° C. (59° F.), in about 2·6 parts of water, and in 0·5 part of boiling water; almost insoluble in alcohol. When carefully and continuously heated to 30° C. (86° F.), the salt loses 2 of its 5 molecules of water (14·43 per cent.), and is converted into a pale blue, amorphous powder. Two more molecules of water are lost at 100° C. (212° F.), while the fifth is retained until 200° C. (392° F.) is reached, when a white, anhydrous powder remains (63·9 per cent. of the original weight). At a still higher temperature sulphur dioxide and oxygen are given off, and a residue of black cupric oxide is left. The aqueous solution (1 in 20) has a blue color and shows an acid reaction with litmus paper. If a drop of the solution be placed upon a bright piece of iron, it will produce a red stain of metallic copper. With potassium ferrocyanide test-solution the solution yields a deep reddish-brown precipitate. Barium chloride test-solution produces a white precipitate, insoluble in hydrochloric acid. If ammonia water be added to the solution, drop by drop, a pale blue precipitate of cupric hydrate is formed, which redissolves in an excess of ammonia water, forming a deep azure-blue solution, leaving no trace of residue undissolved (absence of *iron*, *aluminum*, etc.) If the aqueous solution (1 in 20) be heated to boiling with an excess of sodium hydrate test-solution, until all of the copper has been converted into black cupric oxide, it will yield a filtrate which, after acidulation with acetic acid, should not be colored or rendered turbid by an equal volume of hydrogen sulphide test-solution (absence of *arsenic*, *lead*, *zinc*, etc.) If hydrogen sulphide gas be passed through 10 C.c. of the solution slightly acidulated with hydrochloric acid, until all the copper is precipitated as sulphide, the filtrate should, on evaporation, leave not more than a trace of residue (limit of *iron*, *aluminum*, *alkaline earths*, etc.)," *U. S.* "Soluble in 3·5 parts of cold *water*, forming a solution which strongly reddens *litmus;* very soluble also in *glycerin*, almost insoluble in *alcohol* (90 per cent.). It affords the reactions of copper and of sulphates. It should yield no characteristic reaction with the tests for lead, arsenium, zinc, or aluminium, and not more than the slightest reactions with the tests for iron." *Br.* When heated, copper sulphate first melts in its water of crystallization, and then dries and becomes white. If the heat be increased, it next undergoes the igneous fusion, and finally, at a high temperature, loses its acid, cupric oxide being left. Four of the molecules of water of crystallization can be driven off at 100° C. (212° F.); but the fifth only goes off at a temperature of from 220° C. (428° F.) to 240° C. (464° F.), when the anhydrous salt remains. Potassa, soda, and ammonia throw down from it a bluish-white precipitate of hydrated cupric oxide, which is immediately dissolved by an excess of the last-mentioned alkali, forming a rich deep blue solution, called *aqua sappharina*. It is decomposed by the alkaline carbonates, and by borax, lead acetate and subacetate, ferric acetate, silver nitrate, mercuric chloride, potassium tartrate, and calcium chloride, and it is precipitated by all astringent vegetable infusions. If it becomes very green on the surface by the action of the air, it contains ferric oxide. This oxide may also be detected by ammonia, which will throw it down along with the copper oxide, without taking it up when added in excess. When copper sulphate is obtained from the *dipping liquid* of manufacturers of brass or German silver ware, it is always contaminated with zinc sulphate, as pointed out by Mr. S. Piesse. This liquid is at first a mixture of sulphuric and nitric acids, but becomes, at last, nearly saturated with copper. When zinc is present in copper sulphate, it will be taken up by solution of potassa, added in excess, from which it may be thrown down, in white flocks, by a solution of bicarbonated alkali.

Medical Properties and Uses. Copper sulphate is irritant or mildly escharotic; and when in dilute solution, stimulant and astringent. At one time it was given in *epilepsy* and other nervous diseases; but at present it is never used internally, except for its influence upon the gastro-intestinal mucous membrane. In *chronic diarrhœa* with ulceration it is often a useful remedy. In doses of 5 grains it acts as a powerful, prompt emetic, without causing general depression or much nausea, but is too irritant to be used freely. Externally it is employed in solution as a stimulant to ill-conditioned ulcers, as an escharotic for destroying warts, fungous granulations, and callous edges, and as a styptic to bleeding surfaces. It is found, in not a few instances, to promote the cicatrization of ulcers, and is not infrequently

employed, with that view, as a wash for chancres. The preparation called *cuprum aluminatum* (*lapis divinus—pierre divine*) is made, according to the French Codex, by mixing, in powder, three ounces, each, of copper sulphate, potassium nitrate, and alum, heating the mixture in a crucible, so as to produce watery fusion, then mixing in a drachm of powdered camphor, and, finally, pouring out the whole on an oiled stone to congeal. The mass, when cold, is broken into pieces, and kept in a well-stopped bottle. It is often desirable to employ copper sulphate, as a caustic, in the form of pencil. Its tendency to effloresce interferes with its use in this way in the pure state. M. Llovet recommends for the purpose a mixture of one part of potassa-alum and two of copper sulphate, which are to be first powdered, and then gradually melted together in a porcelain vessel, and poured into moulds made of bronze. (*Gaz. des Hôp.*, Juillet 28, 1863.) Another mode of preparing *pencils of copper sulphate* is to rub briskly together four parts of that salt and one of borax, and to mould the plastic mass which results into the desired form. (*A. J. P.*, March, 1864, p. 106.) The best form is that of an elongated cone, made by selecting suitable crystals and turning them in a lathe to the desired form; or they may be made by filing the crystals, and finishing with sand-paper.

The dose of copper sulphate, as an astringent, is a quarter of a grain (0·016 Gm.); as an emetic, five grains (0·33 Gm.), repeated in fifteen minutes if necessary, but not oftener than once. As a stimulant wash, the solution may be made of the strength of two, four, or eight grains to the fluidounce of water. For its effects as a poison, see *Cuprum*.

CUPRUM. Copper.

Cu; 63·18. (CŪ'PRŬM.)

"Fine Copper wire, about No. 25 wire gauge, or about 0·02 inch." *Br.* 1885.

Cupreum Filum; Fil de Cuivre, Cuivre, *Fr.;* **Kupfer, Kupferdraht,** *G.;* **Rame,** *It.;* **Cobre,** *Sp.*

This metal is very generally diffused in nature, and exists principally in four states: as native copper, as an oxide, as a sulphide, and as a salt. Its principal native salts are the sulphate, carbonate, arsenate, and phosphate. In the United States it occurs in various localities, but especially in the neighborhood of Lake Superior, in Montana, Arizona, and East Tennessee. The principal producing copper-mines of Europe are those of Spain and Portugal and of Mansfeld in Germany. Chili and Japan are also relatively large producers at present.

The total production of copper in the United States has increased very rapidly in recent years, and now is more than half that of the world's annual production. It was for 1895, 386,453,850 lbs., valued at $36,944,988; for 1896, 479.806,183 lbs., valued at $51,003,397; for 1897, 510,190,789 lbs., valued at $56,325,055. The three most productive States are Montana, Michigan, and Arizona, in the order named, the first yielding fully half of the total. The consumption of copper in the United States for 1896 was 216,483,123 lbs., and the exports for the same year 281,905,217 lbs.

Properties. Copper is a brilliant, sonorous metal, of a reddish color, and very ductile, malleable, and tenacious. It has a slightly nauseous taste, and emits a disagreeable smell when rubbed. Its texture is granular, and its fracture hackly. Its sp. gr. is 8·92 to 8·95, and its fusing point 1398° C. (2538° F.) according to Daniell, being intermediate between the fusing points of silver and gold. Its atomic weight is given as 63·5, or, according to the most accurate determinations, 63·18. Exposed to the air it undergoes a slight tarnish. Its combinations are numerous and important. With oxygen it forms two well-characterized oxides, a red suboxide, better known as *cuprous* oxide, Cu_2O, and a black oxide, known as *cupric* oxide, CuO. While a cuprous chloride, iodide, and sulphide are known, it is the cupric oxide chiefly that unites with the common acids to form cupric salts. With metals copper forms numerous alloys, of which that with zinc, called brass, and that with tin, called bronze, are the most useful.

Characteristics. Copper is recognized by its color, and the effects of tests on the solution of its nitrate. This solution, with potassa, soda, and ammonia, yields a blue precipitate, soluble in excess of the latter alkali, with which it forms a deep azure-blue liquid. Potassium ferrocyanide occasions a brown precipitate of copper ferrocyanide, and a bright plate of iron immersed in the solution immediately becomes covered with a film of metallic copper.* Potassium ferrocyanide is a very delicate test for minute portions of copper in solution. Another test, proposed by M. Verguin, is to precipitate the copper in the metallic state on platinum by electro-chemical action. For this purpose a drop of the liquid to be examined is placed on

* Thoms (*Zeitsch. für Analyt. Chem.*, 94, 464) asserts that if to a solution too dilute to give a sensible reaction with potassium ferrocyanide be added a solution of potassium iodide, a yellow coloration is produced which becomes violet with starch paste. This test will show as little as 1 to 500,000.

a slip of platinum foil, and a slip of bright iron is brought in contact with the platinum and the liquid. If copper be present it will be instantly precipitated on the surface of the platinum.

Action on the Animal Economy. Copper in its pure state is perfectly inert, but in combination it is highly deleterious. Nevertheless a minute portion of the metal has been found in the human body. According to Millon, copper, when it exists in the blood, is, like the iron, attached to the red corpuscles. To bring the copper into a state favorable for ready detection, he advises that the blood, as it escapes from a vein, be received in about three times its bulk of water, and the mixture poured into a bottle of chlorine and agitated. The whole, upon being rapidly filtered, furnishes a liquid in which copper is readily detected. Wackenroder found copper in the blood of man, but does not consider it a constant and normal constituent. He also detected this metal in the blood of domestic animals living on a mixed diet, but not in their blood when nourished on vegetable food only. (*Chem. Gaz.*, May 1, 1854.) It has been found in the feathers of certain birds, as of a grass-green paroquet from Australia, which is said to frequent districts of the country where copper is found. (*Ibid.*, Oct. 24, 1873, p. 212.) The soluble combinations of copper, when taken in poisonous doses, produce a coppery taste in the mouth; nausea and vomiting; violent pain in the stomach and bowels; frequent black and bloody stools; small, irregular, sharp, and frequent pulse; faintings; burning thirst; difficulty of breathing; cold sweats; paucity of urine, and burning pain in voiding it; violent headache; cramps, convulsions, and finally death. The best antidote is the potassium ferrocyanide, given freely, which forms with the poison the very insoluble copper ferrocyanide. Soap and alkalies are also antidotal. Before the antidote can be procured, large quantities should be given of milk, and white of eggs mixed with water, which act favorably by forming copper caseate and copper albuminate; but these compounds should be evacuated as soon as possible by vomiting and purging. Should vomiting not take place, the stomach-pump may be employed. The symptoms of slow poisoning by copper are, according to Dr. Corrigan, of Dublin, a cachectic appearance, emaciation, loss of muscular strength, colicky pains, cough without physical signs, and retraction of the gum, with a persistent purple edge, quite distinct from the blue edge produced by lead. (*Braithwaite's Retrospect*, Am. ed., xxx. 303.) But there is much doubt whether these symptoms can be produced by the metal. (See H. C. Wood's *Therapeutics*.)

In medico-legal examinations, where cupreous poisoning is suspected, Orfila recommends that the viscera be boiled in distilled water for an hour, and that the matter obtained by evaporating the filtered decoction to dryness be carbonized by nitric acid. The carbonized product will contain the copper. By proceeding in this way there is no risk of obtaining the copper which may happen to pre-exist in the animal tissues. This method of search is preferable to that of examining the contents of the stomach and intestines, from which copper may be absent, while it may have penetrated the different organs by absorption, especially the abdominal viscera.

Vessels of copper which are not coated with tin should not be used in pharmaceutical or culinary operations; for, although the metal uncombined is inert, yet the risk is great that the vessels may be acted on and a poisonous salt formed.

CUSPARIÆ CORTEX. Br. Cusparia Bark.

(CŬS-PĀ'RĮ-Æ CÖR'TĔX.)

"The dried bark of Cusparia febrifuga, DC." *Br.*

Angustura, *U. S.* 1870; Angusture, *Fr.;* Angusturarinde, *G.;* Corteccia dell' Angustura, *It.;* Corteza de Angostura, *Sp.*

This bark was dropped from the U. S. Pharmacopœia at the revision of 1880.

The subject of Angustura bark in its botanical relations has been involved in some confusion. The drug was at first supposed to be derived from a species of Magnolia, and was referred by some to *Magnolia glauca* of this country. Humboldt and Bonpland were the first to throw light upon its true source. When at Angostura, a South American city on the Orinoco, they received specimens of the foliage of the plant from which the bark was obtained, and afterwards believed that they had found the same plant in a tree growing in the vicinity of Cumana. This latter they had the opportunity of personally inspecting, and were therefore enabled to describe accurately. Unable to attach it to any known genus, they erected it into a new one with the title of *Cusparia*, a name of Indian origin, to which they added the specific appellation of *febrifuga*. On their authority, *Cusparia febrifuga* was generally believed to be the true source of the medicine, and was recognized as such by the London College. A specimen having in the mean time been sent by them to Willdenow, the name of *Bonplandia* was

imposed on the new genus by that celebrated botanist, and it was subsequently adopted by Humboldt and Bonpland themselves, in their great work on equinoctial plants. Hence the title of *Bonplandia trifoliata*, by which the tree is described in many works on Materia Medica. De Candolle, however, having found in the description all the characters of the genus *Galipea* of Aublet, rejected both these titles, and substituted that of *Galipea cusparia*, which was adopted by the London College, and for a time was retained in the British Pharmacopœia. But, after all these changes, it appears from the researches of Dr. Hancock, who resided for several months in the country of the Angustura bark tree, that it is doubtful whether the plant described by Humboldt and Bonpland is that which yields the medicine, and is not another species of the same genus. Among other striking differences between them is their different sizes; the tree described by Humboldt and Bonpland being at least sixty feet high, while that from which the bark is obtained is said to be never more than twenty feet. Hancock proposed for the plant of the Orinoco the title of *Galipea officinalis*, which was adopted in the U. S. P. 1870. This name was afterwards changed by Hancock to *Cusparia officinalis* (Syn. *C. trifoliata* H. et B., also (Willd.) Engl., and *Angostura Cuspare*, R. et Sch. of New Granada and Cumana). Nat. ord. Rutaceæ.

Cusparia febrifuga, DC.—*Cusparia officinalis*. Hancock, *Trans. Lond. Medico-Bot. Soc.*—*Galipea cusparia*. St.-Hilaire, *B. & T.*, vol. i. 43. This is a small tree, irregularly branched, rising to the medium height of twelve or fifteen feet, with an erect stem from three to five inches in diameter, and covered with a smooth gray bark. The leaves are alternate, petiolate, and composed of three leaflets, which are oblong, pointed at each extremity, from six to ten inches in length, from two to four in breadth, and supported upon the common petiole by short leafstalks. They are very smooth and glossy, of a vivid green color, marked occasionally with small whitish round spots, and, when fresh, of a strong odor resembling that of tobacco. The flowers are numerous, white, arranged in axillary and terminal peduncled racemes, and of a peculiar unpleasant odor. The fruit consists of five bivalve capsules, of which two or three are commonly abortive. The seeds, two of which are contained in each capsule, one often abortive, are round, black, and of the size of a pea. The tree grows abundantly on the mountains of Carony, between the 7th and 8th degrees of N. latitude, and is well known in the missions near the Orinoco, upwards of two hundred miles from the ocean. It flourishes at the height of from six hundred to one thousand feet above the level of the sea. Its elegant white blossoms, which appear in vast profusion in August and September, add greatly to the beauty of the scenery.

The bark is generally brought from the West Indies packed in casks; but, according to Mr. Brande, the original package as it comes from Angostura consists of the leaves of a species of palm, surrounded by a net-work of sticks.

Properties. "Occurs in flattened or curved pieces, or in quills, generally about four or five inches (ten or twelve centimetres) long, an inch (twenty-five millimetres) wide, and one-twelfth of an inch (two millimetres) thick. The outer layer usually consists of a gray or yellowish cork which is often soft and easily removed, disclosing a hard, dark brown inner layer; the inner surface is light brown and frequently laminated. The fracture is short and resinous; on the fractured surface many white points are visible. A transverse section exhibits numerous cells filled with acicular crystals of calcium oxalate and small oil glands, but seldom any sclerenchymatous tissue other than small isolated groups of bast fibres. Odor musty; taste bitter." *Br.* Calcium oxalate raphides are abundant in the bark, but the most characteristic peculiarity is the presence of numerous cells a little larger than the other parenchymatous cells and completely filled with oil or a yellowish resin.* The smell of Angustura bark is peculiar and disagreeable when fresh, becoming fainter with age; the taste is bitter and slightly aromatic, leaving a sense of pungency at the end of the tongue. According to Fischer, it contains volatile oil, bitter extractive, a hard and bitter resin, a soft resin, a substance analogous to caoutchouc, gum, lignin, and various salts. Oberlin and Schlagdenhauffen (1878) found in the bitter extractive an alkaloid, *angosturine*, $C_{10}H_{40}NO_{14}$, which melts at 85° C., is crystallizable, and is turned red by pure sulphuric acid, and green by sulphuric acid with admixture of nitric acid. The volatile oil, which may be obtained by distillation with water, is of a pale yellowish color, lighter than water, of an acrid taste, and with the odor of the bark. Its formula is given as $C_{13}H_{24}O$ by Dr. C. Herzog, who states that its boiling point is 266·1° C. (511° F.), probably one of the highest of the volatile oils. The *cusparine* of Saladin has not been found by other investigators. Beckurts and Nehring (*A. J. P.*, 1892, 410) announced the discovery of four alkaloids in Angustura bark,—viz., *galipine*, $C_{20}H_{21}NO_3$, melting at

* For an elaborate microscopical study of the bark, see *Journ. de Pharm.*, xxviii. 230.

115·5° C. and crystallizing in slender lustrous needles of white color; *galipidine*, $C_{19}H_{19}NO_3$, melting at 111° C. and crystallizing in silky lustrous plates of white color; *cusparine*, $C_{20}H_{19}NO_3$ ($C_{19}H_{17}NO_3$, Körner), melting at 89° C. and readily soluble in alcohol, ether, chloroform, acetone, and benzene, more sparingly in light petroleum; and *cusparidine*, $C_{19}H_{17}NO_3$, melting at 78° C. and crystallizing in minute slender white needles. Its salts are less soluble than those of galipine and galipidine, but more readily than those of cusparine. The four alkaloids are tertiary bases. (See also *Archiv d. Pharm.*, 233 (1895, No. 6) 410.) Beckurts and Nehring also extracted the essential oil, amounting to 1·5 per cent. It had a sp. gr. at 15° C. of 0·956. Distilled under a pressure of 35 Mm. it commenced to boil at 153° C., and the greater part distilled between 200° and 220° C., the last portions becoming solid when artificially chilled. (See also *Archiv d. Pharm.*, 1897, 518.) They found the bitter principle *angosturine*, which when purified was whitë and melted at 58° C. A glucoside was also found, the solution of which fluoresced; but it was not fully investigated.

Dr. A. T. Thomson states that precipitates are produced with the infusion by the solutions of ferrous sulphate, antimony and potassium tartrate, copper sulphate, lead acetate and subacetate, mercuric chloride, silver nitrate, and pure potassa, by nitric and sulphuric acids, and by the infusions of galls and yellow cinchona; but how far these substances are medicinally incompatible with the bark it would be difficult to determine.

False Angustura. Under this title, European writers describe a bark which was introduced on the Continent mixed with true Angustura bark, and, being possessed of poisonous properties, produced in some instances unpleasant effects when dispensed by mistake for that medicine. It is distinguished by its greater thickness, hardness, weight, and compactness; by its resinous fracture; by the appearance of its epidermis, which is sometimes covered with a ferruginous efflorescence, sometimes is yellowish gray and marked with prominent white spots; by the brownish color and smoothness of its internal surface, which is not, like that of the genuine bark, separable into laminæ; by the white slightly yellow powder which it yields; by its total want of odor, and its intense tenacious bitterness. When steeped in water it does not become soft, like the true Angustura. Pelletier and Caventou found it to contain *brucine*. (See *Nux Vomica*.) In consequence of the presence of this principle, a drop of nitric acid upon the internal suface of the bark produces a deep red spot. The same acid, applied to the external surface, renders it emerald-green. In true Angustura bark a dull red color is produced by the acid on both surfaces. The *false Angustura* was at first supposed to be derived from *Brucea antidysenterica*, but at present is ascribed to *Strychnos nux vomica*. (See also *A. J. P.*, 1892, 115, and *P. J. Tr.*, 1895, 722.)

Brazilian Angustura Bark, the product of *Esenbeckia febrifuga*, consists of slightly curved pieces 8 to 10 inches long, about $\frac{1}{16}$ of an inch in thickness, of a persistently bitter taste. The outer surface is usually ashen gray, and always marked with longitudinal red or black spots on a yellow ground; the inner surface is reddish, with paler, distinct, elongated fibres. On maceration the bark does not swell. (Oberlin and Schlagdenhauffen, *Journ. de Pharm.*, xxviii.)

Medical Properties and Uses. Angustura bark had been long used by the natives of the countries where it grows before it became known elsewhere. From the continent its employment extended to the West Indies, where it acquired considerable reputation, and about eighty years since it was introduced into Europe. Its operation is that of a stimulant tonic. In large doses it also evacuates the stomach and bowels, and is often employed for this purpose in South America. It is said to be peculiarly efficacious in bilious *diarrhœas* and *dysenteries*, and has been recommended in *dyspepsia* and other diseases requiring a tonic treatment. The testimony, however, of practitioners in Europe and the United States is not strongly in its favor; and it is probably better adapted to tropical diseases than to those of temperate climates.

It may be given in powder, infusion, tincture, or extract. The dose in substance is from ten to thirty grains (0·65–1·95 Gm.). In larger quantities it is apt to produce nausea. From five to fifteen grains (0·33–1 Gm.) is the dose of the extract, which, however, according to Dr. Hancock, is inferior to the powder or infusion. To obviate nausea, it is frequently combined with aromatics. (See *Infusum Cuspariæ*.)

CUSSO. U. S., Br. Kousso. [Brayera, Pharm. 1880.]

(cūs'sō.)

"The female inflorescence of Hagenia Abyssinica (Bruce), Gmelin (nat. ord. Rosaceæ.)" *U. S.* "The dried panicles of pistillate flowers of Brayera anthelmintica, Kunth." *Br.*

Koosso; Flores Kosso, *P. G.*; Kusso, *E.*; Cousso, Kousso, *Fr.*; Kosso, Kusso, Cusso, *G.*

Hagenia abyssinica. Willd. *B. & T.* 102.—*Brayera anthelmintica.* Kunth; De Cand. *Prodrom.* ii. 580; Pereira, *Mat. Med.*, 3d ed., ii. 1818.—*Banksia abyssinica.* Bruce. This is a tree about twenty feet high, growing on the table-land of Abyssinia, at an elevation of from three thousand to eight thousand feet. The branches exhibit circular cicatrices, left by the fallen leaves. These are crowded near the ends of the branches, large, pinnate, sheathing at the base, with opposite, lanceolate, serrate leaflets, villose at the margin, and nerved beneath. The unisexual flowers are tinged with purple, pedicelled, with an involucre of four roundish, oblong, obtuse, membranous bracts, and are arranged in fours, upon hairy, flexuous, bractate peduncles, with alternate branches. They are small and of a greenish color, becoming purple. These and the unripe fruit are the parts of the plant employed. The petals are apt to be wanting in the dried flowers. They are brought from Abyssinia packed in boxes, reaching Europe chiefly by way of Aden and Bombay. The Abyssinian name of the medicine has been variously spelled by European writers kosso, koosso, cusso, cosso, etc. The fruit of the tree is said to be used as an anthelmintic in Abyssinia, but Dragendorff failed to detect any active principle in it.

Properties. The dried flowers are in unbroken though compressed clusters. The male flowers are usually collected, so that ordinarily the general color of the mass is greenish yellow or light brown; sometimes the female flowers constitute the bulk of the drug, which then has a distinct reddish tint, and is often known in commerce as *red kousso.* In accordance with our Pharmacopœia, this commercial variety should alone be used. The male flowers are often found mixed with the female flowers, when loose (not in bundles) as high as 12 per cent. of this adulteration having been noticed by Meyer and Sandlund. (*Pharm. Zeit.*, 1893, No. 99.) The official description is as follows: "In bundles, rolls, or compressed clusters, consisting of panicles about 25 Cm. long, with a sheathing bract at the base of each branch; the two roundish bracts at the base of each flower, and the four or five obovate, outer sepals, are of a reddish color, membranous and veiny; calyx top-shaped, hairy, enclosing two carpels or nutlets; odor slight, fragrant, and tea-like; taste bitter, acrid, and nauseous." *U. S.* As the medicine, from its high price, is apt to be adulterated, it should be procured in the unpowdered state, in which the botanical characters of the flower will sufficiently test its genuineness. It has a fragrant balsamic odor; and the taste, slightly perceptible at first, becomes in a short time somewhat acrid and disagreeable. Analyzed by Wittstein, it was found to contain, in 100 parts, 1·44 of fatty matter and chlorophyll, 2·02 of wax, 6·25 of bitter acrid resin, 0·77 of tasteless resin, 1·08 of sugar, 7·22 of gum, 24·40 of tannic acid, 40·97 of lignin, 15·71 of ashes, with 0·14 part of loss. In 1855 it was studied by Clemens Willing (*Chem. Centralbl.*, 1855, 224), who found a small quantity of tannin, volatile oil, crystallizable acid, and a bitter resin. In 1858 Pavesi (*Viertelj. f. Prak. Pharm.*, viii. 505) made a further chemical study of the drug; but we are chiefly indebted to Dr. Bedall, of Munich, for determining that the bitter acrid resin of Wittstein is equivalent to the tæniin of Pavesi, and for the name of *kosin.* It may be obtained by treating kousso repeatedly with alcohol to which calcium hydrate has been added; the residue is boiled with water, the liquids are mixed, filtered, and distilled, and the residue treated with acetic acid, which precipitates the kosin in a white flocculent form, soon becoming denser and resin-like, and, on drying, yellowish, or, at a higher temperature, brown. The product is 3 per cent. In bulk, kosin has an odor like that of Russian leather, a persistent bitter and acrid taste, a yellowish or yellowish-white color, and an indistinct crystalline appearance under the microscope. It is very sparingly soluble in water, but freely so in alcohol, ether, and alkaline solutions. (*A. J. P.*, 1872, 394.) Its formula, according to Flückiger, is $C_{31}H_{38}O_{10}$. It fuses at 142° C. (287·6° F.), and remains after cooling an amorphous yellow mass, but if touched with alcohol it immediately assumes the form of stellate tufts of crystals. This may be repeated at pleasure, kosin not being altered by cautious fusion. (*Pharmacog.*, 2d ed., 258.) Leichsenring (*Archiv d. Pharm.*, 1894, 50) has reexamined kousso, and finds an inactive crystalline principle to which he gives the name *protokosine*, and an amorphous substance, *kossotoxine*, which he considers the active principle of the drug; the latter is a yellowish powder, fusing at 80° C., and not obtainable in a crystalline state. It is easily soluble in alcohol, ether, benzol, carbon disulphide, and insoluble in water.

Koussinate of Sodium has been recommended by Pavesi as a very eligible preparation for obtaining the virtues of kosin: a process is given in *Amer. Drug.*, 1884, 96; *A. J. P.*, 1885.

Medical Properties. Koosso is highly valued in Abyssinia as a vermifuge. Bruce speaks of it in his travels, and gives a figure of the plant. Dr. Brayer, a French physician

practising in Constantinople, published a treatise on it at Paris in 1823. It was in his honor that Kunth adopted the generic title of the plant. Much attention has recently been attracted to this medicine; and trials made with it have proved that it has extraordinary efficacy in the destruction and expulsion of the *tape-worm*. Its effects when taken internally are not very striking. In the ordinary dose it sometimes produces heat of stomach, nausea, and even vomiting, and shows a tendency to act on the bowels, though this effect is not always produced. It appears to act exclusively as a poison to the worms, and has been found equally effectual in both kinds of tape-worm. The medicine is taken in the morning upon an empty stomach, a light meal having been made the preceding evening. A previous evacuation of the bowels is also recommended. The flowers are given in the form of powder, mixed with half a pint of warm water, the mixture being allowed to stand for fifteen minutes, then stirred up, and taken in two or three draughts at short intervals. The medicine may be preceded and followed by lemonade. The medium dose for an adult is half an ounce (15·5 Gm.), which may be diminished one-third for a child of twelve years, one-half for one of six years, and two-thirds for one of three years. Should the medicine not act on the bowels in three or four hours, a brisk cathartic should be administered. One dose is said to be sufficient to destroy the worm. Should the quantity mentioned not prove effectual, it may be increased to an ounce (31·1 Gm.).

Pure kosin has been considerably used in Germany in doses of thirty grains (2 Gm.), taken in two or four powders; but Buchheim found *pure* kosin less powerful as an anthelmintic than that which was not pure, whilst Arena (*Pharm. Zeitschr. f. Russl.*, 1879, 655) believes that kosin is not the active principle at all, but that the activity of koosso resides exclusively in the green, slightly bitter resin, which is soluble in alcohol and ether. If this view be correct, it explains the greater efficacy of freshly powdered koosso, for the green resin turns yellow by age and loses its power (see *Extractum Cusso*), and further indicates that the amorphous kosin of commerce is preferable to the pure principle. It is a yellowish-brown mass, which may be given in doses of from seven to fifteen grains (0·5–1 Gm.), repeated every half-hour until four doses are taken, to be followed in an hour by a full dose of castor oil. So far as we know, no cases of poisoning by koosso or its active principle are on record; but it has been found by Rochebrune to be capable of causing centric convulsions in the lower animals.

CYPRIPEDIUM. U.S. Cypripedium. [Ladies' Slipper.]

(ÇĬP-RĮ-PĒ′DĮ-ŬM.)

"The rhizome and roots of Cypripedium pubescens, Swartz, and of Cypripedium parviflorum, Salisbury (nat. ord. Orchideæ)." *U. S.*

Rhizoma Cypripedii; Ladies' Slipper Root; Racine de Cypripède jaune, Valériane américaine, *Fr.*; Gelbfrauenschuh-Wurzel, *G.*

Under the common name of *ladies' slipper*, or *moccasin plant*, several species of Cypripedium inhabit the woods in different parts of the United States. They are small plants, with large, many-nerved, plaited leaves, sheathing at the base, and large often beautiful flowers, of a shape not unlike the Indian moccasin, whence they derive one of their common names. Their generic name of Cypripedium (*Κύπρις*, *Venus*, and *πόδιον*, *sock*) had a similar origin. Several of them have been used by American physicians, the root being the part employed. Dr. R. P. Stevens, of Ceres, Pennsylvania, says of them that he has found the *C. spectabile* and *C. acaule*, especially when growing in dark swamps, to be possessed of narcotic properties, and to be less safe than the *C. parviflorum*, which is gently stimulant with a tendency to the nervous system, and is quite equal to valerian. He has employed it advantageously in *hysteria*, and in the pains of the joints following scarlet fever. (*N. Y. Journ. of Med.*, iv. 359.) Dr. E. Ives considers *C. pubescens*, *C. spectabile*, and *C. humile* identical in their effects, but *C. pubescens* the most powerful. (*Trans. Am. Med. Assoc.*, iii. 312.) The roots of the two species *C. pubescens* and *C. parviflorum* are indiscriminately kept in the shops and sold by the same name.

Cypripedium pubescens. Willd. *Sp. Plant.*, 1805, iv. 142. (*C. hirsutum*, Mill. *Gard. Dict.*, 1768.) The *yellow ladies' slipper*, as this plant is called from the color of its flowers, has a simple often flexuous, pubescent, leafy stem, from one to two feet high. The leaves are pubescent, ovate-lanceolate, acuminate, narrowing at the base, about four or five inches long by two in breadth, alternate, sessile, and sheathing. The flower is usually solitary and terminal, with four divisions of the perianth, the two outer cohering nearly to the apex, the inner longer, narrower, undulatory or twisted, and the lip an inch or two in length, swelling sac-like, and of

a yellow color. The fruit is an oblong capsule, tapering at each end, recurved, pubescent, and peduncled. The plant is indigenous, growing abundantly in rich, moist woods throughout the United States.

Cypripedium parviflorum. (Salisbury.) *Common Ladies' Slipper. Small-flowered Ladies' Slipper.* This is a perennial plant with a leafy stem, a foot or two in height, and comparatively small yellowish-green flowers, appearing in May. The specific character of the flower, which is that also of the plant, is that the lobe of the style is triangular and acute; the outer petals are oblong-ovate and acuminate; the inner linear and contorted; the lips shorter than the petals, and compressed. This species grows extensively through the United States south of the Potomac, east and west of the Alleghanies, and in several of the Northern States, particularly New York, Michigan, Connecticut, and Vermont. In Pennsylvania, especially near Philadelphia, it does not appear to prevail, and it is not mentioned in Darlington's *Flora Cestrica* as among the plants of Chester County.

The rhizome is from two to four inches long. "Of horizontal growth, bent, 10 Cm., or less, long; from 3 to 5 Mm. thick; on the upper side beset with numerous circular, cup-shaped scars; closely covered below with simple, wiry roots varying from 10 to 15 Cm. in length; brittle, dark brown or orange-brown; fracture short, white; odor peculiar, heavy; taste sweetish, bitter, and somewhat pungent." *U. S.* Prof. Maisch gives a distinctive description of the roots of the two species, of which the following is a condensed account. Of *C. pubescens* the rhizome is almost horizontal, in its greatest length nearly four inches, slightly bent with a shallow downward curve, from $\frac{1}{8}$ to $\frac{3}{16}$ of an inch thick, with numerous deeply concave scars left by the stems, having fully the width of the rhizome. The rootlets are numerous, several inches in length, sometimes even nine inches or more, about $\frac{1}{14}$ of an inch thick, without branches, somewhat undulate, and, though attached to the rhizome on all sides, are abruptly turned downward, owing to its horizontal position in the ground. Their color is yellowish brown, becoming much darker on drying, which causes longitudinal wrinkles. The cortical part of both species is colored blue by iodine. The rhizome of *C. parviflorum* is altogether different from the former, being bent nearly at right angles three or four times, each section about $\frac{3}{4}$ of an inch long; and the whole length, while only about two inches in a straight line from end to end, is yet actually three inches along the course of the rhizome. This is about $\frac{1}{8}$ of an inch thick, and has stem-scars about the same in width, with about three in each bend. The rootlets, which are attached to all sides of the rhizome, are numerous, four to six inches long, less undular than those of *C. pubescens*, and of a brighter color, being a decided orange-brown when fresh, and changing little on drying. (*A. J. P.*, 1872, 297.) Poisonous properties have been attributed to *C. spectabile* and *C. pubescens* (see *Geol. Nat. Hist. Survey, Minnesota Bull.*, 9, part i.), but it has been shown that the secretion from the glandular hairs simply exerts an irritant action.

The roots of the Cypripedia are sometimes mixed, as brought into the market, with those of *Hydrastis canadensis*, from the plants occasionally growing in close contiguity. (See *Hydrastis.*) Roots of seneka have also been noticed in specimens of Cypripedium; but there can be no difficulty in distinguishing them.

Properties. Cypripedium has a somewhat aromatic odor, which diminishes by time, and a bitter, sweetish, peculiar, and in the end somewhat pungent taste. It yields its virtues to water and alcohol. The root has been analyzed by Mr. Henry C. Blair, who found it to contain a volatile oil, a volatile acid, tannic and gallic acids, two resins, gum, glucose, starch, and lignin. (*A. J. P.*, 1866, p. 494.) The so-called eclectics prepare what they improperly call *cypripedin* by precipitating with water a concentrated tincture of the root. The substance thus obtained is complex, and has no claim to the name given it, which ought to be reserved for the active principle when discovered. It is probable that the virtues of the root reside in a volatile oil and a bitter principle.

Medical Uses. Cypripedium appears to be a gentle nervous stimulant or antispasmodic, and has been used for the same purposes as valerian, though less powerful. Dr. E. Ives, of New Haven, Conn., commends the remedy in *hypochondriasis, neuralgia*, and morbid sensitiveness of the nervous system generally, and especially of the eye. It may be used in powder, infusion, or tincture. The dose of the powder given by Dr. Ives was fifteen grains (1 Gm.) three times a day. The oleoresin, obtained by precipitating the tincture, has been given in doses varying from half a grain to three grains (0·03–0·20 Gm.). (See *Extractum Cypripedii Fluidum.*)

DECOCTA. Decoctions.

(DĒ-CŎC'TĄ.)

Décoctions, *Fr.;* **Abkochungen,** *G.*

Decoctions are solutions of vegetable principles, obtained by *boiling* the substances containing these principles in water. Vegetables generally yield their soluble ingredients more readily, and in larger proportion, to water maintained at the point of ebullition, than to the same liquid at a lower temperature. Hence decoction is occasionally preferred to infusion as a mode of extracting the virtues of plants, when the call for the remedy is urgent, and the greatest possible activity in the preparation is desirable. The process should be conducted in a covered vessel, so as to confine the vapor over the surface of the liquid, and thus prevent the access of atmospheric air, which sometimes exerts an injurious agency upon the active principle. The boiling, moreover, should not, as a rule, be long continued; as the ingredients of the vegetable are apt to react on one another, and thus lose, to a greater or less extent, their original character. The substance submitted to decoction should if dry be either powdered or well bruised, if fresh should be sliced, so that it may present an extensive surface to the action of the solvent; and previous maceration for some time in water is occasionally useful by overcoming the cohesion of the vegetable fibre. Should the physician not happen to prescribe this preliminary comminution, the pharmacist should not omit it.

All vegetable substances are not proper objects for decoction. In many the active principle is volatile at a boiling heat, in others it undergoes some change unfavorable to its activity, and in a third set is associated with inefficient or nauseous principles, which, though insoluble or but slightly soluble in cold water, are abundantly extracted by that liquid at the boiling temperature, and thus encumber, if they do not positively injure, the preparation. In all these instances, infusion is preferable to decoction. Besides, by the latter process more matter is often dissolved than the water can retain, so that upon cooling a precipitation takes place and the liquid is rendered turbid, and this constitutes the greatest objection to this class of preparations. When the active principle is thus dissolved in excess, the decoction should always be strained while hot, so that the matter which separates on cooling may be mixed again with the fluid by agitation at the time of administering the remedy. In compound decoctions, the ingredients may be advantageously added at different periods of the process, according to the length of boiling requisite for extracting their virtues; and, should one of them owe its activity to a volatile principle, the proper plan is, at the close of the process, to pour upon it the boiling decoction, and allow the liquor to cool in a covered vessel.

As a rule, glass or earthenware vessels should be preferred, as those made of metal are sometimes corroded by the ingredients of the decoction, which thus become contaminated. Vessels of clean cast-iron or common tin, or of block tin, are preferable to those of copper, brass, or zinc; but iron pots should not be used where astringent vegetables are concerned.

Decoctions, from the mutual reaction of their constituents, as well as from the influence of the air, are apt to spoil in a short time. Hence they should be prepared only when wanted for use, and should not be kept, in warm weather, for a longer period than forty-eight hours.

The tendency of modern medicine and pharmacy has been decidedly against the employment of decoctions; the nauseous taste, bulky dose, repulsive appearance, and non-permanent character have been powerful reasons for causing their retirement, whilst the use of tinctures and fluid extracts has largely increased. In the 1880 revision of the U. S. Pharmacopœia the number of official decoctions was reduced to two, and a general formula was appended for the guidance of the pharmacist. The U. S. P. 1890 reduced the strength of the decoctions from 10 per cent. to 5 per cent., as will be seen from the following. "An ordinary Decoction, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula: Take of the Substance, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Put the substance into a suitable vessel provided with a cover, pour upon it *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of cold Water, cover it well, and boil for fifteen minutes. Then let it cool to about 40° C. (104° F.), express, strain the expressed liquid, and pass enough cold Water through the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

"*Caution.* The strength of Decoctions of energetic or powerful substances should be specially prescribed by the physician." *U. S.* The decoctions which were official in 1870 but dropped at the 1880 revision are *Decoctions of Pipsissewa, Yellow Cinchona, Red Cinchona,*

Dogwood, *Bittersweet*, *Logwood*, *Barley*, *White Oak*, *Seneka*, and *Uva Ursi*. With the exception of decoction of barley, these were all made by boiling a troyounce of the drug with a pint of water for fifteen minutes, straining, and adding sufficient water through the strainer to make the decoction measure a pint.

DECOCTUM ALOES COMPOSITUM. Br. Compound Decoction of Aloes.

(DĒ-CŎC'TUM ĂL'Ō-ĒS CŌM-PŎS'Ĭ-TŬM.)

Tisane (Décocté) d'Aloès composée, *Fr.;* Zusammengesetztes Aloedecoct, *G.*

"Extract of Barbados Aloes, ½ *ounce* (Imperial) or 10 grammes; Myrrh, Saffron, Potassium Carbonate, of each, ¼ *ounce* (Imp.) or 5 grammes; Extract of Liquorice, 2 *ounces* (Imp.) or 40 grammes; Compound Tincture of Cardamoms, 15 *fl. ounces* (Imp. meas.) or 300 cubic centimetres; Distilled Water, *a sufficient quantity*. Reduce the Extract of Barbados Aloes and the Myrrh to coarse powder, and boil them and the Potassium Carbonate and the Extract of Liquorice with *one pint* (Imp. meas.) or four hundred cubic centimetres of Distilled Water in a covered vessel for five minutes; add the Saffron; when the liquid is cool add the Tincture of Cardamoms; set aside in the covered vessel for two hours; strain through flannel; pass sufficient Distilled Water through the strainer to make *fifty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Compound Decoction of Aloes." *Br.*

This is essentially the former process of the British Colleges. The direction is properly given to rub the aloes, myrrh, and potassium carbonate together before the addition of the other ingredients. The effect of the alkaline carbonate is, by combining with the resin of the myrrh and the insoluble portion of the aloes, to render them more soluble in water, while the liquorice assists in the suspension of the portion not actually dissolved. The tincture of cardamom is useful not only by its cordial property, but also by preventing spontaneous decomposition. This decoction is said not to filter clear when first made, but, if kept for some time, to deposit insoluble matter, and then to become bright and clear on filtering. (*P. J. Tr.*, xiv. 491.) J. F. Brown proposes to prepare a concentrated decoction which keeps for a time unchanged. (*Chem. and Drug.*, 1896, 425.)

Long boiling impairs the purgative property of aloes; and the same effect is thought to be produced, to a certain extent, by the alkalies, which certainly qualify its operation and render it less apt to irritate the rectum. This decoction, therefore, is milder as a cathartic than aloes itself: it is also more tonic and cordial, from the presence of the myrrh, saffron, and cardamom, and derives antacid properties from the potassium carbonate. It is given as a gentle cathartic, tonic, and emmenagogue, and is especially useful in *dyspepsia*, *habitual constipation*, and atonic *amenorrhœa*. The dose is from one-half to two fluidounces (15–60 C.c.). The decoction should not be combined in prescription with acids, acidulous salts, or other bodies incompatible with the alkaline carbonate.

DECOCTUM CETRARIÆ. U. S. Decoction of Cetraria.

(DĒ-CŎC'TUM CĒ-TRĀ'RĬ-Æ.)

Decoction of Iceland Moss; Tisane (Décocté) de Lichen d'Islande, *Fr.;* Isländisch-Moos-Absud (Decoct), *G.*

"Cetraria, *fifty grammes* [or 1 ounce av., 334 grains; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Cover the Cetraria, in a suitable vessel, with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of cold Water, express after half an hour, and throw the liquid away. Then boil the Cetraria with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water for half an hour, strain, and add enough cold Water, through the strainer, to make the product, when cold, measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This decoction is stronger than the one official in 1870. At present 5 per cent. of Iceland moss is used in the preparation, instead of about 3 per cent. as formerly. The preparation was dropped from the Br. Ph. 1898. The directions of the U. S. P. 1850 were to boil *half an ounce* of the Moss with *a pint and a half* of Water down to a pint, and to strain with compression; and this process is preferable when the object is to extract not only the bitter principle, but also the whole of the demulcent and nutritive matter. As the bitter principle is dissolved along with the starch-like matter of the moss, this decoction has an unpleasant flavor; but the plan which has been proposed of first extracting the bitterness by maceration in water or a very weak solution of an alkaline carbonate, and afterwards preparing the decoction, is inadmissible, as

the peculiar virtues which distinguish the medicine from the ordinary demulcents are thus entirely lost. (See *Cetraria.*) A pint (473 C.c.) of the decoction may be taken during the day.*

* The following decoctions have been omitted in the recent revision of the Pharmacopœias, but, as they are still to a greater of less extent in use, require notice.

Decoctum Chimaphilæ. U. S. 1870. *Decoction of Pipsissewa.* "Take of Pipsissewa, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Pipsissewa in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870. This decoction is in every way inferior to the fluid extract. One pint (472 C.c.) of it may be given in the course of twenty-four hours.

Decoctum Cinchonæ Flavæ. U. S. 1870. *Decoction of Yellow Cinchona.* "Take of Yellow Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Yellow Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870.

Decoctum Cinchonæ Rubræ. U. S. 1870. *Decoction of Red Cinchona. Decoction of Red Bark.* "Take of Red Cinchona, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Red Cinchona in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870.

The decoctions of Cinchona have been very appropriately dropped from the Pharmacopœia. Although capable of impressing the system, they are very ineligible preparations. The dose of either decoction is two fluidounces (60 C.c.), to be repeated more or less frequently according to circumstances. Two drachms of orange peel, added to the decoction while still boiling hot, improve its flavor, and render it more acceptable to the stomach.

Decoctum Cornûs Floridæ. U. S. 1870. *Decoction of Dogwood.* "Take of Dogwood, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Dogwood in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870. This decoction has been proposed as a substitute for that of Peruvian bark; but, though possessed of analogous properties, it is much inferior in efficacy, and is not likely to be extensively employed so long as the Peruvian tonic is attainable. The dose is two fluidounces (60 C.c.).

Decoctum Dulcamaræ. U. S. 1870. *Decoction of Bittersweet.* "Take of Bittersweet, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the Bittersweet in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870. This is a good preparation of bittersweet if it is absolutely necessary to use an aqueous menstruum. Dose, from one to two fluidounces (30–60 C.c.).

Decoctum Quercûs Albæ. U. S. 1870. *Decoction of White-oak Bark.* "Take of White-oak Bark, bruised, *a troyounce;* Water *a sufficient quantity.* Boil the White-oak Bark in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870.

Decoctum Cinchonæ. Br. 1885. *Decoction of Cinchona.* "Take of Red Cinchona Bark, in No. 20 powder, *one ounce and a quarter* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel. Strain the decoction, when cold, and pour as much distilled water over the contents of the strainer as will make the strained product measure one pint [Imp. meas.]." *Br.* Dose, from one to two fluidounces (30–60 C.c.).

Decoctum Hordei. Br. 1885. *Decoction of Barley.* "Take of Pearl Barley *two ounces* [avoirdupois]; Distilled Water *one pint and a half* [Imperial measure]. Wash the Barley in cold water, and reject the washings; boil the washed Barley with the Distilled Water for twenty minutes, in a covered vessel, and strain. The product is about one pint." *Br.*

Barley water, as this decoction is usually called, is much employed as a nutritive drink in febrile and inflammatory complaints, and, from the total absence of irritating properties, is peculiarly adapted to cases in which the gastric or intestinal mucous membrane is inflamed. As the stomach of those for whom it is directed is often exceedingly delicate, it is important that the decoction should be properly made in accordance with the former official directions. The object of the washing with cold water is completely to remove any mustiness, or other disagreeable flavor, which the barley may have acquired from exposure. Dose, from one to four fluidounces (30–120 C.c.).

Decoctum Papaveris. Br. 1885. *Decoction of Poppy.* "Take of Poppy Capsules, bruised, *two ounces* [avoirdupois]; Distilled Water *a pint and a half* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction is used as an anodyne fomentation in painful tumors, and in superficial cutaneous inflammation or excoriation. It is recommended not to reject the seeds, as their oil, suspended in the water by the mucilage of the capsules, adds to the emollient virtues of the preparation.

Decoctum Pareiræ. Br. 1885. *Decoction of Pareira.* "Take of Pareira Root, in No. 20 powder, *one ounce and a quarter* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for fifteen minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This is apt to remain turbid after straining, but, if allowed to stand, gradually deposits insoluble matter, and then can be filtered perfectly clear. (*P. J. Tr.*, xiv. 491.) The dose is from one to two fluidounces (30–60 C.c.) three or four times a day.

Decoctum Quercus. Br. 1885. *Decoction of Oak Bark.* "Take of Oak Bark, bruised, *one ounce and a quarter* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction contains the tannin, bitter principle, and gallic acid of oak bark. It affords precipitates with the decoction of Peruvian bark and other substances containing vegetable alkaloids, with solution of gelatin, and with most metallic salts, particularly those of iron. Alkaline solutions diminish or destroy its astringency. Its uses have been already detailed. The dose is two fluidounces (60 C.c.), frequently repeated.

Decoctum Sarsæ. Br. 1885. *Decoction of Sarsaparilla.* "Take of Jamaica Sarsaparilla, cut transversely, *two ounces and a half* [avoirdupois]; Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest the Sarsaparilla in the Water for an hour; then boil for ten minutes in a covered vessel, cool, and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint [Imp. meas.]." *Br.*

An idea was long entertained that the virtues of sarsaparilla resided in its fecula, the extraction of which was, therefore, the main object of the decoction. Hence the long boiling formerly ordered by the London and Edinburgh Colleges. But this opinion is now admitted to have been erroneous. The activity of the root is believed to depend upon one or more acrid principles, soluble to a certain extent in water, cold or hot, and either volatilized or ren-

DECOCTUM GRANATI CORTICIS. Br. Decoction of Pomegranate Bark.

(DĘ-CŎC'TUM GRĄ-NĀ'TĪ CÖR'TĮ-CĬS.)

Decoctum Granati Radicis, *Br.* (1885), Decoctum Corticis Radicis Granati; Tisane (Décocté) d'Ecorce de la Racine de Grenadier, *Fr.;* Granatwurzel-Rinden-Absud, *G.*

"Pomegranate Bark, in No. 10 powder, 4 *ounces* (Imperial) or 200 grammes; Distilled Water, *a sufficient quantity.* Boil the Pomegranate Bark with *twenty-four fluid ounces* (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water in a suitable vessel for ten minutes; strain; pour enough Distilled Water over the contents of the strainer to made *one pint* (Imp. meas.) or one thousand cubic centimetres of the strained Decoction." *Br.*

This decoction has double the quantity of bark in the Br. Pharm. 1898 over the Br. Pharm. 1885, the quantity of root bark in the latter for one pint being two ounces.

For the uses and dose of this decoction, see *Granati Radicis Cortex.*

DECOCTUM HÆMATOXYLI. Br. Decoction of Logwood.

(DĘ-CŎC'TUM HÆ-MĄ-TŎX'Ỵ-LĪ—hē-mą-tŏk'sį-lī.)

Tisane (Décocté) de Bois de Campêche, *Fr.;* Blauholz-Absud, *G.*

"Logwood, in chips, 1 *ounce* (Imperial) or 50 grammes; Cinnamon Bark, bruised, 70 *grains* (Imp.) or 8 grammes; Distilled Water, *a sufficient quantity.* Boil the Logwood with *twenty-four fluid ounces* (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water in a suitable vessel for ten minutes, adding the Cinnamon Bark towards the end of the time; strain; pour enough Distilled Water over the contents of the strainer to make *one pint* (Imp. meas.) or one thousand cubic centimetres of the strained Decoction." *Br.*

We prefer the old U. S. formula, which ordered an ounce of the logwood to be boiled with two pints down to a pint, and doubt much whether the wood is exhausted by a boiling of ten or fifteen minutes. The cinnamon of the Br. formula is in general a very suitable addition, but there might be circumstances under which it would be better omitted; and in this case, as in others, any addition to the simple decoction might be left to the judgment of the prescriber.

This is an excellent astringent in *diarrhœas* of relaxation. Dose, for an adult, two fluidounces (60 C.c.); for a child about two years old, two or three fluidrachms (7·5–11·25 C.c.).

DECOCTUM SARSAPARILLÆ COMPOSITUM. U. S. Compound Decoction of Sarsaparilla.

(DĘ-CŎC'TUM SĂR-SĄ-PĄ-RĬL'LÆ CǪM-PŎŞ'Į-TŬM.)

Decoctum Sarsæ Compositum, *Br.* 1885; Tisane (Apozème) sudorifique, Décocté de Salsepareille composé, *Fr.;* Zusammengesetztes Sarsaparilla-Decoct, *G.*

"Sarsaparilla, cut and bruised, *one hundred grammes* [or 3 ounces av., 230 grains]; Sassafras, in No. 20 powder, *twenty grammes* [or 308 grains]; Guaiacum Wood, rasped, *twenty grammes* [or 308 grains]; Glycyrrhiza, bruised, *twenty grammes* [or 308 grains]; Mezereum, cut and bruised, *ten grammes* [or 154 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Boil the Sarsaparilla and Guaiacum

dered inert by chemical change, at the temperature of 100° C. (212° F.). This fact appears to be demonstrated by the experiments of Pope, Hancock, Soubeiran, Beral, and others. Soubeiran macerated one portion of bruised sarsaparilla in cold water for twenty-four hours; infused another portion in boiling water, and digested with a moderate heat for two hours; boiled a third portion bruised, and a fourth unbruised, in water for two hours; and in each instance used the same relative quantities. Testing these various preparations by the taste, he found the cold and hot infusions scarcely different in this respect, and both possessed of a stronger odor and more acrid taste than the decoctions, of which that prepared with the bruised root was the strongest. From these facts the inference is obvious, that the best method of imparting the virtues of sarsaparilla to water is either by cold or hot infusion. Digestion for some hours in water maintained at a temperature of 82·2° C. (180° F.), or somewhat less, in a covered vessel, has strong testimony in its favor. Percolation, if properly conducted, is a convenient and no doubt efficient mode of exhausting the root, so far as water will effect that object. Decoction is the worst method; and the longer it is continued the weaker will be the preparation. For these reasons the decoction of sarsaparilla is no longer official. Precipitates are produced by various substances with this decoction; but it has not been ascertained how far such substances interfere with its activity. Those which merely throw down the fecula do not injure the preparation. **Dose, from four to six fluidounces (120–180 C.c.).**

Decoctum Scoparii. Br. 1885. *Decoction of Broom.* "Take of Broom-tops, dried, *one ounce* [avoirdupois]: Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

This decoction is a very useful diuretic in *dropsy.* From half a pint to a pint (236–472 C.c.) may be taken during the day, in doses of from two to four fluidounces (60–120 C.c.).

Decoctum Taraxaci. Br. 1885. *Decoction of Dandelion.* "Take of Dried Dandelion Root, sliced and bruised, *one ounce* [avoirdupois]; Distilled Water *one pint* [Imperial measure]. Boil for ten minutes in a covered vessel, then strain, and pour as much distilled water over the contents of the strainer as will make the strained product measure a pint [Imp. meas.]." *Br.*

Dose, two fluidounces (60 C.c.) two or three times a day. (See *Taraxacum.*)

Wood for half an hour in a suitable vessel with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water. Then add the Sassafras, Glycyrrhiza, and Mezereum, cover the vessel well, and macerate for two hours. Finally strain, and add enough cold Water, through the strainer, to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The Br. Pharmacopœia (1898) no longer recognizes Compound Decoction of Sarsaparilla.*

This decoction is an imitation of the celebrated *Lisbon diet drink.* The sarsaparilla and mezereon are the active ingredients; the guaiacum wood imparting scarcely any of its virtues, and the sassafras and liquorice serving little other purpose than to communicate a pleasant flavor. An improvement was made in the U. S. formula of 1880 in directing the sassafras, glycyrrhiza, and mezereum to be added after the boiling of the ligneous drugs has been completed. Compound Decoction of Sarsaparilla now contains a little more sarsaparilla, sassafras, guaiacum wood, and glycyrrhiza than the U. S. formula of 1870, but nearly double the quantity of mezereum: as the latter has been believed by many to be the only active substance in this weak preparation, the increase in quantity was judicious. If prepared with good sarsaparilla, and with a due regard to the practical rules which may now be considered as established, the decoction may be used with advantage as a gentle diaphoretic and alterative in secondary syphilis, either alone, or as an adjuvant to a mercurial course; also in certain scrofulous and other depraved conditions of the system, in chronic rheumatism, and in various obstinate cutaneous affections. The dose is from four to six fluidounces (120–180 C.c.) three or four times a day. The patient during its use should wear flannel next the skin, and avoid unnecessary exposure to changes of temperature.†

DIGITALIS. U. S. (Br.) Digitalis. [Foxglove.]‡

(DĬG-Ĭ-TĀ'LĬS.)

"The leaves of Digitalis purpurea, Linné (nat. ord. Scrophularineæ), collected from plants of the second year's growth." *U. S.* "The dried leaves of Digitalis purpurea, Linn. Collected from plants commencing to flower." *Br.*

Digitalis Folia, *Br.,* Digitalis Leaf; Folia Digitalis, *P. G.;* Digitalis Leaves, Foxglove Leaves; Feuilles de Digitale pourprée (de grande Digitale), Digitale pourprée, Doigtier, *Fr.;* Purpurrother Fingerhut, Fingerhutkraut, *G.;* Digitale purpurea, *It.;* Dedalera, *Sp.*

* "Take of Jamaica Sarsaparilla, cut transversely, *two ounces and a half;* Sassafras Root, in chips, Guaiacum Wood turnings, Dried Liquorice Root, bruised, each *a quarter of an ounce;* Mezereon Bark *one-eighth of an ounce;* Boiling Distilled Water *one pint and a half* [Imperial measure]. Digest the solid ingredients in the Water for an hour; then boil for ten minutes in a covered vessel; cool and strain, pouring distilled water, if required, over the contents of the strainer, or otherwise making the strained product measure a pint [Imp. meas.]." *Br.* 1885. The ounce employed in this process is the avoirdupois ounce.

† The *Decoction of Zittmann* (Decoctum Zittmanni) is a preparation of Sarsaparilla much used in Germany for similar purposes with our compound decoction of sarsaparilla; and, as it has attracted some attention in this country as a remedy in obstinate ulcerative affections, we give the formula of the German Pharmacopœia, which is generally followed in its preparation. *Decoctum Sarsaparillæ Compositum Fortius,* P. G. [*Zittmann's Stronger Decoction.*] *Stärkeres Zittmann'sches Decoct.*—"Take of sarsaparilla root, cut, *one hundred parts;* pour upon it common water, *two thousand six hundred parts;* digest for twenty-four hours; then add of sugar powdered, alum powdered, each, *six parts,* and heat them in a covered vessel, in a steam bath, for three hours, stirring frequently. Towards the end of the boiling, add of anise bruised, fennel seed bruised, each, *four parts;* senna cut, *twenty-four parts;* liquorice root cut, *twelve parts.* Strain by expression, and set aside for a short time. The clear decanted liquid should be *two thousand five hundred parts.* When not otherwise directed, a colature of two thousand five hundred grammes is divided into eight portions.

"N.B.—When Decoctum Zittmanni is prescribed, it is prepared in a similar manner, except that to the sugar and alum are added of mild chloride of mercury, *four parts;* cinnabar (red sulphide of mercury), *one part,* enclosed in a linen bag." *P. G.*

Decoctum Sarsaparillæ Compositum Mitius, P. G. [*Zittmann's Milder Decoction.*] *Milderes Zittmann'sches Decoct.*—"Take the residue of the stronger decoction and sarsaparilla root, cut, *fifty parts;* pour upon them common water, *two thousand six hundred parts,* and expose to the heat of a steam bath for three hours in a covered vessel, stirring frequently. Towards the end of the operation add of lemon peel, cassia bark, small cardamoms, liquorice root, each, cut and bruised, *three parts.* Strain by expression, and set aside for a short time. The clear decanted liquid should be *two thousand five hundred parts.* When not otherwise directed, a colature of two thousand five hundred grammes is divided into eight portions." *P. G.* Mercury was detected by Wiggers in this decoction in very small proportion. It should not be prepared in metallic vessels, lest the mercurial in solution should be decomposed. The decoction may be drunk freely.

Decoctum Senegæ. U. S. 1870. *Decoction of Seneka.* "Take of Seneka, bruised, a *troyounce;* Water *a sufficient quantity.* Boil the Seneka in a pint of Water for fifteen minutes, strain, and add sufficient Water, through the strainer, to make the decoction measure a pint." *U. S.* 1870.

This is one of the decoctions in which experience has shown that long boiling impairs the activity of the medicine. It is customary to add to the seneka in decoction an equal weight of liquorice root, which serves to cover its taste and in some measure to obtund its acrimony. The virtues and practical application of seneka will be treated of under *Senega.* The dose of the decoction is about *two fluidounces* (60 C.c.).

‡ Foxglove is a corruption of Folksglove, Folk being an old English synonyme of Fairies.

Digitalis purpurea. Willd. *Sp. Plant.* iii. 383; Woodv. *Med. Bot.* p. 218, t. 78. The foxglove is a beautiful plant, with a biennial or perennial fibrous root, which in the first year sends forth large tufted leaves, and in the following summer a single erect, downy, and leafy stem, rising from two to five feet, and terminating in an elegant spike of purple flowers. The lower leaves are ovate, pointed, about eight inches in length and three in breadth, and stand upon short, winged footstalks; the upper are alternate, sparse, and lanceolate; both are obtusely serrate, and have wrinkled velvety surfaces, of which the upper is a fine deep green, the under paler and more downy. The flowers are numerous, and attached to the upper part of the stem by short peduncles, in such a manner as generally to hang down upon one side. At the base of each peduncle is a floral leaf, which is sessile, ovate, and pointed. The calyx is divided into five segments, of which the uppermost is narrower than the others. The corolla is monopetalous, bell-form, swelling on the lower side, irregularly divided at the margin into short obtuse lobes, and in shape and size not unlike the end of the finger of a glove, a circumstance which has suggested most of the names by which the plant is designated in different languages. Its mouth is guarded by long soft hairs. Externally, it is in general of a bright purple; internally, it is sprinkled with black spots upon a white ground. There is a variety with white flowers. The filaments are white, curved, and surmounted by large yellow anthers. The style is simple, and supports a bifid stigma. The seeds are numerous, very small, grayish brown, and contained in a pyramidal two-celled capsule.*

The foxglove grows wild in the temperate parts of Europe, where it flowers in the middle of summer. In this country it is cultivated both for ornament and for medical use. The leaves are the part generally employed. Much care is requisite in selecting, preparing, and preserving them, in order to insure their activity. They should be gathered in the second year, immediately before or during the period of inflorescence, and those only chosen which are full-grown and perfectly fresh (*Geiger*); but the observations of F. Schneider would lead to the conclusion that they are much stronger when not gathered before the latter part of summer or the beginning of autumn. (*A. J. P.*, 1870, p. 221.) It is said that those plants are preferable which grow spontaneously in elevated places exposed to the sun. (*Duncan.*) As the leafstalk and midrib are comparatively inactive, they may be rejected. Withering recommends that the leaves should be dried either in the sunshine, or by a gentle heat before the fire; and care should be taken to keep them separate while drying. Pereira states that a more common and, in his opinion, a preferable mode is to dry them in a basket in a dark place in a drying-stove. It is probably owing, in part, to the want of proper attention in preparing digitalis for the market that it is so often inefficient. The dried leaves should be kept in tin canisters, well closed so as to exclude light and moisture; or they may be pulverized, and the powder preserved in well-stopped and opaque bottles. As foxglove deteriorates by time, it should be frequently renewed, as often, if possible, as once a year. Its quality must be judged of by the degree in which it possesses the characteristic properties of color, smell, and especially taste. It is said to be sometimes adulterated; but if it be bought in leaf, there can be little difficulty, to one acquainted with the characters of the genuine leaves, in detecting the sophistication. German digitalis consists of the leaves of wild plants, whereas English digitalis is from cultivated plants. According to Joseph W. England, comparative experiments made in the Philadelphia Hospital have shown the English digitalis to be much more uniform and active than is the German drug. This may be because the English variety is more carefully freed from leafstalks, since Broeker found the parenchyma to yield five times as much digitalin as did the leafstalks.

Digitalis Leaf. Epidermis of the lower side, showing stomata and hairs.

The seeds contain more of the active principle than the leaves, are less apt to suffer in drying, and keep better, but are little used. So far as the relative strength of these two parts can be determined from that of their alcoholic extracts, it would appear, from the experiments of Prof. Hirtz, that the seeds are ten times stronger than the leaves. (See *A. J. P.*, xxxiii.)

Properties. Foxglove is without smell in the recent state, but acquires a faint narcotic odor when dried. The color of the dried leaf is a dull pale green, modified by the whitish down upon the under surface; that of the powder is a fine deep green. "From 10 to 30 Cm. long; ovate or ovate-oblong, narrowed into a petiole; crenate; dull green, densely and finely

* *Digitalis ambigua* contains, according to Paschkis, the same constituents as *D. purpurea* (*Apoth. Ztg.*, 1888.)

pubescent; wrinkled above; paler and reticulate beneath; midrib near the base broad; odor slight, somewhat tea-like; taste bitter, nauseous. An infusion prepared with 1 part of Digitalis and 10 parts of boiling water, and allowed to cool, has a peculiar odor, turns blue litmus paper red, and, upon the addition of a few drops of ferric chloride test-solution, acquires a darker tint, a brown precipitate appearing after a few hours. The infusion, diluted with 3 parts of water, becomes turbid on the addition of a few drops of tannic acid test-solution." *U. S.* "The transverse section exhibits a mesophyll free from crystals of calcium oxalate." *Br.* Digitalis yields its virtues both to water and to alcohol. It contains, besides active principles, a volatile oil, a fatty matter, a red coloring substance analogous to extractive, chlorophyll, albumen, starch, sugar, gum, lignin, and salts of potassa and lime, among which, according to Rein and Haase, is potassium superoxalate. M. Morin, of Geneva, discovered in the leaves two acids: one fixed, called *digitalic acid*, the other volatile and resembling valerianic acid, which he proposed to name *antirrhinic acid* (*P. J. Tr.*, vii. 294). J. W. England (*A. J. P.*, 1892, 361) found about 5 per cent. of fixed oil in digitalis leaves. Dr. Morries obtained a narcotic empyreumatic oil by the destructive distillation of the leaves.

Under the name of *digitalin** there have long been in commerce two distinct substances obtained from digitalis, both of them of the nature of extracts rather than of organic principles. The *French* digitalin was that originally prepared by Homolle. It is a whitish powder, of a neutral reaction, soluble in 2000 parts of cold and in 1000 parts of hot water. It is this digitalin which was formerly recognized by the U. S. and Br. Pharmacopœias. The so-called *German* digitalin is distinguished from the French by being, in great part or entirely, freely soluble in water.

In 1871, M. Nativelle received from the French Academy the prize of Orfila for the discovery of the active principle of digitalis. The method of preparation, as finally improved and modified by himself, and published in the *Journ. de Pharm.*, xx. 1874, p. 81, and also a process which has the advantage of being far shorter and more readily carried out, devised by M. Tanret (*Ibid.*, Oct. 1875), may be found on p. 1143, 14th ed., U. S. Dispensatory.

According to the researches of Schmiedeberg (*Pharm. Journ.*, (3) v. 741), confirmed by Kiliani (*Pharm. Journ.*, (3) xxii. 1061, and (4) i. 29), the seeds and leaves of digitalis purpurea contain a preponderating amount of a glucoside, *digitonin*. They contain in addition three other substances which possess the power of acting on the heart,—namely, crystallizable *digitoxin* and two amorphous glucosides, *digitalin* and *digitalein*. They also contain an inert crystallized body called *digitin*, $C_4H_8O_2$.

DIGITONIN forms fully one-half of the mixed glucosides from the digitalis seed and the principal portion of German "digitalin," from which it may be prepared by extraction with and crystallization from 85 per cent. alcohol. Digitonin softens at 225° C. and melts completely at 235° C. The crystals dissolve sparingly in cold water, more readily in hot, to an opalescent solution which froths on agitation. It cannot be crystallized from water. The aqueous solution

* *French digitalin* may be prepared according to the following process, which was formerly recommended by the British Pharmacopœia:

"Take of Digitalis Leaf, in coarse powder, *forty ounces* [avoirdupois]; Rectified Spirit, Distilled Water, Acetic Acid, Purified Animal Charcoal, Solution of Ammonia, Tannic Acid, Oxide of Lead in fine powder, Pure Ether, of each, *a sufficiency*. Digest the Digitalis with a gallon [Imperial measure] of the Spirit for twenty-four hours at a temperature of 120°; then put them into a percolator, and, when the tincture has ceased to drop, pour a gallon [Imp. meas.] of Spirit on the contents of the percolator, and allow it slowly to percolate through. Distil off the greater part of the Spirit from the tincture, and evaporate the remainder over a water-bath until the whole of the alcohol has been dissipated. Mix the residual extract with five [fluid]ounces of Distilled Water to which half an ounce [avoird.] of Acetic Acid has been previously added, and digest the solution thus formed with a quarter of an ounce of Purified Animal Charcoal; then filter, and dilute the filtrate with Distilled Water until it measures a pint [Imp. meas.]. Add Solution of Ammonia nearly to neutralization, and afterwards add one hundred and sixty grains of Tannic Acid dissolved in three [fluid]ounces of Distilled Water. Wash the precipitate that will be formed with a little Distilled Water; mix it with a small quantity of the Spirit and a quarter of an ounce of the Oxide of Lead, and rub them together in a mortar. Place the mixture in a flask, and add to it four [fluid]ounces of the Spirit; raise the temperature to 160°, and keep it at this heat for about an hour. Then add a quarter of an ounce of Purified Animal Charcoal; put it on a filter, and from the filtrate carefully drive off the Spirit by the heat of a water-bath. Lastly, wash the residue repeatedly with Pure Ether." According to the method of Walz (Husemann, *Die Pflanzenstoffe*, p. 900), *German digitalin* is prepared by extracting under pressure one part of digitalis with eight parts of alcohol, evaporating, digesting the residue with successive portions of water so long as they acquire a bitter taste, uniting the liquids, and treating them with litharge and lead acetate until a portion filtered for testing is no longer precipitated by lead acetate. Sulphuric acid is added to the filtrate to precipitate the lead, and, after filtration, neutralized with ammonia, and the liquid precipitated by tannic acid. The precipitate, having been well washed and pressed, is rubbed up with freshly precipitated lead oxide, the mass boiled with alcohol, and, after the lead has been separated by precipitation with sulphuric acid, and most of the alcohol distilled off, the residue is allowed to slowly evaporate, the crude digitalin being left behind.

is lævo-rotatory ($[a]_D = -49{\cdot}25°$ C.), and is precipitated by tannin, ammoniacal lead acetate, and baryta water. Digitonin is only slightly soluble in absolute alcohol, and still less so in ether, chloroform, or petroleum spirit. It forms a crystalline compound with amyl alcohol. According to Kiliani, digitonin has the formula $C_{27}H_{46}O_{14} + 5H_2O$, and when boiled with strong alcohol and hydrochloric acid splits up into *dextrose*, *galactose*, and *digitogenin*, the last body separating in warty masses on cooling.

Digitoxin is characterized by its free solubility in alcohol and chloroform, slight solubility in ether, and insolubility in petroleum spirit. It crystallizes from alcohol in pearly scales or needles which melt at 240° C. It is quite insoluble in water, to which it does not impart even a bitter taste. Warmed with strong hydrochloric acid, it gives a yellow or greenish coloration, which is one of the reactions ascribed to the "digitaline crystallisé" of the French Codex. Schmiedeberg states that it is not a glucoside, but Kiliani asserts that upon heating its alcoholic solution with hydrochloric acid it splits up into *digitoxigenin* and a glucose *digitoxose*. Kiliani writes the reaction for this, $C_{31}H_{50}O_{10} = C_{22}H_{32}O_4 + C_9H_{18}O_6$. Digitoxin is found mainly in the leaves (Kiliani stating that it is not found in the seeds at all), but Keller (*P. J. Tr.*, July 24, 1897) finds it also in the seeds in smaller amount. It is the most poisonous of the constituents of digitalis.

Digitalin (*Digitalinum verum* of Kiliani) forms a white amorphous powder or soft white grains which remain unchanged when heated to 200° C., at 210° C. begin to aggregate, and towards 217° C. melt, becoming yellow. When treated with water the particles of digitalin swell up and dissolve slightly, giving a solution which foams strongly on agitation. It is dissolved sparingly by cold proof spirit (1–100), but in considerable amount by hot rectified spirit or absolute alcohol. When a minimum of alcohol is used, the solution on cooling becomes almost solid from the separation of a thick magma of granules, which are, however, destitute of crystalline structure. This peculiar behavior affords a valuable means of testing its purity, as only a small percentage of the other glucosides with the digitalin prevents the formation of the granules. The minutest admixture of amorphous glucosides also rapidly causes an intense yellow coloration. Digitalin is very sparingly soluble in ether or chloroform. When digitalin is heated with dilute hydrochloric acid, an insoluble resinous substance almost immediately separates out; Schmiedeberg termed this *digitaliresin*. By operating in alcoholic solution, Kiliani avoids the separation of resin, and finds that digitalin splits up as a glucoside into *digitaligenin*, *glucose*, and *digitalose*, according to the reaction $C_{29}H_{48}O_{12} + H_2O = C_{16}H_{22}O_2 + C_6H_{12}O_6 + C_7H_{14}O_5$. Kiliani found that the commercial *digitalinum purum* contained but 5·5 per cent. of true digitalin.

Digitalein is considered to be a distinct glucoside by Schmiedeberg, but Kiliani, who worked over it later, regards its independent existence as questionable.

Digitin of Schmiedeberg is also considered by Kiliani to be simply digitonin.

The above résumé of our present knowledge clearly shows that the chemistry of digitalis cannot be considered as settled; but it also clearly shows that no digitalin completely represents digitalis. Moreover, the digitalin of commerce varies greatly. (See *Archiv d. Pharm.*, 1895, 299; also 1895, 698.) For methods of testing digitalin, see *Drug. Bull.*, 1893, 108.

Medical Properties and Uses. Experiments upon the lower animals, confirmed by clinical observation, have shown that digitalis acts primarily and with most force upon the circulation, producing a great rise in the arterial pressure, followed, in poisoning, by a no less marked fall, which, however, does not take place at all after moderate doses. The increased blood force is due partly to increased cardiac action and partly to vaso-motor spasm. Upon the heart digitalis acts by stimulating the peripheral ends of the inhibitory nerves and also the cardiac muscle. By the first influence it produces prolongation of the diastole; by the second, an increased putting forth of power in the systole. The work done by the heart under the influence of the drug is much beyond normal. After a toxic dose the systolic irritation overbalances the diastolic stimulation, and the pulse becomes dicrotic, because the diastole is interrupted by an abortive systole. Finally, the apex of the heart never dilates, diastole is continually interrupted by systolic contractions, and the aortic system remains empty, because the left ventricle never relaxes sufficiently to receive blood. The final cessation of the heart's action is not due to paralysis, but to spasm, the heart ceasing not in diastole, but in systole.

This résumé of our knowledge of the physiological action clearly shadows forth the proper use of the drug. It is indicated when the heart is weak, not absolutely, but relatively weak, or, in other words, when the work required of the heart is greater than its power. When digitalis is administered in ordinary doses, it produces at first no distinct effect; but if the

dose be repeated, after a time the pulse becomes less frequent. The pauses between the beats are longer than before, and the individual beat is longer, fuller, and stronger, indicating that the heart is acting with more force than normal. When the reduction of the pulse-rate has commenced, it is apt to continue for some days, and even to increase for a time, although the use of the remedy be intermitted, slowness and permanency of action being characteristic of digitalis. In some cases, gastric disturbance, and even nausea, vomiting, and diarrhœa, are produced by therapeutic doses of the drug. If sufficient of the remedy have been taken into the system, the pulse may fall to 35 or 40 a minute, still preserving the peculiarity of a distinctly dicrotic beat. Now a very peculiar phenomenon may often be witnessed. Whilst the patient is quiet in the horizontal position the pulse is very slow and strong, but when he rises to his feet it becomes at once rapid, irregular, small, and feeble, and even hobbling. During the milder operation of digitalis there may be some sense of cerebral disturbance, brow-tightness, and even a confusion of thought and giddiness. After toxic doses the symptoms are severe; a feeble, scarcely perceptible pulse, nausea and vomiting, stupor or delirium, cold sweats, extreme prostration of strength, hiccough, convulsions, and syncope have in several cases preceded the fatal issue.

The dilated heart is of course a weak heart, and simple cardiac dilatation is one of the strongest indications for the use of digitalis, whilst cardiac hypertrophy is a contra-indication. It must not be forgotten, however, that in valvular disease of the heart, the heart, although stronger than normal, may be relatively weak, because the leakage at the diseased valve requires more power to overcome its effect than even the increased strength of the cardiac muscle is able for. Hypertrophy exists, but is not sufficient to be compensatory. In all forms of valvular lesion, when the hypertrophy is not compensatory, digitalis is very useful. It is also to be employed (hypodermically) in sudden cardiac exhaustion from any cause. Dropsy is very frequently the result of a general venous repletion, which also interferes with the function of the kidneys. Under these circumstances digitalis is a favorite remedy, and also acts as a decided diuretic. In these cases the result is in greater or less part due to the improvement of the circulation; but the drug has some tendency, even in health, to provoke diuresis. It is especially when it fails to do this that the so-called cumulative action is apt to be witnessed. After giving the drug for a long time without apparent effect, suddenly symptoms so severe as to be toxic are manifested. In aneurism, or when from any reason the coats of the vessels are thin or fragile, digitalis is contra-indicated. We have seen a dilated aorta ruptured by the powerful blood-current produced by the drug.

Externally applied, digitalis sometimes acts speedily and powerfully as a diuretic, and has proved useful in dropsy. For this purpose the fresh leaves bruised, or the dried leaves made into a poultice, or flannels wet with the tincture, may be applied to the abdomen and on the inside of the thighs. Ch. Hoffman has shown by experiments on himself that the active matter of digitalis is capable of being absorbed through the skin, and that its effects on the system may be obtained by means of baths.* A case is recorded in which a cataplasm of the leaves applied to the abdomen for the relief of obstinate and dangerous suppression of urine, and repeated in six hours, brought on excessive diuresis, with a discharge amounting to probably 8 gallons in less than 24 hours, producing fatal exhaustion. (*Med. Times and Gaz.*, Jan. 1868.)

Digitalis is administered in substance. The dose of the powder is one grain (0·065 Gm.), repeated twice or three times a day, and gradually increased till some effect is produced upon the head, stomach, pulse, or kidneys, when it should be omitted or reduced. The question as to which of the preparations of digitalis is preferable is a very important one. All the active principles are soluble in alcohol; the tincture (*Tinctura Digitalis*), therefore, fully represents the crude drug. According to Kobert, in the making of the fluid extract digitoxin is precipitated as an insoluble powder. If this be correct, the fluid extract does not as fully represent the crude drug as does the tincture. It is, however, very possible, indeed probable, that digitoxin should be precipitated in one method of making a fluid extract and not in another, so that it cannot be considered demonstrated that the fluid extract, U. S. P., contains no digitoxin. As digitoxin is not soluble in water, it would seem, *a priori*, probable that it and the other constituents of the so-called French or insoluble digitalin would be left behind in making an

* M. Hoffman, during a period of 44 days, took 16 baths prepared with 300 liters of water and 250 grammes of digitalis leaves. After the third bath he began to feel the effects of the medicine,—namely, a peculiar uneasiness, and a reduction of the pulse 4 or 5 pulsations per minute; and this condition persisted several hours. At the eighth bath the uneasiness was increased, and the pulse decreased from 68 to 51. After the sixteenth bath the pulse fell to 48. (*Journ. de Pharm. et de Chim.*, Juillet, 1867, p. 37.)

infusion, but certainly the infusion of digitalis is an active preparation and is preferred by many practitioners. It is possible that the superiority claimed by some clinicians for the infusion, which we have elsewhere otherwise explained (see page 733), is in fact due to the absence from it of active substances which are present both in the crude digitalis and in the tincture. A careful chemical physiological investigation of the relative activities of the preparations of digitalis seems to us urgently needed, but the probabilities are that all the official preparations are active when they have been carefully made from well-selected leaves.

The subject of the therapeutic activity and value of the different non-official preparations of digitalis is one of great difficulty, and at present of doubt. In these paragraphs we propose to consider only the commercial products or educts of digitalis which are for sale in the market. These commercial preparations are of two characters, the so called digitalins—which should be looked upon as purified or rather as partial extracts of digitalis—and certain alleged active principles.

As already stated (p. 484), there are two digitalins; of these *Digitalinum gallicum*, or French digitalin, official in the French and Belgian Pharmacopœias, is almost insoluble in water, and is said to consist largely of a glucoside allied to digitoxin. (See *P. J. Tr.*, 1898, 506.) The dose of the commercial article is put down at 0·00025 Gm., rapidly increased to 0·0015 Gm. per day; the maximum daily dose being 0·002 Gm. The granules of Homolle, which are commonly used in Europe, each contain a milligramme, or about the seventieth of a grain; probably equivalent, on the average, to a grain and a half of digitalis of medium strength. One of these globules is usually given as a commencing dose. Forty of them taken with a view to suicide, though followed by copious vomiting, produced the most alarming prostration, with a pulse weak, from 46 to 48 in a minute, intermittent, and at times scarcely perceptible. The patient, however, ultimately recovered. (*Ann. de Thérap.*, 1858, 103.)

Digitalinum germanicum, digitalin of the German Pharmacopœia, is soluble in water and alcohol but almost insoluble in chloroform; it is believed to be a mixture of digitalein, crystallized digitalin, digitonin, and digitalin of Kiliani. German digitalin may be used either by the mouth or hypodermically; the dose usually given is from 0·001 to 0·002 Gm., repeated twice or three times a day, increased if necessary; the maximum dose being 0·004 Gm., or the daily dose 0·02 Gm. It is contended by Dr. Henry Beates that these doses are absolutely inadequate, and he asserts as the result of much experience that the proper adult dose of the pure German digitalin is one-tenth of a grain, whilst the maximum dose is one-half a grain; also that these doses will be followed by definite and positive results and are entirely safe and free from unpleasant effects, excepting that occasionally the larger dose (one-third to one-half a grain) will cause some gastric disturbance, which is readily overcome by the use of bismuth and other proper remedies. He narrates cases in which four consecutive half-grain doses, administered at intervals of two hours, brought great relief. We are informed by Merck & Co. that in the manufacture of German digitalin the average yield is from 4 to 5 per cent. On this basis, if German digitalin did nearly represent digitalis, it would be from twenty to twenty-five times as strong, so that four-tenths of a grain of it would stand for eight grains of digitalis, or about seventy minims of the tincture. Unfortunately, it is plain that German digitalin does not completely represent digitalis; it is probable that it contains altered principles which do not exist in digitalis, and it is more than probable that commercial German digitalin varies greatly, according as it has been made by this or that manufacturer. It does not seem to be an eligible preparation, and if the practitioner uses it, he should employ habitually the make of one chemist with which he is practically familiar. We have been unable to find that it has any advantage over the official preparations, except that it is capable of being given in capsules, and is therefore less offensive to the palate and stomach. As a hypodermic agent in a limited trial it has so far proved to be as irritant as is the tincture of digitalis.

The statements in regard to the therapeutic activity of the various commercial products claiming to be pure active principles of digitalis vary greatly; moreover, the exact nature of the commercial alleged active principles is always doubtful; so that, if the practitioner use these substances at all, their employment should be looked upon as experimental.

Digitalinum crystallatum or *digitin* is commonly affirmed to be physiologically inactive, though Laffon asserts that it is as powerful as digitoxin.

Digitonin is asserted by authorities to be similar in its physiological action to saponin, which has, on the other hand apparently been demonstrated to be the physiological antagonist of

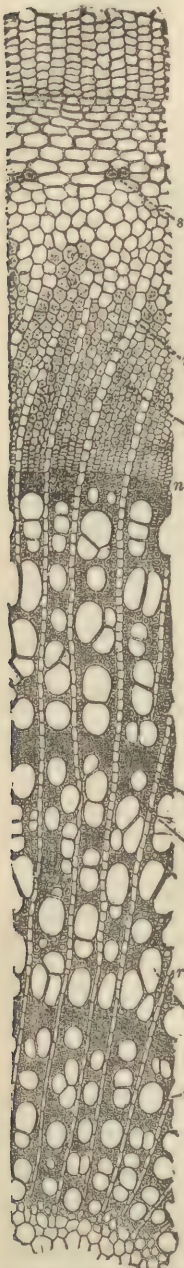
digitalis. It is evident, therefore, that digitonin, so far as our present knowledge is concerned, cannot be used as the representative of digitalis.

Of *digitalein*, it is asserted that when given in doses of from 0·001 to 0.002 Gm., two to four times a day, it acts as a heart tonic and diuretic similarly to digitalis. According to Merck & Co., the average yield of digitalein is 1 per cent., which would make the dose contained in one grain of digitalis the one-hundredth of a grain. It, however, represents at best such a small fraction of the activities of digitalis that a much larger dose would seem to be required. In this case the dose given by authorities evidently is below that which by calculation would appear to be safe. It is not probable, however, that digitalein nearly represents digitalis.

Of all these active principles, *crystallized digitoxin* is probably the most influential for good. Wenzel affirms that it acts more quickly and favorably in cardiac disease than does the infusion of digitalis, a conclusion which is practically confirmed by Potain, Pottiez, Starck, Masius, Corin, and others; whilst Kiliani (*Archiv d. Pharm.*, 1892–1896) alleges that it is the only important constituent of digitalis,—a conclusion, however, which seems to be gainsaid by the fact that digitoxin is insoluble in water, and therefore cannot exist in the infusion of digitalis unless it is made soluble by the presence in the digitalis leaf of digitalic or antirrhinic acid. The difficulty of the situation is shown by the fact that the same authority in one publication asserts that digitoxin is the most active of the digitalis preparations, and a complete substitute for digitalis; and in another publication affirms that the German digitalin is the most complete non-official representative of the drug, although it does not contain digitoxin. Merck & Co. inform us that the average yield of crystallized digitoxin is about four-tenths of one per cent.; supposing that digitoxin were the only active principle in digitalis, the dose of digitoxin equivalent to digitalis would be from one-two-hundred-and-fiftieth to one-two-hundredth of a grain (0·00025 to 0·00032 Gm.), which is practically the dose of digitoxin usually given in the books. As, however, digitoxin is not the only active principle of the digitalis, it would appear that its equivalent dose should be larger than that named.

The action of digitoxin appears to be very slow under any circumstances. Pottiez prefers exhibiting it by enemata, stating that in this way the vomiting which it often produces when ingested may be avoided. Wenzel also prefers administration by the rectum, using 15 Gm. of the following solution—digitoxin, ·01 Gm.; alcohol, 10 Gm.; water to make 200 Gm.—in 100 Gm. of lukewarm water, at first thrice, then twice, and lastly once daily. The single dose thus given was ·00075 Gm. digitoxin. In two cases only was an unpleasant result noted,—namely, vomiting,—and this soon ceased. When there is no haste, digitoxin may be given in granules. It is stated that under any circumstances its action is developed with extreme slowness, and it seems possible that it may be reprecipitated in the alimentary canal from its solution and accumulate in mass, to be absorbed subsequently and possibly produce unexpected effects; indeed, the fact naturally suggests itself that in some such way the cumulative action of the official preparations of digitalis may be accounted for. Corin affirms (*Les Nouveaux Remèdes*, 1895, 200) that the addition of water, or physiological fluid, or serum, whilst it will precipitate alcoholic solutions of 20 per cent. strength of digitoxin, will not affect a solution made in accordance with the following formula: Digitoxin, 2 to 3 milligrammes; Chloroform, 0·6 C.c.; Alcohol (90 per cent.), 12 C.c.; Water, a sufficient quantity to make 150 Gm. To be taken in three doses.

DULCAMARA. U. S. Dulcamara. [Bittersweet.]



(DŬL-CĄ-MĀ′RĄ.)

"The young branches of Solanum Dulcamara, Linné (nat. ord. Solanaceæ)." *U. S.*

Stipites Dulcamaræ, *P. G.;* Tiges de Douce-amère (de Nevrelle grimpante), Douce-amère, *Fr.;* Bittersüss, Bittersüss-Stengel, Alpranken, *G.;* Dulcamara, *It., Sp.*

This genus includes numerous species, of which several have been used in medicine. Besides *S. dulcamara*, which is the only official species, a few others merit notice. 1. *Solanum nigrum*, the *common garden* or *black nightshade*, is an annual plant from one to two feet high, with an unarmed herbaceous stem, ovate, angular-dentate leaves, and white or pale violet flowers, arranged in peduncled nodding umbel-like racemes, and followed by clusters of spherical black berries, about the size of peas. There are numerous varieties of this species, one of which is a native of the United States. The leaves are the part employed. They are said to produce diaphoresis, sometimes diuresis and moderate purging, and in large doses nausea and giddiness. As a medicine they have been used in cancerous, scrofulous, and scorbutic diseases, and other painful ulcerous affections, being given internally, and applied at the same time to the parts affected in the form of poultice, ointment, or decoction. A grain of the

dried leaves may be given every night, and gradually increased to ten or twelve grains, or till some sensible effect is experienced. The medicine, however, is scarcely used at present. By some persons the poisonous properties ascribed to the common nightshade are doubted. M. Dunal, of Montpellier, states, as the result of numerous experiments, that the berries are not poisonous to man or the inferior animals; and the leaves are said to be consumed in large quantities in the Isles of France and Bourbon as food, having been previously boiled in water. In the latter case the active principle of the plant must have been extracted by decoction. 2. The leaves, stalks, and unripe berries of *Solanum tuberosum*, or the *common potato*, are asserted to be narcotic; and an extract prepared from the leaves has been employed in cough and spasmodic affections, in which it is said to act like opium. (*Geiger.*) Dr. Latham, of London, found the extract to produce favorable effects in protracted *cough*, *chronic rheumatism*, *angina pectoris*, *cancer* of the uterus, etc. On the other hand, Dr. Worsham, of Philadelphia, found the extract, in the quantity of nearly one hundred grains, to cause no sensible effect. (*Phila. Journ. of the Med. and Phys. Sciences*, vi. 22.) We can reconcile these opposite statements only upon the supposition that the properties of the plant vary with the season, or with the place and circumstances of culture. Dr. Julius Otto found *solanine* in the germs of the potato. He was induced to make the investigation by observing that cattle were destroyed by feeding on the residue of germinating potatoes used for the manufacture of brandy. A case of death in a girl of fourteen, from eating the unripe fruit of the potato, is recorded in the *British Med. Journ.* for Sept. 3, 1859. The prominent symptoms were partial stupor, speechlessness, jactitation, hurried breathing, lividness of the skin, cold sweats, very frequent and feeble pulse, and a constant spitting through the closed teeth of viscid frothy phlegm. Death occurred on the second day. C. Haaf has found the same alkaloid in old potatoes which had begun to germinate, in the proportion of 0·16 in 500 parts; and in very young potatoes, deprived of their coating, precisely the same quantity. Fully ripe potatoes, which had not begun to sprout, gave a negative result. (*Neues Repert. für Pharm.*, 1864, p. 559.) 3. The well-known *tomato*, so much used as a vegetable at the table, and so advantageous through its nutritive, laxative, and antiscorbutic properties, is the fruit of a species of Solanum, denominated *S. lycopersicum*. The juice of the fruit is free from solanine, but contains several acids. Mr. T. D. McElhenie demonstrated the presence of citric, malic, and oxalic acids. (See *A. J. P.*, 1872, p. 198.) The seeds probably contain the alkaloid, as their alcoholic extract has a bitter, pungent taste. (See *A. J. P.*, xxxiv. 519.) Solanine has been obtained from the leaves and herbaceous part of the plant generally, by Mr. Geo. W. Kennedy. (*P. J. Tr.*, 1873, p. 606.) An infusion of the leaves is strongly recommended by M. Stanislaus Martin as a diuretic. (*Am. Journ. Med. Sci.*, 1873, 246.) 4. Several instances of poisoning are on record from the fruit of *S. pseudocapsicum*, or *Jerusalem cherry*, which, from its resemblance to the common cherry, is liable to be eaten by children. 5. In the *Edin. Med. Journ.* (1867, 398) several cases are recorded by Dr. Manners, of Jamaica, W. I., of poisoning by the *susumber berries*, of which one proved fatal, and several others recovered, probably in consequence of the early evacuation of the stomach by a mustard emetic. The symptoms recorded were anxious countenance, dilated pupil, cold skin, and difficult articulation. The fatal case was not seen by Dr. Manners till after death. The susumber berries are the fruit of a Solanum, denominated by Lunnan, in his "Hortus Jamaicensis," *S. bacciferum*, of which there appear to be two varieties, one relatively innocent, as its fruit is habitually used by the natives, the other poisonous, as would be inferred from the cases here noticed. 6. The *Solanum paniculatum*, called *jerubeba* in Brazil, is said to be largely used in South America in affections of the liver and spleen, catarrh of the bladder, anæmia, and amenorrhœa. The leaves, fruit, and root are

Section of Dulcamara. *r*, medullary rays; *sp*, ducts; *x*, woody tissues; *n*, cambium layer; *q*, bast-tissue; *s*, bast-cells.

employed, externally in the form of a plaster, internally in the form of syrup, wine, and extract. (*London Lancet*, 1866, 158.) *Solanum jacquinii* Willd. is used in India as a diaphoretic and expectorant. *Solanum aculeatissimum* is indigenous to Brazil; the fruit yields traces of solanine.

Solanum dulcamara. Willd. *Sp. Plant.* i. 1028; Woodv. *Med. Bot.* p. 237, t. 84; Bigelow, *Am. Med. Bot.* i. 169. The *bittersweet* or *woody nightshade* is a climbing shrub, with a slender, roundish, branching, woody stem, which, in favorable situations, rises six or eight feet in height. The leaves are alternate, petiolate, ovate, pointed, veined, soft, smooth, and of a dull green color. Many near the top of the stem are furnished with lateral projections at their base, giving them a hastate form. Some have the projection only on one side. Most of them are quite entire, some cordate at the base. The flowers are disposed in elegant clusters, somewhat analogous to cymes, and standing opposite to the leaves. The calyx is very small, purplish, and divided into five blunt, persistent segments. The corolla is wheel-shaped, with five pointed, reflected segments, which are of a violet-blue color, with a darker purple vein running longitudinally through their centre, and two shining greenish spots at the base of each. The filaments are very short, and support large, erect, lemon-yellow anthers, which cohere in the form of a cone around the style. The berries are of an oval shape and a bright scarlet color, and continue to hang in beautiful bunches after the leaves have fallen. This plant is common to Europe and North America. In the United States it extends from New England to Ohio, and is in bloom from June to August. The root and stalk have medicinal properties, though the latter only is official. A case, however, of death caused by the use of the berries by a child has been recorded. (See *P. J. Tr.*, 1861, p. 436.) Bittersweet should be gathered in autumn, after the fall of the leaf; and the extreme twigs should be selected. That grown in high and dry situations is said to be the best.

The dried twigs, as brought to the shops, are of various lengths, cylindrical, about as thick as a goose-quill, externally wrinkled, and of a grayish-ash color, consisting of a thin bark, an interior ligneous portion, and a central pith. They are inodorous, though the stalk in the recent state emits, when bruised, a peculiar, rather nauseous smell. Their taste, which is at first bitter and afterwards sweetish, has given origin to the name of the plant. "About 5 Mm., or less, thick, cylindrical, somewhat angular, longitudinally striate, more or less warty, usually hollow in the centre, cut into short sections. The thin bark is externally pale greenish, or light greenish-brown, marked with alternate leaf-scars, and internally green; the greenish or yellowish wood forms one or two concentric rings. Odor slight; taste bitter, afterwards sweet." *U. S.* Boiling water extracts all their virtues. These are supposed to depend, at least in part, upon an alkaloid called *solanine* or *solania*, which was originally discovered by M. Desfosses, of Besançon, in the berries of *Solanum nigrum*.* Winckler (1841) first observed that the alka-

* *Solanine* is most conveniently obtained from the sprouts of the common potato, by Wackenroder's process, which may be found detailed in the 16th edition of the U. S. Dispensatory. Its formula is variously given by various authorities: according to Delffs, it is $C_{40}H_{32}O_{14}$; according to Kletzinsky, it is $C_{42}H_{55}NO_{14}$; according to Zwenger and Kind, it is $C_{42}H_{75}NO_{15}$; according to R. Firbas, it is $C_{52}H_{93}NO_{18}$; and Hilger states that it is $C_{42}H_{87}NO_{15}$. Adrian asserts that it is a glucoside, and by heating with sulphuric or chlorhydric acid it breaks up into glucose and a second base, *solanidine*. This was confirmed by Zwenger and Kind, who give to solanidine the formula $C_{26}H_{41}NO_2$. The salts which solanine forms with acids are mostly amorphous in character. The oxalate, chromate, and phosphate form crystalline crusts. The acid sulphate is said to be very stable, and is not decomposed by water even on heating, in contradistinction to the neutral salt. It is amorphous and very bitter. The physiological action of solanine has been studied by several investigators, with not altogether concordant results. Geneuil (*Bull. de Thérap.*, tome iii.) finds that it has a depressing influence upon the medulla, spinal cord, and both motor and sensory nerve-trunks. In an elaborate investigation, Max Perles (*Arch. f. Exper. Path. u. Pharm.*, Leipzig, 1889, xxvi.) has determined that solanine acts as a powerful poison upon all forms of living protoplasm. When mixed with the blood outside of the body it causes rapid coagulation with alteration of the blood-corpuscles. In the frog it produces a centric paralysis, with later paralysis of the heart. When injected intravenously it caused in mammals violent dyspnœa, with cramp, arrest of respiration, and the presence of thrombi in the blood-vessels. Toxic doses given by the mouth produce excitement, with tremors, fibrillary contractions, cramp followed by central paralysis, collapse, and death in deep coma, preceded by a fall of temperature which is so great as to be almost characteristic. Vomiting and diarrhœa were frequently observed, and after death inflammation of the gastro-intestinal mucous membranes, and also a parenchymatous and even hemorrhagic nephritis. During life the urine was albuminous, containing casts, and not rarely was dark red from hæmoglobin, or sometimes meta-hæmoglobin. According to Capparoni, minute doses of solanine, whilst diminishing the rapidity of the heart's action, increase the arterial pressure.

In the researches of Max Perles, the action of *solanidine* was very similar to that of solanine, the chief difference between the two being that solanine is a violent local irritant, whilst solanidine seems free from local irritant properties. The two poisons are stated to belong physiologically to the sapotoxine group.

Solanine has been used by Geneuil, Capparoni, Vulpian, and others with asserted good results in *asthma*, to relieve the *cough* of *bronchitis*, to quiet the irritation of *cystitis* in the old, and for the relief of *gastralgia*, *pruritus*, *sciatica*, and other neuralgic or rheumatic pains. Capparoni (*Bull. Gén. de Thérap.*, May, 1888) affirms that it is an excellent analgesic, calming *ataxic* pains, and that it is even capable of controlling the *tremors* of lateral *sclerosis*.

Solanine has, however, been tried by various clinicians without results favorable to its use in practical medicine. (Consult *B. & F. Med.-Chir. Rev.*, July, 1854, Am. ed., p. 189; *Arch. Gén. de Méd.*, Mars, 1859, p. 360; *Bull. Gén.*

loid of dulcamara stems can be obtained only in an amorphous state, and that it behaves to platinic and mercuric chlorides differently from the solanine of potatoes. Moitessier (1856) confirmed this observation, and obtained only amorphous salts of the solanine of bittersweet. Wittstein (1852) supposed another alkaloid, *dulcamarine*, to be present, but Geissler (1875) showed that this substance was a glucoside, and not an alkaloid, yielding on decomposition with dilute acids *dulcamaretin* and sugar. He assigned the formula $C_{22}H_{34}O_{10}$ to dulcamarine, and $C_{16}H_{26}O_6$ to dulcamaretin. (Flückiger, *Pharmacographia*, 2d ed., p. 451.) *Solanine* is in the form of a white opaque powder, or of delicate acicular crystals, somewhat like those of quinine sulphate, though finer and shorter. It is inodorous, of a bitter taste, fusible at from 235°–240° F., decomposing at a slightly higher temperature with an odor of caramel, a sublimate of solanidine forming. It is scarcely soluble in water, soluble in alcohol and ether, and capable of neutralizing the acids. It is distinguished by the deep brown or brownish-yellow color which iodine imparts to its solution, and by its reaction with sulphuric acid, which becomes first reddish yellow, then purplish violet, then brown, and, lastly, again colorless, with the deposition of a brown powder.* In regard to the physiological action of solanine the statements of the earlier and later observers are at such variance that they must have worked with different substances. J. Otto found one grain sufficient to kill a rabbit in six hours; whilst Dr. Gaignard found five grains insufficient. The symptoms produced by solanine are said to be spasmodic labored respiration, dilatation of the pupils, intense dyspnœa, convulsions, paraplegia. Besides solanine, the stalks of *S. dulcamara* contain, according to Pfaff, a peculiar principle to which he gave the name of *picroglycion*, indicative of the taste at once bitter and sweet which it is said to possess. This was obtained by Blitz, in the following manner. The watery extract was treated with alcohol, the tincture evaporated, the residue dissolved in water, the solution precipitated with lead subacetate, the excess of this salt decomposed by hydrogen sulphide, the liquor then evaporated to dryness, and the residue treated with acetic ether, which yielded the principle in small isolated crystals by spontaneous evaporation. Pfaff found also in dulcamara a vegeto-animal substance, gummy extractive, gluten, green wax, resin, benzoic acid, starch, lignin, and various salts of lime.

Medical Properties and Uses. Dulcamara possesses feeble narcotic properties, with the power of increasing the secretions, particularly those of the kidneys and skin. Dr. Geo. B. Wood observed, when the system was under its influence, a dark purplish color of the face and hands, and at the same time considerable languor of the circulation. In overdoses it produces nausea, vomiting, faintness, vertigo, and convulsive muscular movements. A man took from three to four quarts of a decoction made from a peck of the stalks, and was attacked with pain in the joints, numbness of the limbs, dryness of the mouth, and palsy of the tongue, with consciousness unimpaired, the pulse quiet, but small and rather hard, and the skin cool; followed by recovery. (*Lond. Med. Gaz.*, 1850.) Dulcamara has been recommended in various diseases, but is now chiefly employed in the treatment of cutaneous eruptions, particularly those of a scaly character, as *lepra*, *psoriasis*, and *pityriasis*. In these complaints it is often beneficial, especially in combination with minute doses of the antimonials. It is said to have been beneficially employed in chronic *rheumatism* and chronic *catarrh*. Antaphrodisiac properties have been ascribed to it. The usual form of administration is that of decoction, of which two fluidounces may be taken four times a day, and gradually increased till some slight disorder of the head indicates the activity of the medicine. A fluid extract is official. The dose of the extract is from five to ten grains (0·33–0·65 Gm.), of the fluid extract thirty minims to a fluidrachm (1·9–3·75 C.c.). That of the powder would be from thirty grains to a drachm

de Thérap., July 15, 1887.) The dose of solanine, as given by different writers, varies. Fronmüller has seen as much as 0·5 gramme (7·5 grains) taken without producing anything more serious than marked malaise, general weakness, giddiness, and sleep. Clarus gives the medium dose for adults as 0·01 to 0·06 Gm. ($\frac{1}{6}$ to $\frac{1}{10}$ gr.) of the acetate, and has seen 0·4 Gm. (6 gr.) of the same salt produce general cephalic distress, with occipital pain, dyspnœa, increase of the frequency and loss of the force of the pulse; followed after some hours by sudden vomiting, diarrhœa, great weakness, and marked dyspnœa. Capparoni administered from 0·25 to 0·30 Gm. ($3\frac{3}{4}$ to $4\frac{1}{2}$ gr.) during the twenty-four hours in divided doses. It is probable that much of the solanine that has been used by investigators has been impure; and it would hardly be safe to begin with the pure alkaloid in the dose of more than $\frac{1}{4}$ of a grain, increasing the dose *pro re nata*. Cases of poisoning by potatoes in poor condition have been reported in Germany. (*Arch. f. Exper. Path. u. Pharm.*, xxxvi.) The symptoms have been vomiting and diarrhœa with abdominal pain, headache, giddiness, and pronounced fever (39° C.); it is probable, however, that these manifestations were due to decomposition products rather than to solanine.

* The following reaction is proposed as a test for solanine. Equal measures of concentrated sulphuric acid and alcohol are mixed. A trace of solanine added to the mixture, while warm, produces a rose-red color; larger quantities, a cherry-red color, which disappears after five or six hours, and the intensity of which is not affected by the presence of morphine even in large quantities. (*A. J. P.*, 1873, 484.)

(1·95–3·9 Gm.). In cutaneous affections, a strong decoction is often applied to the skin at the same time that the medicine is taken internally. (See *Extractum Dulcamaræ Fluidum.*)

ELASTICA. U. S. (Br.) India-Rubber. [Caoutchouc.]

(Ē-LĂS'TĮ-CĄ.)

"The prepared milk-juice of various species of Hevea (nat. ord. Euphorbiaceæ), known in commerce as Para Rubber." *U. S.* "The prepared milk-juice of Hevea brasiliensis, Muell. Arg., and probably other species; known in commerce as pure Para rubber." *Br.*

Caoutchouc, *Br.;* Resina elastica, Gummi elasticum; Caoutchouc, *Fr.;* Kautschuk, Federharz, *G.*

India-rubber has been made official in the U. S. P. 1890 because of its use in making mustard paper. Considerable amounts of india-rubber find their way to Europe from the west coast of Africa, especially from the region of the Gambia and from Sierra Leone. Although various plants appear to yield this product, the chief supply is said to come from the *Landolphia florida* and the *Landolphia owariensis.** The great bulk of caoutchouc still enters commerce from South America and India, the finest quality being the Para rubber from Brazil. The chief caoutchouc plant of India is the *Ficus elastica.* This is a very large tree, whose seed usually germinates in the fork of a tree, and gives off as it grows aerial roots, which sink into the ground; by a continuation of this process at last a single tree will be possessed of a great many trunks and cover a large extent of ground. The apocynaceous creeper *Chavannesia esculenta* of India is said to yield caoutchouc, and the milky juice of a Jamaican vine, *Forsteronia floribunda*, is affirmed to yield 22 ounces of excellent caoutchouc for every quart of juice. The most important india-rubber trees of South America belong to the genera Castilloa and Hevea. The first genus belongs to the Artocarpaceæ, and is represented by two or more species (*C. elastica* and *C. markhamiana*), which are scattered over all the equatorial western portions of South America. The genus Hevea occupies the valley of the Amazon, extending up to the Cordilleras. It is composed of large trees with alternate, long-petiolate, digitate, 3-foliolate leaves; the folioles are sessile, or petiolulate penni-nerved, patellar-grandulose at base; the flowers occur in axillary or terminal ramified cymiferous racemes. There are eight species of the genus enumerated by Mr. J. Collins. The commercial caoutchouc is yielded chiefly by *H. guianensis* (= *Siphonia elastica* Pers.) and *H. brasiliensis* (H. B. K.) Müll.-Arg., and comes from Guiana and the Brazilian provinces of Para, Alto Amazonas, Ceará, and Rio Grande. In the southern Brazilian province of Ceará, Mr. Cross, whilst collecting india-rubber plants for the British government, discovered a new tree (*Manihot glaziovii*), resembling in appearance the birch, and yielding to commerce much caoutchouc. Whilst all the other South American rubber plants grow in an excessively moist climate, it flourishes in a dry district. (See Appendix to Markham's *Peruvian Bark*, London, 1880.)

In the Guianas and neighboring countries india-rubber is largely obtained from the *Mimusops balata*, a very large tree, the beauty and permanency of whose wood causes it to be sought after by the cabinet-makers. The cutting down of the tree is said, however, to be in both British and French Guiana forbidden by law. Rubber is now largely produced in Mexico,† being obtained, it is asserted, from eight different species of trees, several of which are largely cultivated.

On being wounded, the various rubber trees emit a milky juice, which concretes on exposure and constitutes the substance in question. In the preparation of the rubber in Mexico, to each barrel of the milk or sap of the tree is added a solution of five ounces of sodium chloride or carbonate in sufficient water to cover the whole mass. After the lapse of from twenty-four to thirty-six hours, with occasional agitation, the water is drawn off from the coagulated rubber, about 44 per cent. of solid material being finally left.

Properties. India-rubber occurs in large flat pieces, or moulded into various shapes. The latter are formed by applying successive layers of the juice upon moulds of clay, which are broken and removed when the coating has attained a sufficient thickness and consistence. In the drying of these layers they are exposed to smoke, which gives to the concrete mass a blackish color. India-rubber is officially described as "in cakes, balls, or hollow, bottle-shaped pieces,

* For a very elaborate monograph upon the genus *Landolphia*, with much discussion of india-rubber Economics, see paper by A. de Wevre. (*Am. Soc. Sci. Bruxelles*, t. xix.)

† The statements of the profits obtained in the cultivation of rubber seem fabulous. In a plantation the preparation and setting out of 100,000 trees is said to cost $25,000, and the first year of harvesting is to be expected to pay this cost and all expenses up to the harvest, and yield a net profit of $95,000; while each of the succeeding harvests for twenty or thirty years will bring a steady income of over $100,000. (*Journal of the Soc. of Arts.*)

externally brown to brownish black, internally brownish or of lighter tint; very elastic; insoluble in water, diluted acids, or diluted solutions of alkalies; soluble in chloroform, carbon disulphide, oil of turpentine, benzin, and benzol. When heated to about 125° C. (257° F.) it melts, remaining soft and adhesive after cooling. Odor faint, peculiar; nearly tasteless. When pure, or nearly pure, india-rubber floats on water." *U. S.* "In elastic masses of varying thickness, brownish black externally and mottled with a pale tint internally; insoluble in *water*, ethylic alcohol, alkaline solutions, or dilute acids, soluble in *chloroform*, *oil of turpentine*, *carbon bisulphide*, *benzol*, and *petroleum spirit*. When heated to about 257° F. (125° C.) it melts, remaining soft and adhesive after cooling. Odor characteristic, somewhat empyreumatic; nearly tasteless." *Br.*

Chemical Constitution. The juice of the india-rubber trees, when it concretes by exposure to the air, assumes on the outer surface a yellowish-brown color, while the mass remains white or yellowish white within. It is said that a little alum facilitates the coagulation, while ammonia retards it; so that a little of the latter may be advantageously added, when it is desired to keep the milky juice in the liquid state. (R. Spruce, *P. J. Tr.*, xv. 118.) The recent juice contains, according to Faraday, 1·9 per cent. of vegetable albumen, traces of wax, 7·13 per cent. of a bitter nitrogenous substance soluble in water and alcohol, 2·9 of a substance soluble in water but insoluble in alcohol, 56·37 of water with a little free acid, and only 31·7 of the pure elastic principle to which chemists have given the name of caoutchouc. Besides these principles, the concrete juice, as it reaches us, generally contains soot, derived from the smoke used in drying it. *Pure caoutchouc*, or india-rubber, is nearly colorless, and in thin layers transparent. It is highly elastic, lighter than water, without taste and smell, fusible at about 120° C. (248° F.), remaining unctuous and adhesive upon cooling, inflammable at a higher temperature, insoluble in water, alcohol, the weak acids, and alkaline solutions, soluble in ether when entirely freed from alcohol, soluble also in chloroform and most of the fixed and volatile oils, though, in the latter, at the expense of its elasticity. It is said, however, that the oils of lavender and sassafras dissolve it without change, and that when precipitated by alcohol from its solution in oil of cajuput it is still elastic. But its best solvents, for practical purposes, are coal-naphta or benzin, the empyreumatic oil obtained by distilling caoutchouc itself, and pure oil of turpentine. According to Dr. Bolley, the best method of effecting its solution, for the preparation of a varnish, is first to digest it, cut in small pieces, in carbon disulphide, which converts it into a jelly, and then to treat this jelly with benzin. A larger proportion is thus taken up than by any other method. (See *A. J. P.*, 1862, p. 414.) India-rubber is not affected by atmospheric air, chlorine, hydrochloric or sulphurous acid gas, or ammonia. Caoutchouc chemically is composed of a mixture of polyterpenes. When destructively distilled, it yields *isoprene*, C_5H_8, and *dipentene*, $C_{10}H_{16}$. When vulcanized, it may contain from 2 to 20 per cent. of sulphur, of which, however, not more than the lower amount is chemically combined, the rest being held mechanically, and capable of removal by treatment with caustic alkalies. Bouchardat succeeded in preparing from isoprene an artificial caoutchouc by acting upon it with saturated hydrochloric acid in sealed tubes.*

Medical Properties and Uses. India-rubber is so insoluble that it cannot be absorbed in any form into the blood. It is used enormously in the arts for an infinite variety of purposes. In chemistry and surgery it has also numerous applications.†

* By the action of sulphur, india-rubber acquires properties which greatly increase its value in the arts. It either becomes pliable, soft, and tough, or, if the amount of sulphur be increased, of a horny consistence, but preserves its elasticity under the influence both of heat and cold, is compressible with great difficulty, and resists the ordinary solvents, such as petroleum and oil of turpentine. In this state it is said to be *vulcanized*. The discovery of the process of *vulcanization* is ascribed to Mr. Charles Goodyear, of New York. (*Chem. Gaz.*, x. 193.) It consists in submitting india-rubber in thin sheets to the action of a mixture composed of 40 parts of carbon disulphide and 1 of sulphur chloride. For fuller details the reader is referred to the *Journ. de Pharm.* (3e sér., xvii. 205.) But the same object may be effected by other methods. When thin layers of india-rubber are immersed for two or three hours in melted sulphur at the heat of 116° C. (240° F.), they are penetrated by the sulphur, but undergo no change of properties. If now heated in an inert medium to a temperature of from 135° C. (275° F.) to 160° C. (320° F.), a chemical reaction takes place, and the vulcanized product is obtained. The same result takes place if the india-rubber be first pounded with from 12 to 20 per cent. of finely-powdered sulphur, and then heated to the temperature requisite for vulcanization. In either case a portion of uncombined sulphur remains mechanically mixed with the vulcanized india-rubber, from which it may be separated by various solvents, such as solutions of caustic soda or potassa, carbon disulphide, oil of turpentine, anhydrous ether, etc. The *desulphurated* product thus obtained, while exempt from the disadvantages arising from the reaction of free sulphur, is more porous than before. (*Ibid.*, xxi. 366.) For details of these two processes,—viz., vulcanization by heat with sulphur or metallic sulphides, and cold vulcanization with solutions of sulphur chloride,—see Sadtler's *Industrial Organic Chemistry*, pp. 99–101.

† An excellent *glue* may be made by dissolving, with the aid of heat and agitation, 3 parts of india-rubber in 30 of naphta, and adding 64 parts of finely-powdered shellac. It may be obtained in sheets by pouring it when hot on plates of metal. (*A. J. P.*, 1867.)

ELATERINUM. U. S., Br. Elaterin.

$C_{20}H_{28}O_5$; 347·20. (ĔL-Ą-TĘ-RI'NŬM.) $C_{20}H_{28}O_5$; 348.

"A neutral principle obtained from Elaterium, a substance deposited by the juice of the fruit of Ecballium Elaterium (Linné), A. Richard (nat. ord. Cucurbitaceæ)." *U. S.* "Elaterin, $C_{20}H_{28}O_5$, is the active principle of Elaterium." *Br.*

This preparation was introduced into the Pharmacopœias on account of the well-known variability in quality of commercial elaterium. (See *Elaterium* and *Trituratio Elaterini.*) Care must be taken to examine the elaterin, which is itself liable to be adulterated. It is in "minute, white, hexagonal scales, or prismatic crystals, without odor, and having a slightly acrid, bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 4250 parts of water, and in 337 parts of alcohol; in 1820 parts of boiling water, and in 34 parts of boiling alcohol; also soluble in 543 parts of ether, or in 2·4 parts of chloroform. At 190° C. (374° F.) the crystals begin to agglutinate, and at about 209° C. (408·2° F.) they melt, forming a yellowish-brown liquid. When ignited, they are consumed without leaving a residue. Elaterin is neutral to litmus paper. Elaterin is dissolved by solutions of the alkalies, and reprecipitated on supersaturating with an acid. When dissolved in cold, concentrated sulphuric acid, it causes the latter to become yellow at first, which color gradually changes to scarlet. An alcoholic solution of Elaterin should not be precipitated by tannic acid test-solution, mercuric chloride test-solution, or platinic chloride test-solution (absence of, and difference from, *alkaloids*)." *U. S.* "With melted phenol it yields a solution which, on the addition of sulphuric acid, acquires a crimson color, rapidly changing to scarlet." *Br.* Ernst Johannson (*Inaug. Diss.*, Dorpat, 1884) gives the following reactions for elaterin besides those mentioned in the Pharmacopœia. In all of them elaterin is held in alcoholic solution. Froehde's reagent gives a green color passing into brown which fades away. Vanadinsulphuric acid with the fortieth of a milligramme produced a splendid blue color passing into a clear green, finally into reddish brown. After mixing with selenic acid and an addition of sulphuric acid, in a few minutes a red-brown color develops, which is not so deep as that which is produced by sulphuric acid. Kohler's reaction is made by dissolving elaterin in a few drops of concentrated hydrochloric acid, evaporating the acid in a water-bath, washing the white, amorphous residue with boiling water, and adding some concentrated sulphuric acid, when an amaranth-red color develops. By means of these reactions Johannson has been able to find elaterin in large quantities in the fæces of animals poisoned by it, but no trace in the blood or urine or any part of the organism. It may be procured by evaporating an alcoholic tincture of elaterium to the consistence of thin oil, and throwing the residue while yet warm into a weak boiling solution of potassa. The potassa holds the green resin in solution, and the elaterin crystallizes as the liquor cools. Mr. Hennell obtained it by treating with ether the alcoholic extract procured by the spontaneous evaporation of the tincture. This consists of elaterin and the green resin, the latter of which, being much more soluble in ether than the former, is completely extracted by this fluid, leaving the elaterin pure. But, as elaterin is also slightly soluble in ether, a portion of this principle is wasted by Mr. Hennell's method. By evaporating the ethereal solution, the green resin is obtained separate. Mr. Hennell says that this was found to possess the purgative property of elaterium, as it acted powerfully in a dose less than one-third of a grain. But the effect was probably owing to the presence of a portion of elaterin which had been dissolved by the ether. Flückiger prefers to exhaust elaterium with chloroform, and add to the percolate ether, which precipitates elaterin. The precipitate may be dissolved in chloroform and recrystallized. This process was adopted by the Br. Pharm. 1885.

Mr. Morries obtained 26 per cent. from the best British elaterium, 15 per cent. from the worst, and only 5 or 6 per cent. from the French; while a portion procured according to the directions of the London College yielded to Mr. Hennell upwards of 40 per cent. The Br. Pharmacopœia directs that the proportion of elaterin should not be less than 20 per cent. Experiments by Mr. John Williams satisfactorily prove that the fruit, exhausted of the free juice from which elaterium is obtained, contains very little if any elaterin, certainly not enough to compensate for the cost of its extraction. (*Chem. News*, 1860, p. 124.)

Medical Properties. Elaterin represents all the activities of elaterium. It would scarcely be safe to begin with more than $\frac{1}{20}$ of a grain (0·003 Gm.); the doses of the Br. Ph. are from $\frac{1}{40}$ to $\frac{1}{10}$ of a grain (0·0016–0·006 Gm.). (See *Trituratio Elaterini.*)

ELATERIUM. Br. Elaterium.

(ĔL-Ą-TĒ′RĮ-ŬM.)

"A sediment from the juice of the fruit of Ecballium Elaterium." *Br.*

Extractum Elaterii; Elaterium, Elaterion, *Fr.;* Elaterium, *G.;* Elaterio, *It., Sp.*

Momordica elaterium. Willd. *Sp. Plant.* iv. 605; Woodv. *Med. Bot.* 192, t. 72.—*Ecbalium agreste.* Richard; Lindley, *Med. and Œcon. Bot.* 95.—*Ecbalium officinarum.* Br.—*Ecbalium elaterium.* French Codex, 1837. The *wild* or *squirting cucumber* is a perennial plant, with a large fleshy root, from which rise several round, thick, rough stems, branching and trailing like the common cucumber, but without tendrils. The leaves are petiolate, large, rough, irregularly cordate, and of a grayish-green color. The flowers are yellow, and proceed from the axils of the leaves. The fruit has the shape of a small oval cucumber, about an inch and a half long, an inch thick, of a greenish or grayish color, and covered with stiff hairs or prickles. When fully ripe, it separates from the peduncle, and throws out its juice and seeds with considerable force through an opening at the base, where it was attached to the footstalk. The name of squirting cucumber was derived from this circumstance, and the scientific and official title is supposed to have had a similar origin; though some authors maintain that the term *elaterium* was applied to the medicine rather from the mode of its operation upon the bowels than from the projectile property of the fruit.*

This species of Momordica is a native of the south of Europe, and is cultivated in Great Britain, where, however, it perishes in the winter. Elaterium is the substance spontaneously deposited by the juice of the fruit, when separated and allowed to stand. From the experiments of Dr. Clutterbuck, it has been supposed that only the free juice about the seeds, which is obtained without expression, affords the product. The substance of the fruit itself, the seeds, as well as other parts of the plant, have been thought to be nearly or quite inert. From the statements made by Mr. Bell (see note below), these opinions must probably be somewhat modified; but there is no doubt that strong expression injures the product. When the fruit is sliced and placed upon a sieve, a perfectly limpid and colorless juice flows out, which soon becomes turbid, and in the course of a few hours begins to deposit a sediment. This, when collected and carefully dried, is very light and pulverulent, of a yellowish-white color, slightly tinged with green. It is the genuine elaterium, and was found by Clutterbuck to purge violently in the dose of one-eighth of a grain. But the quantity contained in the fruit is very small. Clutterbuck obtained only six grains from forty cucumbers. Commercial elaterium is often a weaker medicine, owing in part, perhaps, to adulteration, but much more to the mode in which it is prepared. In order to increase the product, the juice of the fruit is often expressed with great force; and there is reason to believe that it is sometimes evaporated so as to form an extract, instead of being allowed to deposit the active matter. The French elaterium is prepared by expressing the juice, clarifying it by rest and filtration, and then evaporating to a suitable consistence. As the liquid remaining after the deposition of the sediment is comparatively inert, it will be perceived that the preparation of the French Codex must be relatively feeble. The following are the directions of the British Pharm. (1885): "Cut the fruit lengthwise, and lightly press out the juice. Strain it through a hair sieve, and set aside to deposit. Carefully pour off the supernatant liquor; pour the sediment on a linen filter, and dry it on porous tiles, in a warm place. The decanted fluid may deposit a second portion of sediment, which can be dried in the same way." The latter portion deposited is of a lighter color. (*Pereira.*) The slight pressure directed is necessary for the separation of the juice from the somewhat immature fruit employed. The perfectly ripe fruit is not used, as, in consequence of its disposition to part with its contents, it cannot be carried to market. In the British Pharmacopœia, the former name of Extractum Elaterii of the London College has been very properly abandoned, as the preparation is in no correct sense of the word an extract. Elaterium is brought chiefly from England; but it is probable that a portion of the elaterium of which Dr. Pereira speaks as coming from Malta reaches our market also.†

* From the Greek ἐλαύνω, *I drive,* or ἐλατήρ, *driver.* The word *elaterium* was used by Hippocrates to signify any active purge. Dioscorides applied it to the medicine of which we are treating.

† The following notice of the cultivation of the elaterium plant and the preparation of the drug at Mitcham, in Surrey, England, condensed from a paper by Mr. Jacob Bell in the *P. J. Tr.* for October, 1850, may have some interest for the American reader. The seeds are sown in March, and the seedlings planted in June. In luxuriant plants the stem sometimes acquires an extraordinary breadth. In one instance, though not thicker than the forefinger where it issued from the earth, it was in its broadest part four inches wide and half an inch thick. A wet season interferes with the productiveness of the plant. At the spontaneous separation of the fruit, it throws out its juice sometimes to the distance of twenty yards; and hazard of injury to the eyes is incurred by walking among the plants at their period of maturity. A bushel of the fruit weighs 40 pounds, and the price varies from 7 to 10 shillings sterling.

Properties. The *best elaterium* is in thin flat or slightly curled cakes or fragments, often bearing the impression of the muslin upon which it was dried, of a greenish-gray color becoming yellowish by exposure, of a feeble odor, and a bitter somewhat acrid taste. It is pulverulent and inflammable, and so light that it swims when thrown upon water. When of *inferior quality*, it is sometimes dark-colored, much curled, and rather hard, breaking with difficulty, or presenting a resinous fracture. "In light, friable, flat or slightly curved, opaque cakes, about one-tenth of an inch (two and a half millimetres) thick; pale green, grayish green, or yellowish gray in color; fracture finely granular; odor faint, tea-like; taste bitter and acrid. It should not give the characteristic reactions with the tests for carbonates or for starch, and should yield half its weight to boiling *alcohol* (90 per cent.). When exhausted with *chloroform*, the solution evaporated, the residue washed with *ether*, and the process of solution, evaporation, and washing repeated, Elaterium should yield 25 per cent., or not less than 20 per cent., of Elaterin." *Br.* The *Maltese elaterium* is in larger pieces, of a pale color, sometimes without the least tinge of green, destitute of odor, soft, and friable, and not infrequently gives evidence of having been mixed with chalk or starch. It sinks in water, and usually contains so little elaterin that it should be employed only as a source of that principle.*

Dr. Clutterbuck first observed that the activity of elaterium resided in the portion of it soluble in alcohol and not in water. This fact was afterwards confirmed by Dr. Paris, who found that the alcoholic extract, treated with boiling distilled water, and afterwards dried, had the property of purging in minute doses, while the remaining portion of the elaterium was inactive. The subsequent experiments of Mr. Hennell, of London, and Mr. Morries, of Edinburgh, which were nearly simultaneous, demonstrated the existence of a crystallizable matter in elaterium which is the active principle, and has been named *elaterin*.† (See *Elaterinum*.) According to Mr. Hennell, 100 parts of elaterium contain 44 of elaterin, 17 of a green resin (*chlorophyll*), 6 of starch, 27 of lignin, and 6 of saline matters. The alcoholic extract which Dr. Paris called *elatin* is probably a mixture of elaterin and the green resin or chlorophyll.‡

In the manufacture of elaterium, which begins early in September, the fruit, having been washed, if necessary, to cleanse it from earthy matters, is sliced longitudinally into halves, and then submitted to expression, wrapped in a hempen cloth, in a common screw-press. Considerable force is used in the expression. The juice is then strained through hair, cypress, or wire sieves, and set aside for deposition. The deposit usually takes place in three or four hours. When this part of the process is completed, the supernatant liquor is carefully poured off, the deposit is placed on calico cloths resting on hair sieves, and allowed to drain for about twelve hours, after which it is removed by a knife, spread over small cloths, and dried on canvas frames in the drying-stove. About half an ounce of fine elaterium is obtained from a bushel of fruit. Some obtain more; but the product is inferior, in consequence of the use of too much force in the expression. Good elaterium has a pale pea-green tint; that of inferior quality is of a duller hue. The juice expelled in bursting is said to undergo very little change in the air, while that expressed from the ripe fruit immediately afterwards becomes milky, and deposits elaterium. The recently burst fruit, therefore, is nearly if not quite as good for the preparation of the drug as that collected before perfect maturity. For a paper on the cultivation of the elaterium plant at Hitchin, Herts, England, see *A. J. P.*, 1860, p. 163; at Market Deeping, *P. J. Tr.*, Sept. 1881, p. 239.

* In the analyses of T. A. Elwood, the average yield of English elaterium was 21·5 per cent., of Maltese elaterium 15·3 per cent. (*P. J. Tr.*, Nov. 1891.)

† H. W. Jones and F. Ransom detail an improved method of assaying elaterium in the *Year-Book of Pharmacy*, 1886, p. 442: it is as follows: "Macerate 1 gramme of finely powdered elaterium with chloroform in a covered dish for a few hours, then transfer to a miniature glass percolator (*e.g.*, the barrel of a small glass syringe) plugged with cotton, and wash with chloroform, allowing about 10 C.c. to pass through the marc after the menstruum has begun to pass in a colorless condition. Place the percolate in a small dish, and evaporate off the chloroform at a gentle heat. Treat the residue with a small quantity of pure, absolute ether, and transfer to a small percolator or funnel, plugged with cotton. Wash with pure ether until at least 10 C.c. have passed through colorless, and reserve the ethereal washings. Redissolve the elaterin, so obtained, by passing chloroform through it whilst still in the funnel or percolator, and evaporate the chloroformic solution once more to dryness in a small dish. Treat the residue so obtained with ether, exactly as before. Allow the united ethereal washings to evaporate spontaneously until the bulk is reduced to about 3 C.c. Transfer this liquid to a small cylinder (*e.g.*, a 10 C.c. measure), and allow the separated elaterin to deposit. Carefully decant the colored supernatant liquid, add 4 C.c. of pure ether to the residue, and again decant after deposition has taken place. Finally dissolve the elaterin in the cylinder with the aid of chloroform, and wash out the larger amount previously collected in the funnel with the same solvent. Unite the chloroformic solutions, evaporate in a tared dish, dry on a water-bath, and weigh."

‡ *Chlorophyll.* The substance to which Pelletier gave this name, under the impression that it was a peculiar proximate principle, was subsequently supposed by that chemist to be a mixture of wax and a green fixed oil. (*Journ. de Pharm.*, xix. 109.) Afterwards, M. Frémy succeeded, by the joint action of a menstruum composed of two parts of ether and one of hydrochloric acid diluted with a little water, in separating chlorophyll into two coloring principles, one yellow and the other blue; the former being dissolved by the ether, and the latter by the hydrochloric acid. The yellow, M. Frémy proposed to name *phylloxanthin*, the blue *phyllocyanin*. (*Ibid.*, Avril, 1860.)

Phylloxanthin is neutral, insoluble in water, soluble in alcohol and ether, and crystallizable, sometimes in yellow plates, sometimes in reddish prisms, resembling potassium bichromate, and possessing dyeing powers analogous to those of chromic acid.

Phyllocyanic acid is soluble in water, alcohol, and ether, giving to these an olive-like color, with bronze-red or violet reflections. All its salts are brown or green; but only the alkaline are soluble in water. This acid dissolves in sulphuric and hydrochloric acids, giving rise to solutions which, according to their strength, are green, reddish, violet, or

Walz (1859) found in the juice of the fruits and herb of *Ecballium*, as well as in that of *Cucumis prophetarum*, L., a second crystallizable bitter principle, *prophetin*, and the amorphous substances *ecballin* or *elateric acid*, *hydro-elaterin*, and *elateride*, all of which require further examination.

Choice of Elaterium. The inequality of elaterium depends probably more on diversities in the mode of preparation than on adulteration. Sometimes, however, it is greatly sophisticated; and large quantities are said to have been imported into this country consisting mainly of chalk colored green artificially. (B. Canavan, *N. Y. Journ. of Pharm.*, iii.) It should possess the sensible properties above indicated as characterizing good elaterium, should not effervesce with acids, and should yield from one-sixth to one-fourth of elaterin. (See *Elaterinum*.)

Medical Properties and Uses. Elaterium is a powerful hydragogue cathartic, and in a large dose generally excites nausea and vomiting. If too freely administered, it operates with great violence upon both the stomach and bowels, producing inflammation of these organs, which has in some instances eventuated fatally. It also increases the flow of urine. The fruit was employed by the ancients, and is recommended in the writings of Dioscorides as a remedy in mania and melancholy. Sydenham and his contemporaries considered elaterium highly useful in dropsy; but, in consequence of some fatal results from its incautious employment, it fell into disrepute, and was generally neglected till again brought into notice by Dr. Ferriar. It is now considered one of the most efficient hydragogue cathartics in the treatment of *dropsy*. The full dose of commercial elaterium as formerly found in commerce was often from one to two grains (0·065–0·13 Gm.); but, as the quality has greatly improved, this dose might now be much too large, and the best plan is to give it in the dose of a sixth to a quarter of a grain (0·01 to 0·016 Gm.), repeated every hour till it operates, and increased if necessary. It should be observed that these doses are inapplicable to the very old and feeble and those prostrated by disease. Two-fifths of a grain proved fatal by purging in an ill and feeble lady of 70 years. (*A. J. P.*, 1868, p. 373.) The dose of Clutterbuck's elaterium is the eighth of a grain (·008 Gm.), that of elaterin is from the twentieth to the sixteenth of a grain (0·003 to 0·004 Gm.). One grain may be dissolved in a fluidounce of alcohol with four drops of nitric acid, and from 25 to 30 minims may be given diluted with water, but the granule affords a preferable method.

ELIXIRIA. Elixirs.

(ĔL-ĮX-ĬR'Ĭ-Ą.)

Elixirs as they are known in modern American pharmacy are aromatic, sweetened, spirituous preparations, containing small quantities of active medicinal substances. They differ greatly from the liquids formerly termed elixirs, from the fact that the first object sought for in the modern elixir is an agreeable taste, and usually this is attained only by such sacrifices as to render the effect of the medicine almost *nil*, whilst the principal activity is due to the alcohol, which has proved in many cases very injurious. These considerations have heretofore prevented an official recognition of elixirs, and the U. S. Pharm. 1890 recognizes but two, one of which, the Aromatic Elixir, has been introduced merely as a vehicle. Owing to their extensive use by practitioners all over our country, it became necessary to notice some of the most important in this commentary, and in the 15th edition of the Dispensatory a number of formulas for elixirs were inserted in PART I.; but, as an extensive list is now to be found in the National Formulary, and as these have a semi-official standing, it has been deemed best to group all the elixirs together under their proper titles in PART II., *q. v.* Elixir of Orange, official in the U. S. Pharm. 1880, may be made by the formula in the foot-note.*

beautifully blue. This M. Frémy considers the important fact of the investigation, as it explains the various tints which chlorophyll offers in vegetation.

Several quite thorough studies of chlorophyll color have been made since, notably that of Tschirch. (*P. J. Tr.* [2], 21, pp. 370–376.) The crude extract of chlorophyll always contains, associated with the two coloring matters *phyllocyanin* and *phylloxanthin*, *chlorophyllan*, an oxidation product of the crude chlorophyll. The purest chlorophyll is prepared by heating an alcoholic solution of the chlorophyllan with zinc dust. Thus obtained, it yields an emerald-green solution with alcohol, which fluoresces red quite strongly and shows the same absorption spectrum as the living plant.

The treatment of chlorophyllan with alcoholic potash changes it into *chlorophyllanic acid*; heating with strong hydrochloric acid, on the other hand, changes either chlorophyll or chlorophyllan into *phyllocyanic acid* and phylloxanthin.

* *Elixir Aurantii. U. S. Elixir of Orange. Simple Elixir.* "Oil of Orange Peel, *one part* [or two and a half fluidrachms]; Cotton, *two parts* [or half an ounce av.]; Sugar, in coarse powder, *one hundred parts* [or twenty-five ounces av.]; Alcohol, Water, each, *a sufficient quantity*, To make *three hundred parts* [about four pints]. Mix Alcohol and Water in the proportion of *one part* [or one pint] of Alcohol to *three parts* [or two and a half pints] of Water. Add the Oil of Orange to the Cotton, in small portions at a time, distributing it thoroughly by picking the

ELIXIR AROMATICUM. U. S. Aromatic Elixir.

(Ę-LĬX'ĮR ĂR-Ọ-MĂT'Į-CŬM.)

"Compound Spirit of Orange, *twelve cubic centimeters* [or 195 minims]; Syrup, *three hundred and seventy-five cubic centimeters* [or 12 fluidounces, 326 minims]; Precipitated Calcium Phosphate, *fifteen grammes* [or 231 grains]; Deodorized Alcohol, Distilled Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. To the Compound Spirit of Orange add enough Deodorized Alcohol to make *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims]. To this solution add the Syrup in several portions, agitating after each addition, and afterwards add, in the same manner, *three hundred and seventy-five cubic centimeters* [or 12 fluidounces, 326 minims] of Distilled Water. Mix the Precipitated Calcium Phosphate intimately with the liquid, and then filter through a wetted filter, returning the first portions of the filtrate until a transparent liquid is obtained. Lastly, wash the filter with a mixture of *one volume* of Deodorized Alcohol and *three volumes* of Distilled Water, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official preparation. It takes the place of the former elixir of orange, and by many is regarded as more agreeable. Its introduction grew out of the necessity for some official action which would enable pharmacists readily to furnish elixirs when called for by an extemporaneous or speedy process. The aromatic elixir is, of course, merely a base or vehicle, and in many cases the medicinal substance may be simply dissolved in the elixir. It may be necessary to add some insoluble, inert powder, like precipitated chalk, magnesium carbonate, etc., to the liquid before filtering, in order to obtain a perfectly transparent elixir, and it is customary in many parts of the country to color the preparation with cochineal or caramel. (See PART II. for formulas for various elixirs.)

ELIXIR PHOSPHORI. U. S. Elixir of Phosphorus.

(Ę-LĬX'ĮR PHŎS'PHỌ-RĪ.)

"Spirit of Phosphorus, *two hundred and ten cubic centimeters* [or 7 fluidounces, 48 minims]; Oil of Anise, *two cubic centimeters* [or 32 minims]; Glycerin, *five hundred and fifty cubic centimeters* [or 18 fluidounces, 287 minims]; Aromatic Elixir, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. To the Spirit of Phosphorus, contained in a graduated bottle, add the Oil of Anise and Glycerin, and mix them by repeatedly inverting the bottle, until they form a clear liquid. Then add Aromatic Elixir, in several portions, gently agitating after each addition, until a transparent liquid is obtained, and the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Keep the product in dark amber-colored, well-stoppered bottles, in a cool and dark place." *U. S.*

Each cubic centimeter of this new official preparation represents about *one-fourth milligramme* (0·00025 Gm., or $\frac{1}{260}$ grain) of phosphorus. A teaspoonful of the recently-made elixir contains about $\frac{1}{65}$ grain (0·001 Gm.) of phosphorus. Dose, from twenty to forty minims.

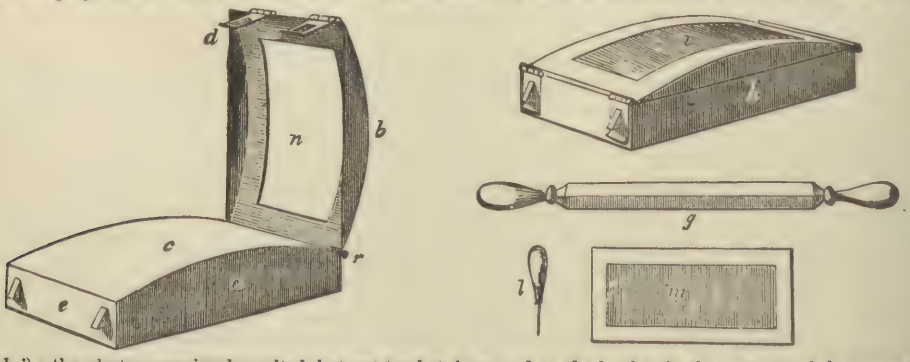
EMPLASTRA. Plasters.

(Ę̆M-PLĂS'TRĄ.)

Emplâtres, *Fr.*; Pflaster, *G.*

Plasters are solid compounds intended for external application, adhesive at the temperature of the human body, and of such a consistence as to render the aid of heat necessary in spreading them. Spread plasters having rubber in their composition are most largely used; they are usually perforated. Some plasters have as their basis a compound of olive oil and litharge, constituting the Emplastrum Plumbi of the Pharmacopœias. Others owe their consistence and adhesiveness to resinous substances, or to a mixture of these with wax and fats.

In the preparation of the plasters, care is requisite that the heat employed be not sufficiently elevated to produce decomposition, nor so long continued as to drive off any volatile ingredient upon which the virtues of the preparation may in any degree depend. After having been prepared, they are usually shaped into cylindrical rolls, and wrapped in paper to exclude the air. Plasters should be firm at ordinary temperatures, should spread easily when heated, and, after being spread, should remain soft, pliable, and adhesive, without melting, at the heat of the human body. When long kept, they are apt to change color and to become hard and brittle;



Cotton apart after each addition; then pack tightly in a conical percolator, and gradually pour on the mixture of Alcohol and Water, until *two hundred parts* [or three and a quarter pints] of filtered liquid are obtained. In this liquid dissolve the Sugar by agitation, without heat, and strain." *U. S.*

and, as this alteration is most observable upon their surface, it must depend chiefly upon the action of the air, which should therefore be as much as possible excluded. The defect may usually be remedied by melting the plaster with a moderate heat and adding a sufficient quantity of oil to give it the due consistence.

Plasters are prepared for use by spreading them upon leather, linen, or muslin, according to the particular purposes they are intended to answer. Leather is most convenient when the application is made to the sound skin, linen or muslin when the plaster is used as a dressing to ulcerated or abraded surfaces, or with the view of bringing and retaining together the sides of wounds. The leather usually preferred is white sheepskin, or the kind known commercially as "hemlock splits." A margin about a quarter or half an inch broad should usually be left uncovered, in order to facilitate the removal of the plaster, and to prevent the clothing in contact with its edges from being soiled. An accurate outline may be obtained by pasting upon the leather a piece of paper so cut as to leave in the centre a vacant space of the required dimensions, and removing the paper when no longer needed. The same object may often be accomplished by employing two narrow rulers of sheet tin graduated in inches, and so shaped that each of them may form two sides of a rectangle. These may be applied in such a manner as to enclose within them any given rectangular space, and may be fixed by weights upon the leather, or preferably adjusted by set-screws, while the plaster is spread. For any other shape, as in the instance of plasters for the breast, pieces of tin may be employed having a vacuity within, corresponding to the required outline. The spreading of the plaster is most conveniently accomplished by the use of a spatula or plaster-iron. This may be heated by means of a spirit-lamp. Care must be taken that the instrument be not so hot as to discolor or decompose the plaster; and special care is requisite in the case of those plasters which contain a volatile ingredient. A sufficient portion of the plaster should first be melted by the heated instrument, and, having been received on a piece of coarse stiff paper, or in a shallow tin tray open on one side, should, when nearly cool, be transferred to the leather, and applied quickly and evenly over its surface. By this plan the melted plaster is prevented from penetrating the leather, as it is apt to do when applied too hot. Before removing the paper from the edge of the plaster, if this has become so hard as to crack, the iron should be drawn over the line of junction. When linen or muslin is used, and the dimensions of the portion to be spread are large, as is often the case with adhesive plaster, the best plan is to pass the cloth "on which the plaster has been laid through a machine formed of a spatula fixed by screws at a proper distance from a plate of polished steel." A machine for spreading plasters is described by M. Hérent in the *Journ. de Pharm.* (3e sér., ii. 403).* (See also *N. R.*, 1879, p. 337.)

The spreading of plasters has become to a great extent a lost art to the pharmacist of this country, owing to the introduction of machine-spread plasters, which contain india-rubber

* It has been customary with apothecaries to employ an apparatus, such as that shown in the illustration, for spreading quantities of plasters. An oblong rectangular block of hard wood (*a e*) has its upper surface (*c*) slightly convex. To this is attached by a movable joint (at *r*) a sheet-iron frame (*b*), with an opening (*n*) of the dimensions of the plaster to be spread, and clasps (*d*) at the other end, by which this may be fixed to the block. Another portion of the apparatus is a sheet-iron or tin frame (*m*), by which the leather is cut out, and the margin marked. The leather thus prepared is laid on the convex surface of the block (*c*); the sheet-iron frame is brought down on it evenly

(as at *h i*); the plaster, previously melted, but not too hot, is poured on the leather in the centre, and, by means of an iron instrument (*g*) previously heated by a spirit-lamp, is spread uniformly over the surface, the thickness being regulated by the frame against which the iron is pressed. Any excess of plaster is thus pressed over upon the frame. The point of a sharp instrument (*l*) is then drawn along the interior edge of the frame so as to separate the plaster from it, after which the clasps are unfastened and the plaster removed.

in the adhesive composition. These are reasonably permanent, and do not require the application of heat. When made by reliable manufacturers they are in many cases to be preferred; but the introduction of immense quantities of worthless ones by unscrupulous makers has caused many practitioners to direct plasters to be spread by the pharmacist from official plaster. The perforation or "porousing" of plasters is usually accomplished on a large scale by expensive apparatus. Prof. J. P. Remington has devised an inexpensive apparatus whereby the apothecary can perforate those spread by himself. (*A. J. P.*, 1878, p. 171.)* Dr. J. J. Edmondson read a paper before the Pennsylvania Pharmaceutical Association in 1887 giving the process for manufacturing rubber-mass plasters as carried on by Johnson & Johnson, of New York. It is as follows. The ingredients employed are—rubber, two parts; Burgundy pitch, one part; gum olibanum, one part. This may vary with some special plasters, but they constitute the component parts of the mass used for the majority.

The crude rubber is at first steeped in hot water, to cleanse and soften it, then the rubber is passed through the washer and crusher, where it is subjected to severe pressure between two corrugated rolls, eight inches in diameter and one foot wide, while a stream of water falling continually washes it thoroughly, and it comes out in sheets somewhat softened. After these sheets are dried, which requires a number of days, they are passed through the grinder, where they are crushed between two smooth rollers, fourteen inches in diameter and thirty-six inches across. This thoroughly softens the rubber and makes it plastic, so that it can be readily worked up with the other ingredients. The principal operation, the mixing, then takes place. The medication must be carefully combined, and the whole manipulation so managed that the plaster will be uniform, so that age or varying temperature shall not affect it. This operation is performed by means of rollers, sixteen inches in diameter, arranged so that one revolves at twice the speed of the other. Between these large rollers the mass is passed with whatever medication is required: *e.g.*, when a belladonna mass is to be made, a certain amount of the stock mass is taken and of extract of belladonna in proportions corresponding to the formula in the Pharmacopœia. These are repeatedly passed through the rollers until the extract of belladonna is thoroughly mixed with the mass, care being taken to keep the temperature from rising high enough to decompose or affect the alkaloids. The spreading is also done by rollers, into which the thoroughly-mixed mass is fed at the same time that the cloth is fed, the thickness of the plasters being governed by adjusting-screws on the side of the machine. The rubber base is pliable, adhesive, will not become too hard or too soft, will yield up the medication to the absorbents of the skin, and will retain its properties indefinitely.†

EMPLASTRUM AMMONIACI CUM HYDRARGYRO. U. S., Br. Ammoniac Plaster with Mercury.

(ĘM-PLĂS'TRŲM ĂM-MŌ-NĪ'Ą-CĪ CŬM HŸ-DRĂR'ĢŲ-RŌ.)

Ammoniacum and Mercury Plaster; Emplâtre de Gomme Ammoniaque mercuriel, *Fr.;* Quecksilber- und Ammoniak-Pflaster, *G.*

"Ammoniac, *seven hundred and twenty grammes* [or 25 ounces av., 173 grains]; Mercury, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Oleate of Mercury, *eight grammes* [or 123 grains]; Diluted Acetic Acid, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]; Lead Plaster, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Digest the Ammoniac with the diluted Acetic Acid, in a suitable

* *Emplastrum Aconiti. Aconite Plaster.* (Emplâtre d'Aconit, *Fr.;* Aconit-Pflaster, *G.*) "Take of Aconite Root, in fine powder, *sixteen troyounces;* Alcohol, Resin Plaster, each, *a sufficient quantity.* Moisten the Aconite Root with six fluidounces of Alcohol, and pack it in a conical percolator. Cover the surface with a disk of paper, and pour upon it ten fluidounces of Alcohol. When the liquid begins to drop, cork the percolator, and, having closely covered it to prevent evaporation, set it aside in a moderately warm place for four days. Then remove the cork, and gradually pour on Alcohol until two pints of tincture have been obtained or the Aconite Root is exhausted. Distil off a pint and a half of alcohol, and evaporate the residue to a soft uniform extract by means of a water-bath. Add to this sufficient Resin Plaster, previously melted, to make the mixture weigh sixteen troyounces, and then mix them thoroughly." *U. S.* 1870.

This plaster was introduced into the Pharmacopœia of 1870. The formula is a modification of that proposed by Prof. Procter. (*A. J. P.*, xxv. 202.) Aconite Plaster may be used whenever it is desired to produce a very powerful local anodyne effect.

† *Unna's Plaster Mulls. Plaster mulls* have been introduced as superior to spread plasters; fine gauze is covered with the thinnest possible layer of gutta-percha or rubber, on which the medicament is evenly spread, properly dissolved in or mixed with a small quantity of vehicle or base. Their pliability, thinness, adhesiveness, porosity, and rapidity of action are the chief advantages. Dr. Unna, under the name of *paraplast* (1898), proposes to use a fine, thick cotton web, spread with a mixture of the medicating agent and rubber, lanolin, resin, and dammar, in proper proportions.

vessel, avoiding contact with metals, until it is entirely emulsified; then strain, and evaporate the strained liquid by means of a water-bath, stirring constantly, until a small portion, taken from the vessel, hardens on cooling. Triturate the Oleate of Mercury with the Mercury gradually added, until globules of the metal cease to be visible. Next add, gradually, the Ammoniac, while yet hot; and finally, having added enough Lead Plaster, previously melted by means of a water-bath, to make the mixture weigh *one thousand grammes* [or 35 ounces av., 120 grains], mix the whole thoroughly." *U. S.*

"Ammoniacum, 12 *ounces* (Imperial) or 328 grammes; Mercury, 3 *ounces* (Imp.) or 82 grammes; Olive Oil, 56 *grains* (Imp.) or 3·5 grammes; Sublimed Sulphur, 8 *grains* (Imp.) or 0·5 gramme. Heat the Olive Oil; add the Sulphur to it gradually, stirring until they are uniformly blended; with this mixture triturate the Mercury until metallic globules are no longer visible; add the Ammoniacum, previously purified by boiling with successive portions of water, passing the resulting emulsions through, while rubbing the residues on, a hair sieve, and, after mixing, evaporating the emulsions to a suitable consistence." *Br.*

Ammoniac plaster (*Emplastrum Ammoniaci*, U. S. P., 1880) is not recognized in the last U. S. and Br. Pharmacopœias. (See *U. S. D.*, 17th ed., 492.) Ammoniac plaster with mercury does not differ materially from that produced by the formula of the last Pharmacopœia. The use of diluted acetic acid to facilitate the straining of the ammoniac is an improvement over the water formerly used. The use of lead plaster to bring up the weight is needless, in our opinion. The only use of the oleate of mercury is to aid in the extinguishment of the mercury; the compound formed by it probably adds to the efficiency. When ammoniac not previously prepared is used, as it is not fusible by heat, it must be brought to the proper consistence by softening it in a small quantity of hot water, straining, and evaporating. This plaster unites with the stimulant power of the ammoniac the specific properties of the mercury, which is sometimes absorbed in sufficient quantity to affect the gums. It is used as a discutient in enlargement of the glands, tumefaction of the joints, nodes, and other indolent swellings, especially when dependent on a venereal taint. It is also sometimes applied over the liver in *chronic hepatitis*.*

EMPLASTRUM ARNICÆ. U. S. Arnica Plaster.

(ĘM-PLĂS'TRUM ĂR'NĮ-ÇÆ—ăr'nį-sē.)

Emplâtre d'Arnique, *Fr.;* Arnicapflaster, *G.*

"Extract of Arnica Root, *three hundred and thirty grammes* [or 11 ounces av., 280 grains]; Resin Plaster, *six hundred and seventy grammes* [or 23 ounces av., 277 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Add the Extract to the Resin Plaster, previously melted by means of a water-bath, and mix them thoroughly." *U. S.*

These ingredients incorporate readily, and form a good plaster. The preparation was introduced into the Pharmacopœia to enable the apothecary to meet the demand for a convenient preparation of arnica for external use. It is supposed to be useful in *sprains* and *bruises*, and sometimes probably acts beneficially by its stimulant properties in *chronic rheumatism* and other chronic external inflammations.

EMPLASTRUM BELLADONNÆ. U. S., Br. Belladonna Plaster.

(ĘM-PLĂS'TRUM BĔL-LĄ-DŎN'NÆ.)

Emplâtre de Belladone, *Fr.;* Belladonna-Pflaster, *G.*

"Alcoholic Extract of Belladonna Leaves, *two hundred grammes* [or 7 ounces av., 24 grains]; Resin Plaster, *four hundred grammes* [or 14 ounces av., 48 grains]; Soap Plaster, *four hundred grammes* [or 14 ounces av., 48 grains]. To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the plasters on a water-bath; then add the Extract of Belladonna Leaves, and continue the heat, stirring constantly, until a homogeneous mass results." *U. S.*

"Liquid Extract of Belladonna, 4 *fl. ounces* (Imperial measure) or 100 cubic centimetres; Resin Plaster, 5 *ounces* (Imp.) or 125 grammes. Evaporate the Liquid Extract of Belladonna on a water-bath until it is reduced in weight to *one ounce* (Imp.) or twenty-five grammes);

* *Emplastrum Antimonii. Antimonial Plaster.* (Emplastrum Stibiatum, s. Antimoniale; Emplâtre (Poix) émétisée, Emplâtre antimonial, *Fr.;* Brechweinstein-Pflaster, *G.*) "Take of Tartrate of Antimony and Potassium, in fine powder, *a troyounce;* Burgundy Pitch *four troyounces.* Melt the Pitch by means of a water-bath, and strain; then add the powder, and stir them well together until the mixture thickens on cooling." *U. S.* 1870.

This is a useful formula, although no longer official. It affords one of the most convenient methods of obtaining the local pustulating effects of tartar emetic. For its effects and uses, see *Antimonii et Potassii Tartras.*

add the Resin Plaster previously melted; mix. This Plaster contains 0·5 per cent. of the alkaloids of Belladonna Root." *Br.*

This plaster was formerly prepared, in both Pharmacopœias, with the extract made from the inspissated juice of the leaves; but in the U. S. P. 1880 an alcoholic extract of the root was substituted, with the effect of rendering the plaster easier to be spread and more adhesive, and giving it a light yellowish-brown color, without a shade of green. The official preparation is now of a brownish-green color, due to the extract of belladonna leaves. It is a useful anodyne application in *neuralgic* and *rheumatic pains*, and in *dysmenorrhœa*. We have seen the constitutional effects of belladonna result from its external use. Mr. T. W. Worthington proposes a formula for making belladonna plaster with caoutchouc in the *A. J. P.*, xliii. 153. (See page 499.) Machine-spread belladonna plaster can be found in the market which was admitted by a representative of the manufacturer to contain no extract of belladonna whatever. For methods of assaying belladonna plasters, see *A. J. P.*, 1898, 182, 293.

EMPLASTRUM CANTHARIDIS. Br. Cantharides Plaster.

(ĘM-PLĂS'TRŲM CĄN-THĂR'Į-DĪS.)

See *Ceratum Cantharidis*. U. S.

EMPLASTRUM CAPSICI. U. S. Capsicum Plaster.

(ĘM-PLĂS'TRŲM CĂP'SĮ-CĪ.)

"Oleoresin of Capsicum, Resin Plaster, each, *a sufficient quantity*. Melt the Resin Plaster at a gentle heat, spread a thin and even layer of it upon muslin, and allow it to cool. Then, having cut off a piece of the required size, apply a thin coating of Oleoresin of Capsicum, by means of a brush, leaving a narrow, blank margin along the edges. A space of *ten centimeters* [$3\frac{15}{16}$ inches] square should contain about *twenty-five centigrammes* [or 4 grains] of Oleoresin of Capsicum." *U. S.*

This affords a convenient way of obtaining the rubefacient effects of capsicum; of course the practice will be for the pharmacist to employ machine-spread adhesive plaster as the base; although, with a little experience, very good work can be done by hand.

EMPLASTRUM FERRI. U. S. Iron Plaster. [Strengthening Plaster.]

(ĘM-PLĂS'TRŲM FĔR'RĪ.)

Emplastrum Roborans, *Br.* 1867; Chalybeate Plaster; Emplastrum Ferratum, s. Martiale; Emplâtre d'Oxyde rouge de Fer, Emplâtre de Canet, *Fr.*; Eisenpflaster, Stärkendes Pflaster, *G.*

"Ferric Hydrate, dried at a temperature not exceeding 80° C. (176° F.), *ninety grammes* [or 3 ounces av., 76 grains]; Olive Oil, *fifty grammes* [or 1 ounce av., 334 grains]; Burgundy Pitch, *one hundred and forty grammes* [or 4 ounces av., 410 grains]; Lead Plaster, *seven hundred and twenty grammes* [or 25 ounces av., 173 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Lead Plaster and Burgundy Pitch by means of a water-bath, and add the Olive Oil; then add the Ferric Hydrate, and stir constantly until the mixture thickens on cooling." *U. S.*

The U. S. P. 1880 preparation differed from that official in 1870 in the substitution of ferric hydrate for ferrous subcarbonate, and of Canada turpentine for a portion of the Burgundy pitch. This latter change proved of questionable utility, the object having been to render the plaster more adhesive and flexible, whereas it was found to be too soft, and the Canada turpentine was irritant. The same end has been accomplished in the U. S. P. 1890 by the addition of olive oil. The use of ferric hydrate in the place of ferrous subcarbonate is an improvement, and in this respect the plaster is in accord with the British formula.

This preparation has enjoyed some popular celebrity, under the impression that it strengthens the parts to which it is applied; whence it has derived the name of strengthening plaster. It is used in those conditions of the loins, larger muscles, and joints which, though usually ascribed to debility, are in fact most frequently dependent on rheumatic or other chronic inflammatory affections, and, if relieved by the plaster, are so in consequence of the gentle excitation produced by it in the vessels of the skin, or of the exclusion of the air. It may also, in some instances, give relief by affording mechanical support; but neither in this nor in any other respect can it be deemed very efficient, because the ingredients composing it have no useful properties that are capable of being taken up by the absorbents.

EMPLASTRUM HYDRARGYRI. U. S., Br. Mercurial Plaster.

(ĘM-PLĂS'TRŲM HŸ-DRÄR'ĢŶ-RĪ.)

Emplastrum Mercuriale; Emplâtre mercuriel, *Fr.;* Quecksilber-Pflaster, *G.*

"Mercury, *three hundred grammes* [or 10 ounces av., 254 grains]; Oleate of Mercury, *twelve grammes* [or 185 grains]; Lead Plaster, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Triturate the Mercury with the Oleate of Mercury in a tared capsule until globules of metal are no longer visible. Then place the capsule on a water-bath, add enough Lead Plaster, previously melted, to make the contents weigh *one thousand grammes* [or 35 ounces av., 120 grains], and mix the whole thoroughly." *U. S.*

"Mercury, 3 *ounces* (Imperial) or 82 grammes; Olive Oil, 56 *grains* (Imp.) or 3·5 grammes; Sublimed Sulphur, 8 *grains* (Imp.) or 0·5 gramme; Lead Plaster, 6 *ounces* (Imp.) or 164 grammes. Heat the Olive Oil; add the Sulphur to it gradually; stir until they are uniformly blended; with this mixture triturate the Mercury until metallic globules are no longer visible; add the Lead Plaster previously melted; mix." *Br.*

The present official process differs from that of the U. S. Pharm. 1880 in employing oleate of mercury for the purpose of extinguishing the mercury; this it does effectually, and at the same time increases the efficiency of the mercurial constituent. The quantity of mercury is 30 per cent. The British preparation is stronger, containing nearly 50 per cent.

The U. S. and former British processes may be considered identical in their results. The sulphuretted oil which was employed in the process of the London College to facilitate the extinguishment of the mercury was abandoned in the first British Pharmacopœia, as just in proportion to the increased facility of the process it lessened the efficacy of the resulting plaster, mercury sulphide being wholly inert. Nevertheless, the Br. Pharmacopœia has in its last revision retained the old London formula. Mr. Thomas Blunt has found it almost impossible to divide the mercury sufficiently by trituration with oil and resin, and the resulting plaster was so crumbly that it could not be formed into rolls; but on substituting a weight of Venice turpentine equal to that of the oil and resin combined, he found it to answer completely. An objection, however, to the turpentine is, that it might render the plaster too irritant for susceptible skins. (*P. J. Tr.*, 1864, p. 56.)

This plaster is employed to produce the local effects of mercury upon venereal *buboes*, *nodes*, and other chronic tumefactions of the bones or soft parts, dependent on a syphilitic taint. In these cases it sometimes acts as a powerful discutient. It is frequently also applied to the side in *chronic hepatitis* or *splenitis*. In peculiarly susceptible persons it occasionally affects the gums.

From observations made in France by M. Serres and others, it appears that the mercurial plaster of the Codex (*Emplastrum de Vigo cum Mercurio*) has the power, when applied over the eruption of small-pox, before the end of the third day from its first appearance, to check its progress and prevent suppuration and pitting. This operation of the plaster, so far from being attended with an increase of the general symptoms, seems to relieve them in proportion to the diminution of the local affection. It is also thought that the course of the disease is favorably modified when the mercurial impression is produced upon the system. That the local effect is not ascribable to the mere exclusion of the air is proved by the fact that the use of lead plaster was not followed by the same results. It is probable that other mercurial preparations would answer the same purpose; and the common mercurial ointment has, in our own hands, proved effectual in rendering the eruption upon the face to a considerable extent abortive, in one bad case of small-pox. But, as the most successful results were obtained with the plaster above mentioned, we give in a foot-note the formula of the French Codex.*

EMPLASTRUM ICHTHYOCOLLÆ. U. S. Isinglass Plaster. [Court Plaster.]

(ĘM-PLĂS'TRŲM ĬĢH-THŸ-Ǫ-CŎL'LÆ.)

"Isinglass, *ten grammes* [or 154 grains]; Alcohol, *forty grammes* [or 1 ounce av., 180 grains]; Glycerin, *one gramme* [or 15½ grains]; Water, Tincture of Benzoin, each, *a sufficient quantity*.

* *Emplastrum de Vigo cum Mercurio.* "Take of simple plaster [lead plaster] *forty ounces;* yellow wax *two ounces;* resin *two ounces;* ammoniac, bdellium, olibanum, and myrrh, each, *five drachms;* saffron *three drachms;* mercury *twelve ounces;* turpentine [common European] *two ounces;* liquid storax *six ounces;* oil of lavender *two drachms.* Powder the gum-resins and saffron, and rub the mercury with the storax and turpentine in an iron mortar until completely extinguished. Melt the plaster with the wax and resin, and add to the mixture the powders and volatile oil. When the plaster shall have been cooled, but while it is yet liquid, add the mercurial mixture, and incorporate the whole thoroughly." This should be spread upon leather or linen cloths, and applied so as effectually to cover the part to be protected.

Dissolve the Isinglass in a sufficient quantity of hot Water to make the solution weigh *one hundred and twenty grammes* [or 4 ounces av., 102 grains]. Spread one-half of this, in successive layers, upon taffeta (stretched on a frame), by means of a brush, waiting after each application until the layer is dry. Mix the second half of the Isinglass solution with the Alcohol and Glycerin, and apply it in the same manner. Then reverse the taffeta, coat it on the back with Tincture of Benzoin, and allow it to become perfectly dry. Cut the plaster in pieces of suitable length and preserve them in well-closed vessels. The above-directed quantities are sufficient to cover a piece of taffeta *thirty-eight centimeters* [or about 15 inches] square." *U. S.*

This official preparation will probably be seldom made by the pharmacist. The introduction of a formula will, however, be of service by indicating the manner in which isinglass plaster can be made by those who desire to furnish a good preparation. The addition of glycerin prevents it from becoming brittle, and the tincture of benzoin is intended to render it water-proof. This it only partially accomplishes. Castor oil and weak collodion have been used instead with better results.

EMPLASTRUM MENTHOL. Br. Menthol Plaster.

(ĘM-PLĂS'TRUM MĔN'THŎL.)

"Menthol, 1½ *ounces* (Imperial) or 30 grammes; Yellow Beeswax, 1 *ounce* (Imp.) or 20 grammes; Resin, 7½ *ounces* (Imp.) or 150 grammes. Melt the Beeswax and Resin together; when the mixture approaches the temperature of 160° or 170° F. (71·1° or 76·7° C.), stir in the Menthol until dissolved." *Br.*

This is an official plaster of the British Pharmacopœia, having been introduced in the additions in 1885; the present plaster is, however, 5 per cent. weaker in menthol than that formerly official. It is a mild counter-irritant, intended especially for relief in localized *neuralgia* and *rheumatic pains.*

EMPLASTRUM OPII. U. S., Br. Opium Plaster.

(ĘM-PLĂS'TRUM Ō'PĮ-Ī.)

Emplastrum Opiatum, *P. G.;* Emplastrum Cephalicum, s. Odontalgicum; Emplâtre d'Opium, Emplâtre céphalique (temporal, odontalgique, calmant), *Fr.;* Opiumpflaster, Hauptpflaster, *G.*

"Extract of Opium, *sixty grammes* [or 2 ounces av., 51 grains]; Burgundy Pitch, *one hundred and eighty grammes* [or 6 ounces av., 153 grains]; Lead Plaster, *seven hundred and sixty grammes* [or 26 ounces av., 353 grains]; Water, *eighty cubic centimeters* [or 2 fluidounces, 338 minims], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Rub the Extract of Opium with the Water, until it is uniformly soft, and add it to the Burgundy Pitch and Lead Plaster melted together by means of a water-bath; then continue the heat for a short time, stirring constantly, until the moisture is evaporated." *U. S.*

"Opium, in very fine powder, 1 *ounce* (Imperial) or 10 grammes; Resin Plaster, 9 *ounces* (Imp.) or 90 grammes. Melt the Resin Plaster on a water-bath; stir in the Opium gradually." *Br.*

We decidedly prefer the extract of opium, as employed in the present U. S. process, to the opium itself of the British formula. It not only forms a better plaster, but, being soluble, is more likely to produce the anodyne effect desired, by being brought by the perspiration to the liquid state necessary for its absorption. The use of water in the former process is also an advantage, as it enables the opium to be more thoroughly incorporated with the other ingredients; but care should be taken that the moisture be well evaporated. The opium plaster is intended to relieve rheumatic and other pains in the parts to which it is applied.

EMPLASTRUM PICIS. Br. Pitch Plaster.

(ĘM-PLĂS'TRUM PĪ'CĬS.)

"Burgundy Pitch, 26 *ounces* (Imperial) or 520 grammes; Frankincense [Terebinthina, U. S.], 13 *ounces* (Imp.) or 260 grammes; Resin, 4½ *ounces* (Imp.) or 90 grammes; Yellow Beeswax, 4½ *ounces* (Imp.) or 90 grammes; Olive Oil, 2 *ounces* (Imp.) or 40 grammes; Distilled Water, 2 *fl. ounces* (Imp. meas.) or 40 cubic centimetres. Add the Olive Oil and the Water to the Frankincense, Burgundy Pitch, Resin, and Beeswax, previously melted together; evaporate with constant stirring to a proper consistence." *Br.*

This is a rubefacient plaster, which closely resembles the Burgundy pitch plaster of the U. S. P. 1890. (See the next article). The expressed oil of nutmeg directed in the Br. Pharm. of 1885 was not retained in the present British authority; it is an unnecessary addition. It

is applicable to catarrhal and other pectoral affections, chronic inflammation of the liver, and rheumatic pains in the joints and muscles. It often keeps up a serous discharge, which requires that it should be frequently renewed. The irritation which it sometimes excites is so great as to render its removal necessary.

EMPLASTRUM PICIS BURGUNDICÆ. U. S. Burgundy Pitch Plaster.

(ĘM-PLĂS'TRUM PĪ'CĬS BÜR-GŬN'DI-ÇÆ.)

Emplastrum Picatum, *F. P.;* Emplâtre de Poix de Bourgogne, *Fr.;* Burgunder Pech-Pflaster, *G.*

"Burgundy Pitch, *eight hundred grammes* [or 28 ounces av., 96 grains]; Olive Oil, *fifty grammes* [or 1 ounce av., 334 grains]; Yellow Wax, *one hundred and fifty grammes* [or 5 ounces av., 127 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt together the Burgundy Pitch and Yellow Wax, then incorporate the Olive Oil, and stir constantly, until the mass thickens on cooling." *U. S.*

In the former revision of the Pharmacopœia the quantity of wax in this plaster was diminished 3 per cent. This was done to round up the formula, but was undoubtedly a step in the wrong direction. The U. S. Pharmacopœia 1890 process makes a better plaster: 15 per cent. of wax has been directed instead of 10, whilst the addition of 5 per cent. of olive oil still further improves it. The object of the wax and olive oil is to give a proper consistence to the Burgundy pitch, and to prevent its great tendency to become brittle. M. Lavigne proposes to obviate the tendency of Burgundy pitch plaster to crack by incorporating with it caoutchouc, in the following method. Soften 35 parts, by weight, of caoutchouc, in small pieces, by warming it with 13 parts of petroleum in a close vessel. Melt together 300 parts of Burgundy pitch and 25 parts of white wax. Warm the solution of caoutchouc in a suitable vessel, add gradually, with constant stirring, the melted pitch and wax, and finally incorporate thoroughly with the mass 3 parts of glycerin. (*Journ. de Pharm.*, 4e sér., ix. 131.)

EMPLASTRUM PICIS CANTHARIDATUM. U. S. (Br.) Cantharidal Pitch Plaster. [Warming Plaster.]

(ĘM-PLĂS'TRUM PĪ'CĬS CĄN-THĂR-I-DĀ'TŬM.)

Emplastrum Calefaciens, *Br.;* Warm Plaster; Emplâtre de Poix cantharidé, *Fr.;* Pechpflaster mit Canthariden, *G.*

"Cerate of Cantharides, *eighty grammes* [or 2 ounces av., 359 grains]; Burgundy Pitch, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Cerate of Cantharides on a water-bath containing boiling water, and continue the heat for fifteen minutes; then strain it through a piece of muslin of close texture so that the Cantharides will be retained on the muslin. To the strained liquid add a sufficient quantity of Burgundy Pitch to make the whole weigh *one thousand grammes* [or 35 ounces av., 120 grains], render the mixture homogeneous by stirring, remove the heat, and stir the mass until it thickens on cooling." *U. S.*

"Cantharides, in coarse powder, 4 *ounces* (Imperial) or 100 grammes; Yellow Beeswax, 4 *ounces* (Imp.) or 100 grammes; Resin, 4 *ounces* (Imp.) or 100 grammes; Resin Plaster, 3¼ *pounds* (Imp.) or 1300 grammes; Soap Plaster, 2 *pounds* (Imp.) or 800 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 500 cubic centimetres. Infuse the Cantharides in the Distilled Water for six hours; squeeze strongly through calico; evaporate the expressed liquid on a water-bath till reduced to one-third; add the other ingredients; melt on a water-bath; stir until the ingredients are thoroughly mixed." *Br.*

This plaster is an excellent rubefacient, more active than Burgundy pitch, yet in general not sufficiently so to produce vesication. As prepared by the U. S. 1870 process it occasionally blistered; and the proportion of cantharides was, therefore, considerably diminished in the U. S. 1880 and 1890 formulas. This is unfortunate; for, while such a reduction may render the plaster insufficiently active in most cases, it does not entirely obviate the objection, as the smallest proportion of flies, or even the Burgundy pitch alone, would vesicate in certain persons. In whatever mode, therefore, this plaster may be prepared, it cannot always answer the expectations which may be entertained; and the only plan, when the skin of any individual has been found to be very susceptible, is to accommodate the proportions to the particular circumstances of the case. Much, however, may be accomplished by care in the preparation of the plaster, towards obviating its tendency to blister. If the flies of the *Ceratum Cantharidis* have been coarsely pulverized, the latter particles, coming in contact with the skin, will exert upon the particular part to which they may be applied their full vesicatory effect, while if reduced to a

very fine powder they would be more thoroughly enveloped in the other ingredients, and thus have their strength much diluted. Hence the cerate when used as an ingredient of the warming plaster should contain the cantharides as minutely divided as possible; and the direction given in the U. S. 1890 process to strain it through cloth of fine texture should be carefully observed. The plan of keeping the cerate used in this preparation for a considerable time at the temperature of 100° C. (212° F.), and then straining it so as to separate the flies, is a good one, but it would be better yet to substitute cerate *of the extract* of cantharides for the cerate of cantharides. (See *Ceratum Cantharidis.*) The mode frequently pursued of preparing the warming plaster by simply sprinkling a very small proportion of powdered flies upon the surface of Burgundy pitch is altogether objectionable. It has been objected to the U. S. plaster that it is apt to be too soft in hot weather. Mr. G. C. Close, ascribing this inconvenience to the proportion of lard in the cerate employed, proposes to obviate it by substituting Burgundy pitch plaster for Burgundy pitch, and powdered cantharides for the cerate, and offers a formula in accordance with this suggestion. (See *A. J. P.*, 1867, p. 20; from *Proc. A. P. A.*, 1866.)

The warming plaster is employed in *chronic rheumatism*, and in chronic internal diseases attended with inflammation or an inflammatory tendency, such as *catarrh*, *asthma*, *pertussis*, *phthisis*, *hepatitis*, and the sequelæ of *pleurisy* and *pneumonia*.

EMPLASTRUM PLUMBI. U. S., Br. Lead Plaster. [Diachylon Plaster.]

(ĘM-PLĂS'TRŬM PLŬM'BĪ.)

Emplastrum Lithargyri, *Br.* 1864; Emplastrum Lithargyri Simplex, *P. G.;* Emplastrum Simplex, *F. P.;* Emplastrum Diachylon Simplex, Emplastrum Album Coctum; Litharge Plaster; Emplâtre simple, Emplâtre de Plomb (de Litharge), *Fr.;* Emplastrum Cerusæ, Froschlaichpflaster, Bleipflaster, Diachylon-Pflaster, *G.*

"Lead Oxide, *three thousand two hundred grammes* [or 112 ounces av., 383 grains]; Olive Oil, *six thousand grammes* [or 211 ounces av., 282 grains]; Water, *a sufficient quantity.* Mix the Lead Oxide, previously passed through a No. 80 sieve, intimately with about one-half of the Olive Oil, by trituration, and add the mixture to the remainder of the Oil contained in a bright copper boiler of a capacity equal to at least four times the bulk of the ingredients. Then add *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of boiling Water, and boil the whole together, over a fire, constantly stirring with a wooden spatula, until a small portion, when dropped into cold water, is found to be pliable and tenacious. From time to time add a little Water to replace that lost by evaporation. When the contents of the boiler have acquired a whitish color and are perfectly homogeneous, transfer them to a vessel containing warm Water, and as soon as the mass has sufficiently cooled, knead it well with the Water so as to remove the glycerin, renewing the Water from time to time, as long as it may be necessary. Finally divide the mass into rolls of suitable size." *U. S.*

"Lead Oxide, 1 *pound* (Imperial) or 400 grammes; Olive Oil, 2 *pounds* (Imp.) or 800 grammes; Distilled Water, 16 *fl. ounces* (Imp. meas.) or 400 cubic centimetres or a sufficient quantity. Boil all the ingredients together gently by the aid of a steam-bath; keep them simmering for four or five hours, stirring constantly until the product acquires a proper consistence for a plaster; add more of the Distilled Water during the process if necessary." *Br.*

The importance of this plaster, as the basis of most of the others, requires a somewhat detailed account of the principles and manner of its preparation. An improvement will be observed in the U. S. P. 1890 process for this plaster in the washing out of the glycerin and the subsequent separation of the liquids by kneading the plaster.

A reaction takes place between the oil and water, resulting in the development of *glycerin*, and of two acid bodies, *oleic* and *palmitic acids*, to which, when animal fat is employed instead of olive oil, a third is added,—namely, *stearic acid.* The plaster is formed by a union of these acids with the oxide, and, prepared according to the directions of the Pharmacopœias, is in fact a lead oleo-palmitate, and if the olive oil contained stearin it would be a lead oleo-stearo-palmitate. The glycerin remains dissolved in the water, or mechanically mixed with the plaster. That such is the correct view of the nature of this compound is evinced by the fact that, if the lead oxide be separated from the plaster by digestion at a moderate heat in very dilute nitric acid, the fatty matter which remains will unite with litharge with the greatest facility, without the intervention of water. According to the modern chemical views, the fixed or fatty oils are compounds of the free fatty acids mentioned and the radical *glyceryl.* When boiled with the lead oxide and water, the fatty acids combine with the metallic oxide to form the plaster, and the glyceryl unites with the liberated hydrogen and becomes glycerin.

The reaction for olein and lead oxide is as follows: $\underset{\text{olein}}{2C_3H_5(C_{18}H_{33}O_2)_3} + \underset{\text{litharge}}{3PbO} + \underset{\text{water}}{3H_2O} = \underset{\text{lead oleate}}{3Pb(C_{18}H_{33}O_2)_2} + \underset{\text{glycerin}}{2C_3H_5(OH)_3}$. The radical glyceryl ($C_3H_5$) is a triad, and combines with three groups of a fatty acid or three groups of hydroxyl (OH).

Other oleaginous substances and other metallic oxides are susceptible of the same combination, and some of them form compounds having the consistence of a plaster; but, according to M. Henry, of Paris, no oily matter except animal fat can properly be substituted for olive oil, and no metallic oxide, not even one of the other oxides of lead, for litharge. He ascertained, moreover, that the English litharge is preferable for the formation of lead plaster to the German. From more recent experiments of Soubeiran, it appears that massicot or even minium may be substituted for litharge, and a plaster of good consistence be obtained, but that a much longer time is required for completing the process than when the official formula is followed. Owing to the necessity for its partial deoxidation, the use of minium requires a longer continuance of the process than when massicot is employed. According to M. Davallon, Professor in the School of Medicine and Pharmacy at Lyons, it is important that the olive oil employed should be pure; for when adulterated, as it frequently is, it yields an imperfect product. Mr. N. S. Thomas prepared a good plaster by substituting lard for olive oil, in the proportion of eight pounds of lard to five of litharge (*A. J. P.*, xix. 175); and we are told that it is a common practice in this country to make lead plaster with a mixture of lard oil and olive oil. Mueller uses equal parts of lard, olive oil, and litharge, having previously heated the litharge until a small sample causes no effervescence when dropped into nitric acid, showing the absence of carbonate. (*Pharm. Ztg.*, 1879, p. 70; *A. J. P.*, 1879, p. 190.) It is said that the English plaster-makers rarely follow the Br. Pharm. direction, preferring the recipe of the old London Pharmacopœia, which contains more litharge and yields a much firmer and less adhesive product.* (*P. J. Tr.*, 3d ser., v. 701, 716.) Lead plaster has also been prepared by double decomposition between soap and lead acetate or subacetate; but the results have not been so advantageous as to lead to the general adoption of this process. (See *A. J. P.*, ix. 727, and *Journ. de Pharm.*, xxiii. 163 and 322.)†

Preparation. The vessel in which the lead plaster is prepared should be of such a size that the materials will not occupy more than two-thirds of its capacity.‡ The oil should be first introduced, and the litharge then sprinkled in by means of a sieve, the mixture being constantly stirred with a spatula. The particles of the oxide are thus prevented from coalescing in small masses, which the oil would not easily penetrate, and which would therefore delay the process. While the water exerts an important chemical agency in the changes which occur, it is also useful by preventing too high a temperature, which would decompose the oil, and cause the reduction of the oxide. The waste must, therefore, be supplied by fresh additions as directed in the process; and the water added for this purpose should be previously heated, as otherwise it would not only delay the operation, but by producing explosion might endanger the operator. During the continuance of the boiling, the material should be constantly stirred, and the spatula should be repeatedly passed along the bottom of the vessel, from side to side, so as to prevent any of the oxide, which is disposed by its greater density to sink to the bottom, from remaining in that situation. The materials swell up considerably, in consequence partly of the vaporization of the water, partly of the escape of carbonic acid gas, which is liberated by the oily acids from some lead carbonate usually contained in the litharge. The process should not be continued longer than is sufficient to produce complete union of the ingredients, and this may be known by the color and consistence of the mass. The color of the litharge gradually becomes paler, and at length almost white when the plaster is fully formed. The consistence increases with the progress of the boiling, and is sufficiently

* *Schwarze's Mutterpflaster, Emplastrum Fuscum* of the German Pharmacopœia, is made by boiling 64 parts of olive oil with 32 parts of very finely powdered red lead in a copper kettle until the mass is dark brown, and then adding 16 parts of yellow wax. *Emplastrum Fuscum Camphoratum* is the same, with the addition of 1 per cent. of camphor.

† *Zinc Plaster.* M. de Mussey, having witnessed inconveniences from lead plaster in consequence of the absorption of the lead, substituted for it a plaster with a basis of zinc oxide, which he has found to answer very well in practice. It cannot be made by direct combination of the oxide; and it is necessary to have recourse to the method of double decomposition. Solutions of white olive oil soap and of zinc sulphate being mixed, a copious precipitate takes place of zinc oleo-palmitate, which, after being washed and dried, may be combined with resins, oil, and wax, to give it the necessary consistence. (*Journ. de Pharm.*, xxvii. 100.)

‡ The method of triturating the litharge with a portion of the oil (see U. S. P. 1890 process above) is applicable to small operations, but will not be found necessary in making lead plaster on the scale usually employed by manufacturers.

thick when a portion of the plaster, taken out and allowed to cool upon the end of a spatula, or thrown into cold water, becomes solid, without adhering in this state to the fingers. The portion thus solidified should not present, when broken, any red points, which would indicate the presence of a portion of uncombined litharge. When the plaster is formed, it should be removed from the fire, and after a short time cold water should be poured upon it. Portions should then be detached from the mass, and, having been well kneaded under water, in order to separate the viscid solution of glycerin contained in the interior, should be formed into cylindrical rolls, and wrapped in paper. Such, at least, has been the course of proceeding usually recommended. But M. Davallon maintains that the presence of glycerin in the plaster is useful by keeping it in a plastic state, and that washing and kneading are injurious, the former by removing the glycerin, the latter by introducing particles of air and moisture into the mass, which is thus rendered more disposed to rancidity. (*A. J. P.*, xv. 274; from *Journ. de Chim. Méd.*) By employing steam heat in the preparation of this plaster, the risk of burning it is avoided. For a good arrangement for this purpose, see *Mohr and Redwood's Pharmacy*, edited by Prof. Procter, p. 420. Bernbeck found that lead plaster could be preserved from hardening and oxidation if kept in air-tight canisters. (*Pharm. Zeitung*, 1881, p. 589.)

Lead plaster is officially described as "a yellowish-white, pliable, and tenacious, but not greasy mass, gradually acquiring a brownish tint on the outside. On treating 5 Gm. of Lead Plaster with 25 C.c. of benzol, a somewhat viscid and slightly turbid solution will result, which will separate into a clear and gelatinous layer after some time, but which should not deposit any sediment (absence of *uncombined lead oxide*)." *U. S.*

Mr. C. Lewis Diehl found it almost impossible, in following the U. S. directions of 1860, to obtain a plaster wholly free from uncombined litharge. He obviated the difficulty by first rubbing the sifted litharge with about half its weight of oil, then stirring the mixture with the remainder of the oil, in a tinned copper kettle, adding the water, and heating to 212° F. until a uniform plaster was formed. (*A. J. P.*, 1867, p. 385.) Kremel states that when lead plaster is made from oleic acid, the product is almost entirely soluble in ether; when made with olive oil or lard, it contains lead stearate and palmitate, and thus a larger proportion is insoluble in ether. (*Archiv d. Pharm.*, 1887, p. 405.)

Medical Properties and Uses. This plaster, which has long been known under the name of *diachylon*, is used as an application to excoriated surfaces and to slight wounds, which it serves to protect from the action of the air. It may also be beneficial by the sedative influence of the lead which enters into its composition. A case is on record in which lead colic resulted from its long-continued application to a large ulcer of the leg. (*Am. Journ. of Med. Sci.*, xxiii. 246.) Dr. J. M. Bigelow reports a case of excessive sweating of the feet cured by putting the patient in bed for thirteen days and keeping the feet enveloped in strips of lead plaster. (*N. R.*, Oct. 1875.) Its chief use is in the preparation of other plasters.*

EMPLASTRUM PLUMBI IODIDI. Br. Lead Iodide Plaster.

(ĘM-PLĂS'TRŲM PLŬM'BĪ Ī-ŎD'Į-DĪ.)

Emplâtre d'Iodure de Plomb, *Fr.*; Jodblei-Pflaster, *G.*

"Lead Iodide, 2 *ounces* (Imperial) or 50 grammes; Lead Plaster, 1 *pound* (Imp.) or 400 grammes; Resin, 2 *ounces* (Imp.) or 50 grammes. Finely powder the Lead Iodide; mix it with the Lead Plaster and Resin previously melted together at as low a temperature as possible." *Br.*

This is a local discutient plaster, which may also be used with other means to affect the system. (See *Plumbi Iodidum.*)

* *Logan's Plaster.* Take of Litharge, Lead Carbonate, each, *a pound;* Castile Soap, *twelve ounces;* Butter (fresh), *four ounces;* Olive Oil, *two and a half pints;* Mastic, in powder, *two drachms.* It is to be understood that the pound and ounce are of the avoirdupois weight. Having mixed the Soap, Oil, and Butter, add the Litharge, and boil the mixture gently, constantly stirring, for an hour and a half, or until it shall assume a pale brown color; then increase the heat somewhat, and continue to boil, until a portion of the liquid, dropped on a smooth board, is found not to adhere to it on cooling; then remove it from the fire, and mix the Mastic with it. Logan's plaster has long been in popular use in Philadelphia, and is yet employed by regular practitioners as a protective and discutient application.

Plaster of Lead Carbonate. This was originally introduced into our Pharmacopœia as a substitute for *Mahy's plaster*, at one time much employed in some parts of the United States, but was omitted in the edition of 1840. It is a good application to surfaces inflamed or excoriated by friction, and may be resorted to with advantage in those troublesome cases of cutaneous irritation, and even ulceration, which are apt to occur upon the back and hips during long-continued confinement to one position. We give the process as contained in the Pharmacopœia of 1830. "Take of Carbonate of Lead *a pound;* Olive Oil *two pints;* Yellow Wax *four ounces;* Lead Plaster *a pound and a half;* Florentine Orris, in powder, *nine ounces.* Boil together the Oil and Carbonate of Lead, adding a little water and constantly stirring, till they are thoroughly incorporated; then add the Wax and Plaster, and, when these are melted, sprinkle in the Orris, and mix the whole together." By this process a good plaster may be prepared, rather too soft at first, but soon acquiring the proper consistence.

EMPLASTRUM RESINÆ. U. S., Br. Resin Plaster. [Adhesive Plaster.]

(ĘM-PLĂS'TRUM RĘ-ŞĪ'NÆ.)

Emplastrum Adhesivum, *P. G.;* Emplâtre résineux (adhésif), *Fr.;* Heftpflaster, *G.*

"Resin, in fine powder, *one hundred and forty grammes* [or 4 ounces av., 410 grains]; Lead Plaster, *eight hundred grammes* [or 28 ounces av., 96 grains]; Yellow Wax, *sixty grammes* [or 2 ounces av., 51 grains], To make *one thousand grammes* [or 35 ounces av., 120 grains]. Melt the Lead Plaster and Yellow Wax together with a gentle heat; then add the Resin, and, when it is melted, mix the mass thoroughly." *U. S.*

"Resin, 4 *ounces* (Imperial) or 100 grammes; Lead Plaster, 2 *pounds* (Imp.) or 800 grammes; Hard Soap, 2 *ounces* (Imp.) or 50 grammes. Melt each ingredient separately at as low a temperature as possible; mix." *Br.*

Resin plaster differs from the lead plaster in being more adhesive and somewhat more stimulating. It is the common adhesive plaster of commerce, and is much employed for retaining the sides of wounds in contact, and for dressing ulcers according to the method of Baynton, by which the edges are drawn towards each other and a firm support is given to the granulations. As prepared by the Dublin College it contained soap, which gave it greater pliability, and rendered it less liable to crack in cold weather, without impairing its adhesiveness; and the process of that College has been adopted in the British Pharmacopœia. It is usually spread upon muslin; and the spreading is best accomplished, on a large scale, by means of a machine, as described in the general observations upon plasters. It is kept ready spread by the pharmacist; but, as the plaster becomes less adhesive by long exposure to the air, the supply should be frequently renewed. When the skin is very delicate, it occasionally excites some irritation, and under these circumstances a plaster may be substituted containing a smaller proportion of resin. That originally employed by Baynton contained only six drachms of resin to the pound of lead plaster. To obviate the same evil, M. Herpin recommends the addition of lead tannate, the proportion of which, when adhesiveness is required in the plaster, should not exceed one-twentieth, but under other circumstances may be increased to one-twelfth. (*Bull. de Thérap.*, xlviii. 155.)

In order to render the plaster more adhesive, and less brittle in cold weather, it is customary with many manufacturers to employ a considerable proportion of Burgundy pitch or turpentine in its preparation; but these additions are objectionable, as they greatly increase the liability of the plaster to irritate the skin, and thus materially interfere with the purposes for which the preparation was chiefly intended.*

EMPLASTRUM SAPONIS. U. S., Br. Soap Plaster.

(ĘM-PLĂS'TRUM SĄ-PŌ'NĪS.)

Emplastrum Saponatum, *P. G.;* Emplastrum cum Sapone, *F. P.;* Emplâtre de Savon, *Fr.;* Seifenpflaster, *G.*

"Soap, dried and in coarse powder, *one hundred grammes* [or 3 ounces av., 230 grains]; Lead Plaster, *nine hundred grammes* [or 31 ounces av., 326 grains]; Water, *a sufficient quantity.* Rub the Soap with enough Water to reduce it to a semi-liquid state; then mix it with the Lead Plaster, previously melted, and evaporate to the proper consistence." *U. S.*

"Hard Soap, 6 *ounces* (Imperial) or 150 grammes; Lead Plaster, 2¼ *pounds* (Imp.) or 900 grammes; Resin, 1 *ounce* (Imp.) or 25 grammes. Melt each ingredient separately at a low temperature; mix; evaporate, with constant stirring, to a proper consistence." *Br.*

The present U. S. formula is an improvement upon that of a former edition of the Pharmacopœia. By directing the soap to be in powder instead of sliced, it may be more thoroughly incorporated with the plaster. Greater plasticity is accomplished, in some degree, in the British process by the resin. In preparing the U. S. plaster, Mr. C. Lewis Diehl has found some difficulty in rubbing the soap up perfectly and rapidly with the water, and has, therefore, adopted the plan of first rubbing the soap with its weight of water, then straining the mixture through coarse muslin, and lastly reducing the residue with a proportionate quantity of water, before stirring the whole into the melted plaster. (*A. J. P.*, 1867, p. 386.) Soap plaster is considered

* An adhesive plaster exempt from oxide of lead is prepared by Pettenkofer. It consists of calcareous soap incorporated with turpentine and suet, and may be prepared in the following manner. A solution of soap is decomposed by a solution of calcium chloride. The precipitate, having been expressed and dried, is powdered with half its weight of turpentine dried by heat; and the mixture is melted, along with an eighth part of suet, in boiling water. The mixture is boiled until the mass melts into a homogeneous fluid, when it is worked by the hand, in the ordinary manner, in cold water. Should portions of the calcareous soap not melt, they should be separated by straining through flannel. (*Journ. de Pharm.*, 3e sér., x. 358.)

discutient, and is sometimes used as an application to tumors, where a dressing is required. Somewhat softer in its character, the soap cerate,* formerly official, may be found useful.

EMULSA. Emulsions.

(Ē-MŬL'SĄ.)

Under this head are included in the Pharmacopœia of 1890 liquid preparations in which oleaginous substances are suspended in watery fluids by the intervention of gum, the yolk of egg, or other viscid matter. The preparations forming the present class of emulsions were termed Mixtures in former pharmacopœias, and it is to be regretted that under this indefinite term are still grouped liquids of many kinds: the separation of these into proper classes is only a question of time, and the introduction of this new class into the Pharmacopœia of 1890 marks the first step in the direction of greater accuracy in defining pharmaceutical preparations, and more system in classification. The object of emulsions is usually to facilitate the administration, to conceal the taste, or to obviate the nauseating effects of unpleasant medicines; and their perfection depends upon the intimacy with which the ingredients are blended. Some skill and care are requisite for the production of uniform and perfect emulsions. As a rule, the body to be suspended should be thoroughly mixed by trituration with the substance intended to act as the intermedium, before the watery vehicle is added. In the case of the liquid balsams and oils, if gum arabic be employed as the intermedium it should be previously brought to the state of mucilage of the consistence directed in the U. S. Pharmacopœia. When a fixed oil or balsam is to be made into an emulsion, the method most employed abroad is to add one part of gum to two or three of the oil, in a mortar, triturate until the mixture is complete, and then add at once twice as much water as gum used, and triturate rapidly until the oil is completely emulsified, then gradually add the remainder of the vehicle with constant trituration. Agitation in a bottle is sometimes substituted for trituration. The plan most largely used in this country is to make the emulsion with mucilage. Having a broad flat pestle and a mortar perfectly free from grease, put in a little mucilage, rub it around the mortar, add about half as much oil, triturate from the centre so as to emulsify this, then add more mucilage, then oil, and so on until the operation is completed. Care is required never to get the oil in excess of the mucilage. This plan seems to accord with the principle laid down by R. Rother (*Chicago Pharmacist*, 1872, p. 25), that the most perfect and rapid emulsifier is a perfect emulsion. The proportion of gum and water necessary to make a good emulsion with the fixed oils varies with the oil. Thus, while castor oil requires only two drachms of the gum and three drachms of water to the ounce, most other fixed oils require half their weight of gum, and a weight of water equal to half that of the oil and gum united. These quantities being well rubbed together, any desirable amount of water may afterwards be gradually added, and will readily incorporate with the other ingredients. The white of egg has been frequently ordered by physicians as the suspending substance; but it is inferior for this purpose to the yolk, or to gum arabic. When the white is used it should be well beaten, and incorporated with the oleaginous or balsamic substances before the water is added. Quillaja, saponin, and other substances having similar properties have been proposed as emulsifying agents, but they are objectionable on account of their physiological activity. Emulsifying agents should be inert.

EMULSUM AMMONIACI. U. S. (Br.) Emulsion of Ammoniac.

[Mistura Ammoniaci, Pharm. 1880.]

(Ē-MŬL'SŬM ĂM-MŌ-NĪ'Ą-CĪ.)

Mistura Ammoniaci, *Br.;* Ammoniac Mixture; Emulsio Ammoniaci, Lac Ammoniaci; Ammoniacum Mixture, Milk of Ammoniac; Mixture de Gomme ammoniaque, Lait ammoniacal, *Fr.;* Ammoniak-Emulsion, *G.*

"Ammoniac, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the Ammoniac, in a warmed mortar, with *nine hundred cubic centimeters* [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Ammoniacum, in coarse powder, ¼ *ounce* (Imperial) or 5 grammes; Syrup of Tolu, 4 *fl. drachms* (Imp. meas.) or 10 cubic centimetres; Distilled water, 7½ *fl. ounces* (Imp. meas.) or 150

* *Ceratum Saponis.* U. S. 1870. *Soap Cerate.* (Cérat de Savon, *Fr.;* Seifencerat, *G.*) "Take of Soap Plaster *two troyounces;* White Wax *two troyounces and a half;* Olive Oil *four troyounces.* Melt together the Plaster and Wax, add the Oil, and, after continuing the heat a short time, stir the mixture until cool." *U. S.* 1870.

Soap cerate is thought to be cooling and sedative, and is used in scrofulous swellings and other instances of chronic external inflammation.

cubic centimetres. Triturate the Ammoniacum thoroughly with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water and the Syrup of Tolu, triturating until the mixture assumes a uniform milky appearance; strain through muslin." *Br.*

In this emulsion the resinous and oily constituents are suspended by means of the gum of the ammoniac, imparting a milky appearance to the preparation, which from this circumstance was formerly called *lac ammoniaci*, or *milk of ammoniac*. The greater portion of the resin subsides upon standing. The British Pharmacopœia (1898) process directs the addition of a small quantity of syrup of Tolu, doubtless as a flavoring agent. The emulsion is slightly curdled by acids. The dose is from one to two tablespoonfuls (15 to 30 C.c.).

EMULSUM AMYGDALÆ. U. S. (Br.) Emulsion of Almond.

[Mistura Amygdalæ, Pharm. 1880. Milk of Almond.]

(Ē-MŬL'SŬM Ą-MĬG'DĄ-LÆ.)

Mistura Amygdalæ, *Br.;* Almond Mixture; Emulsio Amygdalæ, s. Amygdalarum, Emulsio Simplex; Milk of Almonds, Simple Emulsion; Lait d'Amandes, *Fr.;* Mandelemulsion, Mandelmilch, *G.*

"Sweet Almond, *sixty grammes* [or 2 ounces av., 51 grains]; Acacia, in fine powder, *ten grammes* [or 154 grains]; Sugar, *thirty grammes* [or 1 ounce av., 25 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Having blanched the Almond, add the Acacia and Sugar, and beat them, in a mortar, until they are thoroughly mixed. Then rub the mass with *nine hundred cubic centimeters* [or 30 fluidounces] of Water, at first very gradually added, until a uniform mixture results. Strain this into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." *U. S.*

"Compound Powder of Almonds, 2 *ounces* (Imperial) or 20 grammes; Distilled Water, 16 *fl. ounces* (Imp. meas.) or 160 cubic centimetres. Triturate the Powder with a little of the Distilled Water so as to form a thin paste; gradually add the remainder of the Distilled Water; strain through fine muslin." *Br.*

These preparations are essentially the same, the gum and sugar which enter into the U. S. formula directly being ingredients of the compound powder of almonds of the British. The gum arabic in these formulas is introduced not so much for its demulcent properties as to assist in the suspension of the insoluble ingredients of the almonds. The same formula will answer for the preparation of an *emulsion of bitter almonds*. The oleaginous matter of the almonds is suspended in the water by means of their albumen, gum, and sugar, forming a milky emulsion. When the almonds themselves are employed, as in the U. S. process, care should be taken to reduce them to the consistence of a paste previously to the addition of the water; and with each successive portion of fluid a uniform mixture should be formed before another portion is added. Common water, when pure, may be properly substituted for the distilled. Great care should be taken to select the almonds perfectly free from rancidity. The emulsion is not permanent.* Upon standing, the oil rises like thick cream to the surface, and the separation is effected more quickly by heat, alcohol, and the acids, which coagulate the albumen. The preparation is closely analogous to milk in chemical relations and appearance. In warm weather it soon becomes sour.

Emulsion of almond has a bland taste, and may be used as an agreeable, nutritive demulcent in catarrhal and dysenteric affections and irritation of the urinary passages. To be of service it must be freely employed. From two to eight fluidounces (60 to 236 C.c.) may be taken at once. It is occasionally employed as the vehicle of less agreeable medicines, but should not be used with any considerable quantity of tinctures, acidulous salts, or other acid substances.

EMULSUM ASAFŒTIDÆ. U. S. Emulsion of Asafetida. [Mistura Asafœtidæ, Pharm. 1880. Milk of Asafœtida.]

(Ē-MŬL'SŬM ĂS-Ą-FŒT'Ĭ-DÆ—ăs-ą-fĕt'ĭ-dē.)

Asafetida Mixture; Mistura (Lac) Asafœtidæ; Mixture (Lait) d'Asafœtida, *Fr.;* Asafœtida-Emulsion, Stinkasantmilch, *G.*

"Asafetida, in selected tears, *forty grammes* [or 1 ounce av., 180 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Rub the

* *Concentrated Emulsion of Almonds.* H. P. Reynolds prepares a permanent preparation which, when mixed with three times its bulk of water, makes an emulsion which cannot be distinguished from the official, by using the following formula. Take of Sweet Almonds [blanched], Sugar, Glycerin ("C. P."), each, one ounce; Powdered Gum Arabic one drachm; Water two ounces. Rub to a uniform paste, strain through muslin, evaporate by a heat not exceeding 150° F. to the consistency of a fresh solid extract, flavor to suit.

Asafetida, in a warmed mortar, with *nine hundred cubic centimeters* [or 30 fluidounces] of Water, at first very gradually added, until a uniform emulsion results. Then strain the mixture into a graduated vessel, and wash the mortar and strainer with enough Water to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the whole thoroughly." *U. S.*

The present 4-per-cent. official emulsion slightly exceeds in strength the mixture of the U. S. P. 1870, which contained but 3 per cent. of asafetida. This emulsion is less stimulant than the tincture, and more prompt in its action than the pill. Its excessively disagreeable smell and taste are, however, objections, which induce a frequent preference for the last-mentioned preparation. It is very often employed as an enema. The dose is from one to two tablespoonfuls (15 to 30 C.c.), frequently repeated. From two to four fluidounces (60 to 118 C.c.) may be given by the rectum. Mr. D. Ackerman prepares a concentrated emulsion of asafetida, which will keep if excluded from the light, by using a mixture of three-fourths of pure water and one-fourth of dilute acetic acid as the menstruum. For cleaning mortars in which asafetida has been rubbed, he recommends liquor potassæ, followed by bitter almond water or paste, and soap and water. (*A. J. P.*, 1874, p. 268.)

EMULSUM CHLOROFORMI. U. S. Emulsion of Chloroform. [Mistura Chloroformi, Pharm. 1880.]

(Ē-MŬL'SŬM ØHLŌ-RŌ-FÖR'MĪ.)

Chloroform Mixture; Emulsio Chloroformi; Emulsion de Chloroforme, *Fr.;* Chloroform-Emulsion, *G.*

"Chloroform, *forty cubic centimeters* [or 1 fluidounce, 170 minims]; Expressed Oil of Almond, *sixty cubic centimeters* [or 2 fluidounces, 14 minims]; Tragacanth, in very fine powder, *fifteen grammes* [or 231 grains]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Introduce the Tragacanth into a perfectly dry bottle of sufficient capacity, add the Chloroform, and shake the bottle thoroughly, so that every part of the surface may become wetted. Then add about *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and incorporate it by vigorous shaking. Next add the Expressed Oil of Almond, in several portions, shaking after each addition, and when the Oil has been thoroughly emulsified, add enough Water, in divided portions, shaking after each addition, until the product measures *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.* The chloroform mixture of the U. S. P. 1880* was an excellent preparation; the new emulsion is not quite identical, there being no camphor in it. The expressed oil of almond renders the emulsion more permanent; and the proportion of chloroform is slightly less than in the U. S. P. 1880 chloroform mixture, being 4 per cent. instead of 5 per cent. as formerly. This emulsion affords an easy and agreeable method of administering chloroform; the emulsion is permanent and does not separate on standing. The chloroform makes it keep long unchanged. Dose, one or two tablespoonfuls (15 or 30 C.c.).

ERGOTA. U. S., Br. Ergot. [Ergot of Rye.]

(ĔR'GŌ-TĂ.)

"The sclerotium of Claviceps purpurea (Fries), Tulasne (class, Fungi), replacing the grain of rye, Secale cereale, Linné (nat. ord. Gramineæ). Ergot should be only moderately dried. It should be preserved in a close vessel, and a few drops of chloroform should be dropped upon it from time to time to prevent the development of insects. When more than one year old, it is unfit for use." *U. S.* "The sclerotium of Claviceps purpurea, Tulasne, originating in the ovary of Secale cereale, Linn." *Br.*

Secale Cornutum, *P. G.;* Secale Clavatum, Mater Secalis, Clavus Secalinus; Spurred Rye; Ergot, Seigle ergoté (noir), Blé cornu, *Fr.;* Mutterkorn, Kornmutter, Lapfenkorn, *G.*

In all the Gramineæ, or grass tribe, and in some of the Cyperaceæ, the place of the seeds is sometimes occupied by a morbid growth which, from its resemblance to the spur of a cock, has received the name of *ergot*, adopted from the French. This product is most frequent in the rye, *Secale cereale*, and from that grain was adopted in the first edition of the U. S. Pharmacopœia, under the name of *secale cornutum*, or *spurred rye*. In the edition of 1840 the name was changed to *ergota*. It is probable that this morbid growth has similar properties from whatever plant derived; and the fact has been proved in relation to the ergot of wheat.

* "Purified Chloroform, *eight parts* [or two fluidrachms]; Camphor, *two parts* [or forty-five grains]; Fresh Yolk of Egg, *ten parts* [or half a fluidounce]; Water, *eighty parts* [or four fluidounces], To make *one hundred parts* [or about five fluidounces]. Rub the Yolk of Egg in a mortar, first by itself, then with the Camphor, previously dissolved in the Chloroform, and lastly, with the Water, gradually added, so as to make a uniform mixture." *U. S.*

(See *Am. Journ. Med. Sci.*, N. S., xxxii. 479.) Indeed, in a case reported by Dr. D. L. McGugin (*Iowa Med. Journ.*, iv. 93), this variety of ergot is said to have succeeded promptly when that of rye, previously tried, had failed.* A short thick ergot produced upon the wild rice of Minnesota is said to be used as an abortifacient and during labor by the Indian women.† M. Leperdriel, Jr., of Montpellier, in France, affirms that the *ergot of wheat* is destitute of the poisonous properties of that of rye, and is less liable to change. The former point is, to say the least, very uncertain. Prof. Bentley, of London, found that of two specimens, one of the ergot of rye, the other of wheat, which had been kept under similar circumstances for ten years, the former was quite destroyed, while the latter was apparently unchanged. Ergot is rarer in wheat than in rye; and in the head of the former there is generally but one and very rarely more than two of the diseased grains. It is produced usually in wheat in wet seasons, and on that side of the head most exposed to the dampness. It is shorter and much thicker than the ergot of rye, being about half an inch long and three-quarters of an inch or more in circumference, and cleft into two or three divisions. In color and smell it resembles the spurred rye. (*P. J. Tr.*, March and April, 1863.)

Ergot. *A*, head of rye with ergot (*a*) growing in it; *B*, young ergot, showing the growing sclerotium carrying upon its top the old diseased ovary. (After Berg.)

The very beautiful and praiseworthy investigations of M. Tulasne have shown that ergot is not the diseased grain of the rye, but is the *sclerotium* of a fungus, the *Claviceps purpurea*, Tulasne. This fungus has three stages in its life-history. The development of the *sphacelia*, or first stage, commences with that of the pistil, which serves as a soil for it. The ovary of the rye consists of a cellular membrane of two coats, the outer of which has a thick parenchyma, white and gorged with juice; the inner is very delicate and green. The sphacelia, when it takes possession of the ovary, identifies itself with the outer parenchyma, and in some measure replaces it, being as it were borne by the inner membrane. It rapidly increases, taking the form of the ovary, and almost obliterating its cavity. The ovule is either entirely wanting, or may be seen, on a careful examination, in an imperfect form. For some time the parasite is represented entirely by the sphacelia, which is an oblong, fungous mass, almost homogeneous, soft and tender, marked on its surface by numerous sinuous furrows, and having within many irregular cavities, which, as well as the outer coat, are uniformly covered with linear parallel cells. From the summits of these peripheric cells, internal as well as external, issue oval capsules, from ·005 to ·007 Mm. in length, which spread upon neighboring objects, and especially the glumes of the flowers they inhabit. They are a kind of reproductive cells, called conidia, which are produced by many fungi long before the perfect plant is developed. M. Tulasne calls them "*spermatia*." In the early stage the sphacelia does not affect the top of the ovary, and the stigmas attached. The stamens often abort; but the filaments and anthers may sometimes be

* For the various views that have been held in regard to the nature of ergot, see 15th edition U. S. D.: the sketch is omitted here, as being solely of historic interest.

† There is, indeed, reason for believing that this ergot is specifically identical with the official one, since Tulasne has cultivated the dissimilar sclerotia obtained from twelve species of grasses, and found the fructification in each case identical with that of the ergot of rye. Moreover, from time to time of late years epidemics of abortion in cows have been reported as produced by the use of various ergots. This is a strong indication that all the ergots are similar in medical properties. The ergot of oats is said to be of a black color, measuring from ten to twelve millimeters in length and three to four in thickness, and to have been used in Algeria as a substitute for rye ergot. (*Lond. Med. Rec.*, March, 1888.) The ergot of *diss*, an Algerian reed, *Ampelodesmos tenax*, has appeared in commerce to some extent. It is, when small, slightly curved, but when long (6–9 centimeters) it takes a spiral turn from right to left, the longitudinal furrows being present on the inner face. It is thinner, dryer, and more brittle than the ergot of rye, and has been used for the preparation of an ergotine or extract closely resembling the official one, but said to be of a clearer red or brown color. M. Lallemand asserts that the ergot of diss is twice as strong as the ergot of rye, and states that it is abundant and readily collected. It is also stated to be less hygroscopic and less apt to be attacked by acari than is the official article. (*P. J. Tr.*, xvi. 684, 1886.)

seen buried in the tissue of the sphacelia, and altered by its action. Sometimes the ovule is not completely aborted, but it is certainly never developed into a monster grain. In all ergotized plants, the pistils and stigmas, when they remain, are often covered with a mouldiness, consisting of spores and entangled filaments, which end by covering the parts with an abundant ashy or sooty powder. This is a different fungus, and was confounded by Mr. Quekett with the ergot plant. It is found as well in the non-ergotized as in the ergotized flowers, and in those of plants which do not bear ergot. At a somewhat advanced period of the development of the sphacelia, there exudes, especially from the summit, a very adhesive juice, which spreads over that structure, bearing along with it an immense number of the seedlets or "*spermaties.*" This leaves on the surface when dry an oily appearance, and afterwards the spots, where it remains, become brownish or blackish. But this exudation does not appear until the sphacelia has ceased to constitute the whole plant.

At the base of the sphacelia is produced a compact body, violet-black without and white within, which is the ergot in a rudimentary state. With this commences the second stage in the development of the fungus. The young ergot is everywhere invested by the tissue of the sphacelia (which Tulasne calls also *spermagonia*, from its office); but, as it increases, it seems to be placed below the spermatopherous apparatus, and raises it steadily out of the floral bracts which concealed it, ending by supporting it wholly at its summit. Sometimes it carries with it the atrophied ovary, which still shows the hairs that crowned it, and some remains of the stigmas. It results that the ergot, which is technically the *sclerotium* of the fungus, remains for some time concealed in the sphacelia, so that this seems to constitute the whole plant. But, when the function belonging to this has been fulfilled, it begins to become dry, and is much deformed. The ergot, on the contrary, increases in all directions, and soon appears above the glume. As it augments, the thin coating which it has received from the spermatopherous tissue, especially below, gradually becomes thinner, and seems to disappear, so that its surface, instead of being uniformly violet-black, is only here and there covered with the remains of the tissue, or with a deposit of the conidia or "*spermatie.*" Nevertheless, the sphacelia, deformed, shrunken, and worn away by rains and other causes, remains long at the top of the ergot, along with the abortive ovary, etc., and may even continue to adhere when the ergot is detached from the plant. The time required for the full development of the sphacelia and the ergot or sclerotium varies. In an example under the observation of M. Tulasne, at least a month elapsed after the appearance of the sphacelia before the growth was completed.

Ergot has absolutely nothing in common with normal grain. The anatomical structure and all the physical characters of ergot are those of the mushrooms, or rather of a sclerotic mycelium. The parenchyma, which is whitish, dry, and brittle, consists in all its parts of irregular, globular, or polyhedric thick-walled cells, intimately united, and filled with a limpid oil, but feebly colored by iodine. The superficial utricles, which alone are colored, have an outer wall thicker than the inner, and the color of these is what gives its characteristic hue to ergot. Not the least trace of starch is to be detected. If ergot be planted in a suitable soil, evidences of germination are seen in about three months. Little globular prominences appear on its surface, which gradually enlarge, and raise themselves upon cylindrical stems, and finally become perfect pilei or fruiting fungi, producing elongated, rod-like spores in flask-shaped cavities which open by a little pore. These little fungi belong to the genus *Sphæria*. As they increase, the interior of the ergot becomes exhausted, by contributing to their growth. Falling to the ground, in its natural course, the ergot in the soil germinates, and produces pilei, the spores of which, carried up with the juices of rye, become lodged in the ovary, where they begin the course of life and progress which has been delineated. Different grains are probably infested with different species of Claviceps; but there is no reason to think that any other species is concerned in the product of any official variety of ergot. (*Annales des Sciences Naturelles*, 3e sér., xx. 5, 1853.) The ergot usually projects out of the glume or husk beyond the ordinary outline of the spike or ear. In some spikes the place of the seeds is wholly occupied by the ergot, in others only two or three spurs are observed. It is said to be much more energetic when collected before than after harvest. Rye has generally been thought to be most subject to the disease in poor and wet soils, and in rainy seasons; and intense heat succeeding continued rains has been said to favor its development, especially if these circumstances occur at the time the flower is forming. It is now, however, asserted that moisture has little or nothing to do with its production. It should not be collected until some days after it has begun to form; as, according to M. Bonjean, if gathered on the first day it does not possess the poisonous properties which it exhibits when taken on the sixth day. (See *P. J. Tr.*, Jan. 1842.)

Ergot chiefly enters commerce from Russia, Germany, and Spain. Of the three varieties the Spanish ergot is considered the best, yielding usually from 13 to 15, sometimes as high as 18, per cent. of extractive. It is somewhat darker-colored, rather shorter, and more uniform than is the German ergot. An ergot of excellent quality has been sent from the Canary Islands to England.

Properties. Ergot is in solid, brittle yet somewhat flexible grains, from a third of an inch to an inch and a half long, from half a line to three lines in thickness, cylindrical or obscurely triangular, tapering towards each end, obtuse at the extremities, usually curved like the spur of a cock, marked with one or two longitudinal furrows, often irregularly cracked or fissured, of a violet-brown color and often somewhat glaucous externally, yellowish white or violet-white within, of an unpleasant smell when in mass resembling that of putrid fish, and of a taste which is at first scarcely perceptible, but ultimately disagreeable and slightly acrid. "Somewhat fusiform, obtusely triangular, usually curved, about 2 or 3 Cm. long, and 3 Mm. thick; three-furrowed, obtuse at both ends, purplish-black, internally whitish with some purplish striæ, breaking with a short fracture; odor peculiar, heavy, increased by trituration with potassium or sodium hydrate test-solution; taste oily and disagreeable. Old Ergot, which breaks with a sharp snap, is almost or entirely devoid of a pinkish tinge upon the fracture, is hard and brittle between the teeth, and is comparatively odorless and tasteless, should be rejected." *U. S.* Ergot yields its virtues to water and alcohol. The aqueous infusion or decoction is claret-colored, and has an acid reaction. It is precipitated by lead acetate and subacetate, silver nitrate, and tincture of galls, but affords with iodine no evidence of the presence of starch. Long boiling impairs the virtues of the medicine.

Ergot has been analyzed by Vauquelin, Winckler, Wiggers, Wright, Legrip, Wenzell, Tanret, Dragendorff, and several others. Dr. Wright supposed the virtues of ergot to reside in the fixed oil, which he therefore recommended as a substitute for the medicine. The *oil of ergot*, when obtained from grains recently collected, is, according to Dr. Wright, often quite free from color; but as usually prepared it is reddish brown. It has a disagreeable, somewhat acrid taste, is lighter than water, and is soluble in alcohol and alkaline solutions. It is prepared by forming an ethereal tincture of ergot by the process of displacement, and evaporating the ether with a gentle heat. It may be more cheaply prepared by substituting benzin for ether. Experience has shown that, though the oil thus prepared with ether may have produced effects analogous to those of ergot, they were to be ascribed rather to some principle extracted along with the oil by the menstruum than to the oil itself; for, when procured by expression, this has been found to be inactive, although Prof. Procter has ascertained that it contains a little *secalin*, one at least of the active principles of ergot, which may be separated from it by washing with acidulated water. According to Mr. T. R. Baker, the oil has a taste and smell similar to those of castor oil, with which it also agrees in ultimate composition, and yields analogous results in saponification. (*A. J. P.*, xxiv. 101–2.) Dr. T. C. Herrmann investigated specially the chemical constitution of the oil of ergot. As obtained by means of ether, it was brownish yellow, of an aromatic smell and acrid taste, viscid, of the sp. gr. 0·9249, and without the drying property. It consists of 22·703 per cent. of palmitic acid, 69·205 of oleic acid, and 8·091 of glycerin. (*N. R.*, 1872, p. 238; from *Buchner's Repertorium*, 1871, p. 283.) The *sugar of ergot* was found by Mitscherlich to be peculiar, and was named by him *mycose*. He described it as crystallizable, very soluble in water, almost insoluble in cold but dissolved by about 100 parts of boiling alcohol, quite insoluble in ether, and without the action of glucose on the salts of copper. Its formula is $C_{12}H_{22}O_{11} + 2H_2O$, allying it to cane sugar, and possibly making it identical with *trehalose*. According to Wenzell (*A. J. P.*, May, 1864), ergot of rye contains two peculiar alkaloids, which he designated *ecboline* and *ergotine*, and claimed to be the active principles of the drug. The two bases of ergot are, according to Wenzell, combined with *ergotic acid*, the existence of which has been further admitted by Ganser. It is said to be a volatile body yielding crystallizable salts.

A crystallized, colorless alkaloid, *ergotinine*, $C_{35}H_{40}N_4O_6$, which is probably identical with Wenzell's ergotine, was isolated (1877–78) by Tanret. He obtained it to the amount of 0·04 per cent., some amorphous ergotinine, moreover, being present. The solutions of ergotinine turn greenish and red very soon; they are fluorescent. Sulphuric acid imparts to it a red, violet, and finally blue hue. The "*ecboline*" of Wenzell was named by Kobert *cornutine*. C. C. Keller asserts that *picrosclerotine*, *cornutine*, and Tanret's *ergotinine* are identical, and that ergot contains but one alkaloid which persists in it for one year unaltered. This alkaloid is crystalline, insoluble in water, soluble in alcohol and chloroform, slightly soluble in ether; by sul-

phuric acid it is colored violet-blue. (*Chem. Zeit.*, 1894, 105.)* C. Jakoby (*Pharm. Centralh.*, 1897, 58) believes that he has isolated from ergot three chemically different bodies, *chrysotoxin*, *secalintoxin*, and *sphacelotoxin*. All of these are, however, therapeutically similar. It is affirmed that chrysotoxin fully represents ergot pharmacologically, and retains its activity unaltered for years, whereas sphacelotoxin and secalintoxin do not.

Dragendorff and several of his pupils believe that they have isolated the following *amorphous* principles of the drug: 1, *sclerotic acid*, said to be a very active substance, used chiefly in subcutaneous injections; about 4 per cent. of colorless acid may be obtained from good ergot of rye; 2, *scleromucin*, a mucilaginous matter which may be precipitated by alcohol from aqueous extracts of the drug; 3, *sclererythrin*, the red coloring matter probably allied to anthrachinon and the coloring substances of madder, chiefly to purpurin; 4, *scleroiodin*, a bluish-black powder soluble in alkalies; 5, *fusco-sclerotinic acid;* 6, *picrosclerotine*, apparently a highly poisonous alkaloid; lastly, 7, *scleroxanthin*, $C_7H_7O_3 + H_2O$, and 8, *sclerocrystallin*, $C_7H_7O_3$, have been obtained in crystals; their alcoholic solution is but little colored, yet assumes a violet hue on addition of ferric chloride.

Tanret also observed in ergot of rye a volatile *camphoraceous* substance.

When ergot or its alcoholic extract is treated with an alkali, it yields as products of the decomposition of the albuminoid matters ammonia or ammonia bases, according to Ludwig and Stahl, *methylamine;* according to others, *trimethylamine*. Wenzell states that phosphate of trimethylamine is present in an aqueous extract of ergot, but Ganser ascertained that no such base pre-exists in ergot. Flückiger found that the crystals which abound in the extract after it has been kept for some time are an acid sodium and ammonium phosphate, with a small proportion of sulphate.

We quote from Dilg's summary of the "active constituents of ergot" (*A. J. P.*, 1878, p. 335) Dragendorff's process for the two most active constituents of ergot, *sclerotic* or *sclerotinic acid* and *scleromucin*. "Digest ergot, previously exhausted by ether and absolute alcohol, with water, dialyse, evaporate the dialysate to a syrupy consistence, and treat with sufficient alcohol to obtain a mixture containing 40 to 45 per cent. alcohol, which precipitates the potassium phosphate, while more alcohol added until the strength is increased to 75 or 80 per cent. precipitates the salts of sclerotic acid, which are soluble in dilute but insoluble in stronger alcohol, and leave about 19 per cent. of ash. The filtrate, upon which alcohol has no further effect, produces with ether a slight precipitate, which after a few days' standing forms a syrupy, brown mass, which has scarcely any medicinal virtue. The filtrate from this precipitate, in which the reactions still distinctly indicate the presence of Wenzell's alkaloids, after evaporating the ether and alcohol, does *not* produce the specific action of ergot. The dark liquid remaining on the dialysator, when mixed with sufficient alcohol to bring it to 45–50 per cent., precipitates the *scleromucin*, which while moist forms a mucilaginous solution with water, but after drying is only partially soluble, differing in this respect from sclerotic acid, which is soluble in all proportions, before and after drying.

"*Sclerotic acid* is obtained in an early pure state by kneading the mixed sclerotates, as obtained above, with 80 per cent. alcohol, and afterwards dissolving them in 40 per cent. alcohol; the solution is mixed with an excess of hydrochloric acid, and after several hours precipitated with absolute alcohol, whereby the ash is reduced to about 3 per cent., and consists mainly of some silica, magnesia, and phosphates of iron and potassium. The acid is not a glucoside, and yields no precipitates with the reagents for alkaloids, except with phosphomolybdic acid a yellow, and with tannin a nearly colorless one. Sclerotic acid is obtained as a yellowish brown, tasteless, and inodorous substance, which has a very slight acid reaction, and is hygroscopic without being deliquescent. It is very well adapted for subcutaneous applications, in doses of 0·03–0·045 Gm. *Scleromucin* is darker in color, slightly hygroscopic, gummy, inodorous, and tasteless, yields 26·8 per cent. of ash, and, like sclerotic acid, contains nitrogen, is not a glucoside, and is precipitated by tannin and phosphomolybdic acid. Good ergot yields about 4 to 4½ per cent. of sclerotic acid, and about 2 to 3 per cent. of scleromucin."

For an improved process for making sclerotic acid, by Podwissotzky, see *N. R.*, 1883, p. 271. Voswinkel obtained from ergot a brown amorphous substance, which he proved by hydrolysis to yield *mannose*. The body is a hemi-cellulose, and the name *mannan* has been given to it. He states that Dragendorff's sclerotic acid and scleromucin are identical with mannan. (*Pharm. Centralhalle*, 1891, p. 531.)

* Keller gives a very full account of this single alkaloid, its color reactions, yield from commercial samples, and method for the analysis of ergot and assay of its value. (*Proc. A. P. A.*, 1895, 542.)

Kobert (*Pharm. Centralhalle*, 1884, p. 607; All, *Das Mutterkorns*, Leipzig, 1884) found three physiologically active principles: 1st, *ergotic acid*, which he considers the principal constituent of the sclerotic acid of Dragendorff and Podwissotzky, and which is isolated by precipitation with ammoniacal lead subacetate, 2d, *sphacelic acid*, which can be isolated by taking advantage of the insolubility of the free acid in water and its solubility in alcohol; 3d, the alkaloid *cornutine*, which is not identical with the crystalline or with the amorphous ergotinine of Tanret; it is readily soluble in alcohol, and is obtained from an alkaline aqueous solution by agitation with ether. This alkaloid is said to be very poisonous. Dr. Kobert's conclusions have been questioned by Tanret (*P. J. Tr.*, 1885, p. 889), but the former reaffirms his statements and believes that ergotinine is worthless, and that the activity of fresh ergot is due to sphacelic acid and cornutine as above described: the important fact, however, is noted that these latter principles entirely lose their properties on keeping; he therefore proposes that they be made into pills and coated to protect them. (*Archiv d. Pharm.*, 1886, p. 597.) Kobert's process for cornutine we append in a foot-note.* For assay of ergot by Dr. Dohme, see *Proc. A. P. A.*, 1895, 263.

The odor of ergot is no doubt owing to the liberation of its volatile alkaloid, probably in consequence of a slow decomposition of the native salt. A method of detecting ergot in a mixed powder, rye flour for example, is thus afforded. If, on the addition of solution of potassa, the odor of ergot be perceived, its presence is sufficiently proved.

Ergot, when perfectly dry and kept in well-stopped bottles, will retain its virtues for a considerable time, but exposed to air and moisture it speedily undergoes chemical change and deteriorates. M. Gobley kept for more than ten years, perfectly sound, some ergot which he had selected from the year's harvest, carefully sifted, wiped with linen, then exposed to a heat of from 50° to 60° C. for three or four hours, and finally put into small boxes, holding each about 30 Gm. (a troyounce), previously heated with the ergot, and finally closed air-tight with pitch. (*Journ. de Pharm.*, Mar. 1873, p. 216.) It is, moreover, apt to be attacked by a minute worm, which consumes the interior of the grain, leaving merely the exterior shell and an excrementitious powder. This insect is sometimes found in the ergot before removal from the plant. In the state of powder the medicine still more readily deteriorates; but Prof. Dragendorff believes that the decay is due to oxidization of the fatty principles of the ergot, and can be prevented by depriving the ergot of its oil before powdering. (*A. P. S.*, xxv.) This has since been confirmed by Zschiesing, who preserved ergot for two years, and Bombelon, who kept ergot in good condition for nine years, by previously removing the fixed oil with ether. (*Phar. Zeitung*, No. 49, p. 51; *A. J. P.*, 1881, p. 457.) It is best, as a rule, to renew it every year or two. M. Viel recommends that it should be well dried at a gentle heat, and incorporated with double its weight of loaf sugar, by means of which, if protected from moisture, it will retain its virtues for many years. According to M. Zanon, the same result is obtained by stratifying it with well-washed and perfectly dried sand, in a bottle from which air and light are excluded. Camphor and powdered benzoin are said to prevent injury from worms. Aymoiner immerses fresh ergot in an ethereal solution of Tolu, dries it, and preserves in tightly closed bottles.

Medical Properties and Uses. Given in small doses to men or non-pregnant women, ergot produces no obvious effect. In the quantity of half a drachm or a drachm it may occasion nausea or vomiting, but in order to produce very distinct symptoms enormous doses must be taken. We have given the fluid extract in doses of three ounces, daily, for one or more weeks without perceiving any marked effect. In some cases, after very large doses the pulse is distinctly reduced in frequency, and Dr. Hardy has noted that the fœtal cardiac pulsations are rendered infrequent by it. But one instance of fatal poisoning has occurred, except when abortion has been produced. A case is recorded in which ergot produced great prostration, with an almost absent pulse, paleness and coldness of the surface, partial palsy, with pricking of the limbs, and great restlessness, without stupor or delirium. (*Gazette Méd. de Paris*, Juillet 25, 1857.) The symptoms in another case, recorded by Dr. Oldright, were very similar to those just detailed. The most characteristic is the intense coldness of the surface, which has also

* Exhaust the drug with water, acidulated with hydrochloric acid, neutralize the aqueous solution nearly with sodium carbonate, evaporate in vacuo at a very low temperature to a syrupy consistence, and treat with alcohol. Filter, distil off the alcohol carefully, and treat the nearly dry product with anhydrous ether, which removes any ergotinine present. After making the residue alkaline with sodium carbonate it is treated with acetic ether, and the solution shaken with water containing a little citric acid, which removes the cornutine in an almost pure state. This process is repeated, and it is finally precipitated from its acetic ether solution by anhydrous ether. Prepared in this way, cornutine will, if kept dry, and not exposed to light, remain unchanged. (The author kept some for three years.) (*Year-Book of Pharmacy*, 1891, p. 190.)

been noted in the lower animals. In the fatal case narrated by Dr. Pratschke, uneasiness in the head, oppression of stomach, diarrhœa, urgent thirst, burning pains in the feet, tetanic spasms, violent convulsions, and death ensued upon eating freely of ergotized grain. (*Lon. Med. Gaz.*, Oct. 1850, p. 579.) The long-continued and free use of ergot is highly dangerous, even when no immediate effects are perceptible. Fatal epidemics in different parts of the continent of Europe, particularly in certain provinces of France, have long been ascribed to the use of bread made from rye contaminated with this fungus.* Dry gangrene, typhus fever, and disorder of the nervous system attended with convulsions, are the forms of disease which have followed the use of this unwholesome food. It is true that ergot has been denied to be the cause; but accurate investigations made by competent men upon the spot where the epidemics have prevailed, together with experiments upon inferior animals,† leave no room for reasonable doubt that at least the gangrenous affection alluded to has resulted from it.

Upon the lower animals ergot acts as upon man. Besides its influence upon the uterus, the most important physiological action of the drug is upon the vaso-motor nervous system. It has been abundantly proved that in full therapeutic dose it raises remarkably the arterial pressure by producing a general vaso-motor spasm. This spasm is almost certainly the result of a stimulation of the vaso-motor nerve-centres, but there are still some authorities who believe that the drug acts peripherally upon the muscular coats of the vessels or upon the nerves connected therewith.

On the continent of Europe, in Germany, France, and Italy, ergot has long been empirically employed by midwives for promoting the contraction of the uterus; and its German name of *mutterkorn* implies a popular acquaintance with its peculiar powers. But the attention of the medical profession was first called to it by Dr. Stearns, of Saratoga County, N.Y. (*New York Medical Repository*, 1807.) In its operation upon the pregnant uterus, it produces a constant unremitting contraction and rigidity, rather than that alternation of spasmodic effort and relaxation which is observable in the natural process of labor. Hence, unless the os uteri and external parts are sufficiently relaxed, the medicine is apt to produce injury to the fœtus by the incessant pressure which it maintains; and the death of the child is thought not unfrequently to have resulted from its injudicious employment. The cases to which it is thought to be especially adapted are those of lingering labor, when the os uteri is sufficiently dilated and the external parts sufficiently relaxed, when no mechanical impediment is offered to the passage of the child, and the delay is ascribable solely to want of energy in the uterus. Other cases are those in which the death of the fœtus has been ascertained, and when great exhaustion or dangerous constitutional irritation imperiously calls for speedy delivery. The medicine may also be given to promote the expulsion of the placenta, to restrain inordinate hemorrhage after delivery, and to hasten the discharge of the fœtus in protracted cases of abortion. In women subject to dangerous flooding, a dose of ergot given immediately before delivery is said to have the happiest effects. Ergot is also much used to cause the expulsion of coagula of blood, polypi, and hydatids from the uterine cavity, and even a number of successful cases of its employment for the destruction by strangulation of fibroid tumors of the uterus have been reported. In uterine hemorrhage, unconnected with pregnancy, the medicine is very useful; and it is probably the most used and most efficient of all remedies in pulmonary and other similar internal hemorrhages. Its action in these cases is no doubt the result of the contracting power it has over the smaller vessels. This action of ergot upon the blood-vessels suggests its employment in those cases in which there is local or general dilatation of the blood-vessels. It has been used in pulmonic congestion with apparent good results, and it has been highly lauded in the first stages of pneumonia by several clinicians, especially by Dr. J. E. Kelly (*Med. Register*, 1887, vol. x.), as giving immediate relief when injected hypodermically in low forms of pulmonary hyperæmia such as occur in typhoid fevers. It will probably also be found of service as a vaso-motor stimulant in surgical shock, and has been much used against *cerebral congestion*, in *spinal congestion*, in *colliquative sweats*, and in *diabetes insipidus*. In *apoplexy*, owing to its pronounced tendency to increase the blood-pressure, it must be given with the greatest caution, if at all. The best preparation of ergot for internal administration, except when an immediate influence is desired, is the official solid extract given in capsules. The fluid extract is perhaps absorbed a little more quickly, but it is much more apt to sicken the stomach. The dose of solid extract is 5 to 30 grains (0·33–1·95 Gm.); of the fluid extract, half a fluidrachm

* Dr. Hofmann states that $\frac{1}{10}$ per cent. of ergot can be detected in bread by macerating 30 grains of coarsely grated bread in 40 grains of ether and 20 drops of diluted sulphuric acid for 24 hours, straining, shaking with solution of sodium bicarbonate and allowing to stand, when the solution separates and is of a violet color. (See also *N. R.*, 1883.)

† An epidemic among sheep was caused by eating ergotized grain. (See *P. J. Tr.*, x. 195.)

to two fluidrachms (1·8–7·4 C.c.). In *hemorrhoids*, and in *varicose veins* of the leg, it has been injected into the diseased tissue with success, but probably acts only by producing a severe local inflammation.

Under the name of *Bonjean's ergotine*, a purified extract is sometimes used in the dose of from five to ten grains (0·33–0·65 Gm.). It is made by exhausting ergot with water, evaporating to the consistence of syrup, precipitating the albumen, gum, etc., by a large excess of alcohol, decanting the clear liquid, and evaporating to the consistence of a soft extract. When promptness and certainty of action are required, ergot may be used hypodermically. Solutions of extract of ergot are very prone to undergo speedy decomposition, and, as such altered solutions are very irritating, it is important that solutions for hypodermic use be made freshly, especially as the experiments of M. Engelmann (*Deutsch. Med. Wochen.*, Sept. 30, 1886) have shown that the addition of ordinary antiseptic agents to such solutions, unless in very large amount, simply delays decomposition, and that the changes may be far advanced although the preparations seem to the eye unaltered. Notwithstanding all possible precautions, the hypodermic injections of ergot have a tendency to produce local inflammations and abscesses, but the danger may be reduced to a minimum by absolute obedience to the following directions: Extract of ergot, five grains, should be dissolved in twenty minims of recently boiled water, and two or three drops of glycerin and half a drop of carbolic acid be added. This solution should be filtered to remove any solid particles, and then at once be thrown deeply into the cellular tissues.

Dujardin-Beaumetz gives the dose of Tanret's crystallized ergotine for hypodermic use as 5 milligrammes ($\frac{7}{100}$ grain). (*Bull. Thérap.*, xciv. 236.) Sclerotic acid does not represent ergot, as was, so far as concerns the commercial article, shown by experiments made in the laboratory of the University of Pennsylvania; indeed, the research of Nikitin, who claims that it is the active principle, affords abundant evidence that it is not so. (*Lond. Med. Record,* 1879, p. 21.)

ERIODICTYON. U. S. Eriodictyon.

(ĔR-Ĭ-Ō-DĬC'TĬ-ŎN.)

"The leaves of Eriodictyon glutinosum, Bentham (nat. ord. Hydrophyllaceæ)." *U. S.*

Yerba Santa; Mountain Balm, Consumptive's Weed, Bear's Weed.

Gen. Ch. Low shrubs (California to New Mexico), with alternate pinnately veined and finely reticulated leaves of firm or coriaceous texture, their margins mostly beset with rigid teeth, at base tapering into more or less of a petiole; the flowers scorpioid-cymose, forming a terminal usually naked thyrsus. Sepals narrow, not enlarging upwards. Corolla violet or purple, or sometimes white. Filaments adnate variably and sometimes very extensively to the tube of the corolla, usually sparsely hirsute. Ovary nearly or completely two-celled by the meeting of the dilated placentæ in the axis. Capsule small (a line or two long), globose-ovate, pointed.

E. glutinosum grows upon dry hills abundantly in California. It is glabrous, resinous to the feeling, with lanceolate leaves from three to six inches long, irregularly more or less serrate, sometimes entire, whitened beneath, between the reticulations, by a minute and close tomentum, above glabrous. The corolla is half an inch long, tubular funnel-form; the calyx is about one-sixth of an inch long, and slightly, sparsely hirsute. The leaf structure has been studied by F. W. Ritter. (See *A. J. P.*, 1895, 565.)

E. tomentosum, which grows often along with *E. glutinosum*, especially in the southern part of California, is readily distinguished by its dense coat of short villous hairs, whitish or rusty-colored with age. It is also a larger shrub than *glutinosum*, has its corolla somewhat salver-form, and its leaves oblong or oval, and obtuse.

Properties. The Eriodictyon leaves have already been sufficiently described, but they are further characterized by the U. S. Pharmacopœia as "oblong-lanceolate, 5 to 10 Cm. long, acute at the apex, and below narrowed into a short petiole, the margin sinuately toothed to nearly entire; upper surface green, smooth, and covered with a brownish resin; lower surface reticulate and minutely white-tomentose; odor somewhat aromatic; taste balsamic and sweetish." *U. S.* H. S. Wellcome (*Pharmacist*, 1876, p. 73) found the drug to contain two aromatic resins, whilst an aqueous infusion of leaves which had been exhausted by alcohol yielded an intensely bitter extract. According to the analysis of Chas. Mohr (*A. J. P.*, 1879, 549), it contains tannic acid and 8 per cent. of an acrid, bitter resin, upon which its activity is believed to depend, also a minute quantity of volatile oil. R. Rother describes (*A. J. P.*, 1887, p. 225) an acid resin which forms with bases quite soluble salts. The acid resin was obtained after spontaneous volatilization of the several solvents as a green-yellow transparent mass. Thal (*Pharm. Zeit. Russl.*, 1883, p. 209) showed the presence of *ericolin*, $C_{34}H_{56}O_{21}$.

Medical Properties. The yerba santa has long been used in California as a bitter tonic, and also as a stimulant balsamic expectorant. There is considerable testimony to its usefulness in *asthma*, *chronic bronchitis*, and allied conditions; also in chronic inflammation of the genito-urinary tract. Attention has been called by Dr. Kier to its remarkable power of disguising the taste of quinine. It is best exhibited in the form of the official fluid extract, the dose of which is one-half to one drachm (1·8 to 3·69 C.c.); a solid extract has been made, which may be given in doses of from five to fifteen grains (0·324 to 0·972 Gm.). In cases of asthma eriodictyon is often used by smoking. The aromatic syrup is well adapted as a vehicle for quinine. (See *Syrupus Eriodictyi Aromaticus*, National Formulary.)

EUCALYPTI GUMMI. Br. Eucalyptus Gum.

(EŪ-CA-LĬP'TĪ GŬM'MI—yū-kă-lĭp'tī.)

"A ruby-colored exudation, or so-called red gum, from the bark of Eucalyptus rostrata, Schlechtendal, and some other species. Imported from Australia." *Br.*

A kino-like exudation is obtained in Australia from various species of Eucalyptus, but the commercial is chiefly yielded by *E. rostrata*, which occurs over a wide area along watercourses in Australia and New South Wales. It is a large, gregarious tree, with almost linear-pointed leaves and shining bark, and is especially characterized by the long beak upon the operculum of its seed-vessel. The gum is obtained by cutting the tree, inserting a piece of bent tin, and catching the red, thick liquid in a vessel. The average yield is said to be about one quart per tree. In a few days the liquid hardens into a kino-like mass.

Red gum occurs in commerce in grains or small masses of a purplish-red, ruby-red, or garnet color, closely resembling ordinary kino, but somewhat more brilliant, with a distinctly bitterish taste, tough, and adhering to the teeth. It does not equal kino in astringency. From 80 to 90 per cent. of it is soluble in cold water, forming a neutral solution. It is almost entirely soluble in alcohol (90 per cent.). For further description, see "Australian Kino," under *Kino*. In the analyses made by J. H. Maiden red gum yielded about 4·5 per cent. of tannic acid. (*A. J. P.*, 1897.) It is used for *diarrhœas* of relaxation, and other affections for which kino has been employed, and is also largely employed as the basis of lozenges and gargles.* Dose, from two to ten grains (0·13 to 0·65 Gm.).

EUCALYPTOL. U. S. Eucalyptol.

$C_{10}H_{18}O$; 153·66. (EŪ-CA-LĬP'TŎL—yū-kă-lĭp'tŏl.)

"A neutral body obtained from the volatile oil of Eucalyptus globulus, Labillardière, and of some other species of Eucalyptus (nat. ord. Myrtaceæ). Eucalyptol should be kept in well-stoppered bottles, in a cool place, protected from light." *U. S.*

This is a new official liquid of the U. S. P. 1890. In the distillation of eucalyptus leaves, the portion which comes over between 170° C. (338° F.) and 178° C. (352·4° F.) is set aside as crude eucalyptol To obtain it pure a redistillation from caustic potash or calcium chloride is necessary. It is very liquid, nearly colorless, with a strong, aromatic, camphoraceous odor, is slightly soluble in water, but very soluble in alcohol. Nitric acid produces with it a crystallizable acid; by the action of phosphoric anhydride (*Journ. de Pharm.*, 4e sér., xii. 204) it is converted into *eucalyptene*, $C_{10}H_{16}$, a substance allied to cymene, and *eucalyptolen*.

The presence of *cymene*, $C_{10}H_{14}$, was asserted by Faust and Homeyer (1874), but its presence in the oil of *Eucalyptus globulus* is denied by H. Schulz (1881), who made a careful study of this variety, although eucalyptol may be converted into cymene by the action of P_2S_5.

C. Jahns (*A. J. P.*, 1885, p. 237) gave the formula $C_{10}H_{18}O$ to eucalyptol, and showed it to be identical with cajuputol, or, as it is now generally known, *cineol*. Wallach (*Ann. der Ch. und Phar.*, 248, pp. 278–283) showed that the oil from *E. globulus* contained cineol (eucalyptol) and *dextro-pinene*, while that from *E. amygdalina* contained cineol and *lævo-phellandrene*.

The U. S. Pharmacopœia describes it as follows: "A colorless liquid, having a characteristic, aromatic, and distinctly camphoraceous odor, and a pungent, spicy, and cooling taste. Specific gravity: 0·930 at 15° C. (59° F.). Boiling point: 176° to 177° C. (348·8° to 350·6° F.).

* *Eucalyptus Tooth-Wash.* The following formula was devised by Jos. W. England. As alum is destructive to the teeth, it is preferable to omit it. Potassium chlorate, 120 grains; boiling water, 4 fluidounces; powdered alum, 60 grains; stronger rose water, 2 fluidounces, 5 fluidrachms; glycerin, 4 fluidrachms; syrup, 4 fluidrachms; fluid extract of eucalyptus rostrata (red gum), 3 fluidrachms. Dissolve the potassium chlorate in the boiling water, cool, and reserve. Dissolve the alum in the stronger rose water, add the glycerin, syrup, and fluid extract of red gum in the order named, and then add this to the reserved portion. The product is a transparent ruby-red liquid, of a very agreeable odor and taste, which may be used pure or diluted with equal bulk of water.

It is optically inactive (distinction from the *oil of Eucalyptus* and *many other volatile oils*). When exposed to a temperature some degrees below 0° C. (32° F.), or placed in a freezing mixture, it solidifies to a mass of colorless, needle-shaped crystals, which liquefy at —1° C. (30·2° F.). Soluble, in all proportions, in alcohol, carbon disulphide, and glacial acetic acid. If a portion of Eucalyptol be shaken with an equal volume of sodium hydrate test-solution, it should not diminish in volume. Its alcoholic solution should be neutral to litmus-paper, and should not assume a brownish or violet color on the addition of a drop of ferric chloride test-solution (absence of *phenols*)."

Medical Properties. Eucalyptol has been used with very good results, instead of oil of eucalyptus, as a stimulant expectorant in *catarrhal pneumonia*, chronic *bronchitis*, *bronchorrhœa*, and other catarrhal conditions of the respiratory mucous membranes. It has also been employed in chronic *inflammation* of the *genito-urinary* mucous membranes, and locally as an antiseptic dressing to *ulcers*, and as a counter-irritant in *neuralgia* and *rheumatism*. It may be given in doses of from 5 to 10 minims (0·3 to 0·6 C.c.) four to six times a day, best administered in capsules; and its solution in fatty oil has been used hypodermically.

EUCALYPTUS. U. S. Eucalyptus.

(EŪ-CĄ-LĬP'TŲS—yū-ką-lĭp'tųs.)

"The leaves of Eucalyptus globulus, Labillardière (nat. ord. Myrtaceæ), collected from the older parts of the tree." *U. S.*

Eucalyptus Leaves; Feuilles d'Eucalyptus, *Fr.*; Eucalyptus-Blätter, *G.*

Gen. Ch. Calyx obovate or globose cupulæform, the tube persistent, the limb deciduous, dehiscing by a circular irregular line from the operculiform base. *Stamens* free. *Capsule* 4-loculate or by abortion 3-loculate, dehiscent at the apex, many-seeded. *De Candolle, Prodromus*, iii. 220.

The genus Eucalyptus affords one of the most characteristic features of the Australian and Tasmanian landscapes. There are about one hundred and thirty-five described species, all evergreens, and most of them large trees, popularly known as *Gum trees*, *Woolly butts*, *Iron barks*, etc.* The most important of them is the *E. globulus*.

E. globulus. Labill. *B. & T.* ii. 109. The young operculum conical, the length of the four-sided cupule, the adult depressed and mucronate in the middle; axillary peduncles very short, one-flowered; leaves alternate, lanceolate, subfalcate.

This is one of the largest known trees, attaining sometimes a height of 300 or even 350 feet, with a smooth, ash-colored bark; leaves a foot in length, and varying, according to age, from a glaucous white to a bluish-green color; and large pinkish-white axillary flowers, sometimes single, sometimes in clusters. Although its wood is very resinous, hard, and durable, the tree is remarkable for the rapidity of its growth, reaching, under favorable circumstances, fifty feet of height in five or six years. It flourishes best in valleys having a rich, moist soil, and has very largely been naturalized in semi-tropical countries, partly on account of its economic value, but chiefly because of the reputation it enjoys as a means of overcoming malaria. It does not seem to require great heat for its perfection, but is exceedingly sensitive to frost. Large forests of it have been planted in Algeria and Southern Europe, and its culture is spreading to California, Florida, and other of our Southern States. Its sanitary powers appear to be established, numerous notoriously miasmatic stations and districts having been rendered healthful by its growth. It is probable that the destruction of the miasma is due not so much to emanations from the tree as to the fact that it evaporates water so rapidly from its innumerable large leaves as to drain the swamps and marshes in which it is planted. It is possible, however, that the large amount of volatile oil which must escape from it has some effect, and it is even affirmed (*A. J. P.*, 1875, p. 423) that the parasitic phylloxera will not attack grape-vines growing near it.

The eucalyptus trees afford a number of products besides the official oil. The eucalyptus oil of commerce is, indeed, composed chiefly of the oils of *E. amygdalina* and *E. dumosa*, which yield a very much larger product than does the official species. The oils of *E. piperita* and *E. hæmastoma* have a peppermint odor, and that of *E. citriodora* a citron-like odor, whilst the oil of *E. staigeriana* exactly resembles the oil of verbena: it is probable that these oils will come into commerce for the purposes of the perfumer.

* Descriptions and accurate figures of most of this species may be found in Baron Ferd. von Mueller's *Eucalyptographia: a Descriptive Atlas of the Eucalypts of Australia and the Adjoining Islands*, London and Melbourne, 1879–1884.

Properties. The leaves are the official portion of the plant: they are "petiolate, lanceolately scythe-shaped, from 15 to 30 Cm. long, rounded below, tapering above, entire, leathery, grayish-green, glandular, feather-veined between the midrib and marginal veins; odor strongly camphoraceous; taste pungently aromatic and somewhat cooling, bitter and astringent." *U. S.*

In March, 1870, M. Cloez (*Journ. de Pharm.*, 4e sér., xii. 201) reported an elaborate chemical study of the eucalyptus leaves, and his results have been substantially confirmed by Debray (*De l'Eucalyptus Globulus*, Paris, 1872), M. Rabuteau (*Mém. de l'Académie*, Nov. 1872), and Mr. Broughton (*P. J. Tr.*, 3d ser., iii. 463). M. Cloez found, besides chlorophyll, resin, tannin, and inert substances, an essential oil, upon which the virtues of the drug appear to depend. Of this oil the fresh leaves afforded 2·75 parts per hundred, the recently dried leaves 6 parts; leaves which had been kept some time yielded a much smaller percentage. In the distillation, the oil for a time comes over freely at from 170° C. (338° F.) to 178° C. (352·4° F.); subsequently another portion of oil distils at 188° C. (370·4° F.) to 190° C. (374° F.), and finally a very minute portion does not volatilize until the temperature reaches 200° C. (392° F.). M. Cloez believes the oil to be composed of two camphors, differing in their volatility. The bulk of the oil yielded is the portion first distilled: to this Cloez has given the name of *eucalyptol*, or, as it is now also called, *cineol*, $C_{10}H_{18}O$. (See previous article.) Many of the oils yielded by species of Eucalyptus do not contain eucalyptol.* Any oil intended for medical use should have in it from 60 to 70 per cent. of pure eucalyptol crystallizing at —1° C.

According to M. Duquesnel, the oil of eucalyptus is adulterated—with alcohol, to be detected by means of fuchsin, which is insoluble in the pure oil but soluble in that containing even a very small percentage of alcohol; with fixed oil, to be detected by boiling with water, when the fixed oil remains on the surface; with essential oil of copaiba or turpentine, to be detected by means of the boiling point, that of eucalyptol being 170° C. (338° F.), that of oil of turpentine 155° C. (311° F.), that of oil of copaiba 260° C. (500° F.). (*Journ. de Pharm.*, 4e sér., xvi. 45.)

Medical Properties. Eucalyptus was originally recommended as a remedy in intermittent fever, but experience has failed to establish its value as an antiperiodic. Whatever medical virtues it possesses beyond astringency reside in the volatile oil. This when applied locally acts as a powerful irritant. When taken internally in doses of from 20 to 30 drops, it causes increased rapidity of pulse and general excitation, with restlessness and increased venereal appetite, usually followed by a feeling of calmness and repose, ending in sleep. In some cases, disturbance of the bowels, fever, constitutional disturbance, and even symptoms of cerebral congestion have been produced. In animals small doses produce the same effect as in man, and after large doses symptoms of general depression are manifested by falling of the arterial pressure, progressive diminution of temperature, muscular weakness deepening into paralysis, loss of sensibility, irregular respiration, and finally death from failure of respiration. Upon man, when taken in sufficient quantity, the oil exerts a similar influence. In a case noted by M. Gimbert, 80 drops of the oil produced in an old man a feeling of great internal heat, followed by almost complete loss of power and of feeling in the limbs; and after 75 drops Prof. Binz noted somewhat similar phenomena. The palsy produced by toxic doses is due to a direct action upon the spinal cord. Taken internally, it is eliminated by the breath, to which it imparts its odor, and also, in a condition of oxidation, by the kidneys, to the secretion of which it gives a strong smell of violets. M. Gimbert found that in rabbits it augmented to a marvellous extent the excretion of urea. As a stimulating narcotic the oil of eucalyptus has been used with asserted success in *migraine* and other forms of neuralgia. As an antispasmodic it has been highly lauded in *asthma*. In this affection it is best given by inhalation. Cigarettes may be made by rolling up the dried leaves, or the vapor from boiling water containing the oil may be inhaled. In chronic or subacute bronchitis it may often be employed with advantage, especially where there is a tendency to spasm. In subacute or chronic inflammation of the genito-urinary organs it is said to exert a very happy influence. The experiments of Binz and of Gimbert have shown that it acts very positively upon the infusoria and other low forms of life. Gimbert even claims superiority for it as an antiseptic over carbolic acid. Externally it may be used in chronic skin affections and ulcerations when a stimulant antiseptic application is indicated. Various formulas have been published for tinctures, fluid extracts, etc., but either the oil or eucalyptol should be preferred. Dose of the oil, five to ten drops (0·25 to 0·5 C.c.).

* Schimmel & Co.'s Semi-Annual Report for April, 1897, on pages 18 to 21, gives the composition of the oils from numerous species of *Eucalyptus*, showing quite a variety of components.

EUONYMUS. U. S. (Br.) Euonymus. [Wahoo.]

(EŪ-ŎN′Ȳ-MŬS—yū-ŏn′ȳ-mŭs.)

Euonymi Cortex, *Br.;* Euonymus Bark.

"The bark of the root of Euonymus atropurpureus, Jacquin (nat. ord. Celastrineæ)." *U. S.* "The dried root bark of Euonymus atropurpureus, Jacquin." *Br.*

Gen. Ch. Flowers perfect. *Sepals* 4 or 5, united at the base, forming a short and flat calyx. *Petals* 4–5, rounded, spreading. *Stamens* very short, inserted on the edge or face of a broad and flat 4–5-angled disk, which coheres with the calyx and is stretched over the ovary, adhering to it more or less. *Style* short or none. *Pod* 3–5-lobed, with 1–3 seeds in each cell in a red arillus.

Euonymus atropurpureus. Willd. *Sp. Plant.* i. 1132; Gray's *Manual,* p. 81; figured in Griffith's *Med. Bot.,* p. 219. The plant has been named variously *wahoo, spindle-tree,* and *burning-bush.* It is a tall, erect shrub, with quadrangular branchlets, and opposite, petiolate, oval-oblong, pointed, serrate leaves. The flowers, which stand in loose cymes on axillary peduncles, are small and dark purple, with sepals and petals commonly in fours. The capsule or pod is smooth and deeply lobed. The plant is indigenous, growing throughout the Northern and Western States, and sometimes cultivated for the beauty of its crimson fruit.

The plants belonging to this genus are shrubs or small trees, presenting in the autumn a striking appearance from the rich red color of their fruit, which has obtained for them the name of *burning-bush. E. americanus* and *E. europæus* have been cultivated in gardens as ornamental plants. Two or more of the species have been used in medicine. Their properties are probably similar, if not identical. Grundner, who experimented with the fruit of *E. europæus,* found it to have no other effect than that of a diuretic. (*Pharm. Centralbl.,* 1847, p. 873.) An oil expressed from the seeds is used in Europe for the destruction of vermin in the hair, and sometimes also as an application to old sores. (*Ibid.,* 1851, p. 641.) Dr. Griffith says that the seeds of this and other species are purgative and emetic, and that the leaves are poisonous to sheep and other animals feeding on them. He states also that the inner bark of *E. tingens* is beautifully yellow, and used in India for dyeing, and in diseases of the eye. (*Med. Bot.,* p. 220.) It is probable that much of the wahoo of our drug-stores has been obtained from *E. americanus,* which is distinguished from *E. atropurpureus* by its rough, warty, depressed pods, and almost sessile, thickish leaves. This bark was introduced into the last British Pharmacopœia in the supplement.

Properties. The dried bark is in thin pieces, whitish with a darker grayish epidermis, brittle, of a feeble, peculiar, not disagreeable odor, and a bitterish slightly sweetish taste, and somewhat pungent after-taste. "In quilled or curved pieces, from 2 to 5 Mm. thick; outer surface ash-gray, with blackish patches, detached in thin and small scales; inner surface whitish or slightly tawny, smooth; fracture smooth, whitish, the inner layers of a laminated appearance; nearly inodorous; taste sweetish, somewhat bitter and acrid." *U. S.* It imparts its virtues to water and alcohol. Analyzed by Mr. Wm. T. Wenzell, it was found to contain a bitter principle which he named *euonymin,* asparagin, a soft resin, a crystallizable resin, a yellow resin, a brown resin, fixed oil, wax, starch, albumen, glucose, pectin, and various salts of organic and inorganic acids. Euonymin was obtained by agitating with chloroform a tincture made with diluted alcohol, separating the chloroformic solution and allowing it to evaporate spontaneously, treating the residue with ether, dissolving what was left in alcohol, adding lead acetate to the solution, filtering, precipitating the lead with hydrogen sulphide, and evaporating. The euonymin obtained was uncrystallizable, intensely bitter, soluble in water and alcohol, and neutral in its reactions. It was abundantly precipitated from its solution by lead subacetate and phosphomolybdic acid. (*A. J. P.,* 1862, p. 387.) Mr. W. P. Clothier found the bark to yield no volatile oil on distillation. According to the same writer, if a concentrated tincture be poured into water, a dark yellow substance will be thrown down, containing resin and fixed oil, which is the *euonymin* of the eclectics,* very improperly so named, as, though it contains a portion of the active principle, it is a very complex substance. Mr. Clothier found it to purge actively without griping. (*Ibid.,* 1861, p. 491.) Frank V. Cassaday (*A. J. P.,* 1889, p. 284) found 1·30 per cent. of volatile oil and resin, 1·48 per cent. of *euonic acid* and resin, 2·16 per cent. of euonymin and resin, together with the usual plant constituents. Kubel has discovered in the fresh inner bark of *E. europæus* a saccharine, crystallizable substance, closely resembling mannite, but differing in its crystalline form and in its melting point. He calls it *euonymite.* (*Journ. de Pharm.,* Dec. 1862, 523.)

* For an examination of commercial *euonymin* (the eclectic resinoid) by Paul Thibault, see *N. R.,* 1883, 294.

Medical Properties and Uses. This bark was first introduced into notice, as a remedy for *dropsy*, under the name of Wahoo,* by Mr. George W. Carpenter. In some cases it acts as a mild cathartic, but at other times it fails to produce purgation. We have also seen distinct evidences of an irritant influence upon the gastro-intestinal mucous membrane. Cholagogue properties have been ascribed to it, and probably with correctness, as in the experiments of Prof. Rutherford it was found to act most powerfully in causing hepatic secretion in dogs, and in some clinical studies we have made it seemed to have a similar action on man. The fluid extract of it is an efficient preparation, and may be given in doses, as a purgative, of one to two fluidrachms (3·75–7·5 C.c.); as a laxative, of half a fluidrachm to one fluidrachm (1·9 –3·75 C.c.) (See also *Extractum Euonymi, U. S.*, and *Extractum Euonymi Siccum, Br.*)

EUPATORIUM. U.S. Eupatorium. [Thoroughwort.]

(EŪ-PA-TŌ′RI-ŬM—yū-pa-tō′ri-ŭm.)

"The leaves and flowering tops of Eupatorium perfoliatum, Linné (nat. ord. Compositæ)." *U. S.*

Herba Eupatorii Perfoliati; Boneset, Indian Sage; Herbe d'Eupatoire perfoliée, Herbe à Fièvre, Herbe parfaite, *Fr.;* Durchwachsener Wasserhanf, *G.*

Gen. Ch. Calyx simple or imbricate, oblong. *Style* long and semi-bifid. *Receptacle* naked. *Pappus* pilose, or more commonly scabrous. *Seed* smooth and glandular, quinquestriate. *Nuttall.*

Of this numerous genus, comprising not less than thirty species within the limits of the United States, most of which probably possess analogous medical properties, *E. perfoliatum* alone now holds a place in our national Pharmacopœia, *E. purpureum* and *E. teucrifolium* having been discarded at the revision of 1840. They merit, however, a brief notice, if only for their former official rank.

Eupatorium purpureum, or *gravel root*, is a perennial herbaceous plant, with a purple stem, five or six feet in height, and furnished with ovate-lanceolate, serrate, rugously veined, slightly scabrous, petiolate leaves, placed four or five together in the form of whorls. The flowers are purple, and consist of numerous florets contained in an eight-leaved calyx. It grows in swamps and other low grounds, from Canada to Virginia, and flowers in August and September. The root has, according to Dr. Bigelow, a bitter aromatic and astringent taste, and is said to be diuretic. Its vulgar name indicates the popular estimation of its virtues. Prof. J. U. Lloyd found in it an apparently new, yellow, neutral, crystalline principle, *euparin*. (*A. J. P.*, 1890.) This euparin, with a number of derivatives, has been prepared by C. C. Manger (*A. J. P.*, 1894, 120) and analyzed. The formula $C_{12}H_{11}O_3$ is given as its composition.

Eupatorium teucrifolium. (Willd. *Sp. Plant.* iii. 1753), *E. pilosum* (Walt. *Flor. Car.* 199), *E. verbenæfolium* (Mich. *Flor. Am.* ii. 98), commonly called *wild horehound*, is also an indigenous perennial, with an herbaceous stem, which is about two feet high, and supports sessile, distinct, ovate, acute, scabrous leaves, of which the lower are coarsely serrate at the base, the uppermost entire. The flowers are small, white, composed of five florets within each calyx, and arranged in the form of a corymb. The plant grows in low wet places from New England to Georgia, and abounds in the Southern States. It is in flower from August to November. The whole herb is used. In sensible properties it corresponds with *E. perfoliatum*, though less bitter and disagreeable, and has been used for similar purposes and in like manner. *E. incarnatum* and *E. aromaticum* are said to contain an aromatic principle similar to if not identical with coumarin, obtained by Guibourt from *Coumarouna odorata*, or Tonka bean. (See *P. J. Tr.*, Oct. 1874, 303.) The roots of *E. aromaticum* are said to be sold in the Western United States under the name of *white snakeroot*. *E. cannabinum*, of Europe, the root of which was formerly used as a purgative, and *E. aya-pana*, of Brazil, the leaves of which at one time enjoyed a very high reputation, have fallen into neglect. The *aya-pana* is an aromatic bitter, like *E. perfoliatum*, but weaker, and is said to be still occasionally met with in European commerce. (*A. J. P.*, 1887, 154; *Pharm. Era*, 1898, 293.) *E. villosum* is used in Jamaica, under the name of *bitter-bush*, in the preparation of beer, as a tonic, and as a stimulant in low zymotic diseases. (*P. J. Tr.*, Oct. 1866; *A. J. P.*, 1887, 155.) *E. collinum* is included in the Mexican Pharmacopœia.

Eupatorium perfoliatum. Willd. *Sp. Plant.* iii. 1761; Bigelow, *Am. Med. Bot.* i. 33; Barton, *Med. Bot.* ii. 125. *Thoroughwort*, or *boneset*, is an indigenous perennial plant, with

* The name of Wahoo or Waahoo (pronounced *Wawhoo*) was given to it by the Indians. The same name has also been applied to *Ulmus alata*, of the Southern States, and has thus led to mistakes.

numerous herbaceous stems, which are erect, round, hairy, from two to five feet high, simple below, and trichotomously branched near the summit. "Leaves opposite, united at the base, lanceolate, from 10 to 15 Cm. long, tapering, crenately serrate, rugosely veined, rough above, downy and resinous-dotted beneath; flower-heads corymbed, numerous, with an oblong involucre of lance-linear scales, and with from ten to fifteen white florets, having a bristly pappus in a single row; odor weak and aromatic; taste astringent and bitter." *U. S.* The leaves serve to distinguish the species at the first glance. They may be considered either as perforated by the stem, *perfoliate*, or as consisting each of two leaves, joined at the base, *connate*. In the latter point of view, they are opposite and in pairs, which decussate each other at regular distances upon the stem; in other words, the direction of each pair is at right angles with that of the pair immediately above or beneath it. They are narrow in proportion to their length, broadest at the base where they coalesce, gradually tapering to a point, serrate, much wrinkled, paler on the under than on the upper surface, and beset with whitish hairs, which give them a grayish-green color. The uppermost pairs are sessile, not joined at the base. The flowers are white, numerous, supported on hairy peduncles, in dense corymbs, forming a flattened summit. The calyx, which is cylindrical and composed of imbricated, lanceolate, hairy scales, encloses from twelve to fifteen tubular florets, having their border divided into five spreading segments. The anthers are five, black, and united into a tube, through which the bifid filiform style projects.

This species of Eupatorium inhabits meadows, the banks of streams, and other moist places, growing generally in bunches, and abounding in almost all parts of the United States. It flowers from the middle of summer to the end of October. All parts of it are active; but the herb only is official. It has a faint odor, and a strongly bitter, somewhat peculiar taste. The virtues of the plant are readily imparted to water and alcohol. Mr. W. Peterson found it to contain a peculiar bitter principle, chlorophyll, resin, a crystalline matter of undetermined character, gum, tannin, yellow coloring matter, extractive, lignin, and salts. (*A. J. P.*, xxiii. 210.) Mr. Bickley found also albumen, gallic acid, and signs of volatile oil. (*Ibid.*, xxvi. 495.) Dr. Peter Collier, chemist of the Department of Agriculture, recently submitted it to analysis, finding 18·84 per cent. of bitter extractive, which he considers the constituent of medicinal importance, 2·87 per cent. of an indifferent crystalline substance, obtained from the alcoholic extract, and traces only of a volatile oil. (*Ibid.*, 1879, p. 342.) George Latin (*A. J. P.*, Aug. 1880) found a glucoside, *eupatorin*, and a crystallizable body of the nature of a wax. O. F. Dana, Jr., obtained 3·80 per cent. of extract with benzin; 4·60 per cent. with ether; 33·80 per cent. with alcohol; 24·80 per cent. with water; 5·80 per cent. with alkali. (*A. J. P.*, 1887, p. 229.) A number of analyses of *E. perfoliatum* have been published in the last few years by Dana, Latin, Franz, and Kaercher, but neither the crystalline principle nor any of its salts had been analyzed until Shamel (*Amer. Chem. Journ.*, 1892, p. 224) published an analysis of the nitrate. He gives for it the formula $C_{20}H_{25}O_{36}HNO_3$.

Medical Properties and Uses. Eupatorium is tonic, diaphoretic, and in large doses emetic and aperient, and was at one time employed as an antiperiodic. Given in warm infusion, so as to produce vomiting or copious perspiration, at the commencement of catarrh, of influenza, or of that form of *muscular rheumatism* known as a general cold, it will sometimes abort the attack. As a tonic it is given with advantage in *dyspepsia*, general debility, and other cases in which the simple bitters are employed. Dr. H. S. Wilkins has found the infusion useful in the expulsion of *tapeworm*. (*A. J. P.*, 1874, p. 295.)

With a view to its tonic effects, it is best administered in substance, or cold infusion. The dose of the powder is twenty or thirty grains (1·3–1·95 Gm.), that of the infusion a fluidounce (30 C.c.), frequently repeated. (See *Infusum Eupatorii*.) The aqueous extract has been used with advantage. When the diaphoretic operation is required in addition to the tonic, the infusion should be administered warm, and the patient remain covered in bed. As an emetic and cathartic, a strong decoction, prepared by boiling an ounce with three half-pints of water to a pint, may be given in doses of from four fluidounces to a half-pint (118 to 236 C.c.), or more. (See *Extractum Eupatorii Fluidum*.)

EXTRACTA. Extracts.

(ĘX-TRĂC'TĄ.)

Extraits, *Fr.*; Extrakte, *G.*

Extracts, as the term is employed in the Pharmacopœias, are solid preparations, resulting from the evaporation of the solutions of vegetable principles, obtained either by exposing a

dried drug to the action of a solvent, or by expressing the juice from a fresh plant. A distinction was formerly made between those prepared from the infusions, decoctions, or tinctures, and those from the expressed juices of plants, the former being called *Extracta*, the latter *Succi Spissati;* but the distinction has been generally abandoned. There is no such essential difference between these two sets of preparations as to require that they should be separately classed; and something is gained in the simplicity of nomenclature, as well as of arrangement, which results from their union. We shall consider them under the same head, taking care, however, to detail distinctly whatever is peculiar in the mode of preparing each.

The composition of extracts varies with the nature of the vegetable, the character of the solvent, and the mode of preparation. The object is generally to obtain as much of the active principle of the plant with as little of the inert matter as possible; though sometimes it may be desirable to separate two active ingredients from each other, when their effects upon the system are materially different; and this may be accomplished by employing a menstruum which, while it dissolves one, leaves the other untouched. The proximate principles most commonly present in extracts are gum, sugar, starch, tannin, extractive, coloring matter, salts, and the peculiar principles of plants; to which, when a spirituous solvent is employed, may usually be added resinous substances, fatty matter, and frequently more or less essential oil; gum and starch being excluded when the menstruum is pure alcohol. Of these substances, as well as of others which, being soluble, are sometimes necessarily present in extracts, we have taken occasion to treat under various heads in this commentary. There is one, however, which, from its supposed almost uniform presence in this class of preparations, and from the influence it is thought to exert upon their character, deserves particular consideration in this place. We allude to *extractive*, or, as it is sometimes called, *extractive matter*.

It has long been observed that in most vegetables there is a substance, soluble both in water and alcohol, which, in the preparation of extracts, undergoes chemical change during the process of evaporation, imparting to the liquid, even if originally limpid, first a greenish, then a yellowish brown, and ultimately a deep brown color, and becoming itself insoluble. This substance, originally called *saponaceous matter* by Scheele, afterwards received the more expressive name of *extractive*, derived from its frequent presence in extracts. Its existence as a distinct principle is denied, or at least doubted, by some chemists, who consider the phenomena supposed to result from its presence as depending upon the mutual reaction of other principles; and in relation to Peruvian bark it appears to have been proved that the insoluble matter which forms during its decoction in water is a compound of starch and tannin. A similar compound must also be formed in other cases when these two principles coexist; but they are not always present in the same vegetable, nor can all the changes which have been attributed to extractive be accounted for by their union, even when they are present; so that, until further light is shed on the subject, it is best to admit the existence of a distinct class of substances, which, though not the same in all plants, possess sufficient identity of character to be entitled, like sugars, resins, etc., to a generic name. The most important property of extractive is its disposition to pass, by the influence of atmospheric air at a high temperature, into an insoluble substance. If a vegetable infusion or decoction be evaporated in the open air to the consistence of an extract, then diluted, filtered, and again evaporated, and the process repeated so long as any insoluble matter is formed, the whole of the extractive will be separated from the liquid, while the other ingredients may remain. If chlorine be passed through an infusion or decoction, a similar precipitate is formed with much greater rapidity. The change is usually ascribed to the absorption of oxygen by the extractive, which has, therefore, been called, in its altered condition, oxidized extractive; but De Saussure ascertained that, though oxygen is absorbed during the process, an equal measure of carbonic acid gas is given out, and the oxygen and hydrogen of the extractive unite to form water in such a manner as to leave the principle richer in carbon than it was originally. The name of oxidized extractive is, therefore, obviously incorrect; and Berzelius proposed to substitute for it that of *apotheme*, synonymous with deposit. According to Berzelius, apotheme is not completely insoluble in water, but imparts a slight color to that liquid when cold, and is rather more soluble in boiling water, which becomes turbid upon cooling. It is still more soluble in alcohol, and is freely dissolved by solutions of the alkalies and alkaline carbonates, from which it is precipitated by acids. It has a great tendency, when precipitated from solutions, to unite with other principles, and to carry them along with it, thus acquiring properties somewhat different according to the source from which it is obtained. In this way also, even when the extractive of a plant is itself medicinally inert, its conversion into apotheme may be injurious by causing a precipi-

tation of a portion of the active principle; and in practical pharmaceutical operations this change should always, if possible, be avoided. With these preliminary views, we shall proceed to the consideration of the practical rules necessary to be observed in the preparation of extracts. We shall treat of the subject under the several heads of—1, the extraction of the soluble principles from the plant; 2, the method of conducting the evaporation; 3, the proper condition of extracts, the changes they are liable to undergo, and the best method of preserving them.

1. *Extraction of the Soluble Principles.*

There are two distinct modes of obtaining, in a liquid state, the principles which we wish to extract: 1, by expression alone; 2, by the agency of a solvent, with or without expression.

1. By Expression. This method is applicable to recent vegetables. All plants cannot be usefully treated in this way, as many have too little juice to afford an appreciable quantity upon pressure, and of the succulent a considerable portion do not yield all their active principles with their juice. Succulent fruits, and various acrid and narcotic plants, are proper subjects for this treatment. The plants should be operated upon, if possible, immediately after collection. Mr. Battley, of London, recommended that, if not entirely fresh, they should be revived by the immersion of the stalks in water for twelve or eighteen hours, and those only used which recover their freshness by this management. They should then be cut into pieces, and bruised in a stone mortar till brought to a pulpy consistence. When the plant is not very succulent, it is necessary to add a little water during this part of the process, in order to dilute the juice. After sufficient contusion, the pulp is introduced into a linen or canvas bag, and the liquid parts expressed. Mr. Brande states that light pressure only should be employed, as the extract is thus procured greener, of a less glutinous or viscid consistence, and, in his opinion, more active than when considerable force is used in the expression. (*Practice of Pharmacy.*) The juice thus obtained is opaque, and usually green, in consequence of the presence of green wax or chlorophyll, and of a portion of the undissolved vegetable fibre in minute division. By heating the juice to about 71·1° C. (160° F.) the albumen contained in it coagulates, and, involving the chlorophyll and vegetable fibre, forms a greenish precipitate. If the liquid be now filtered, it becomes limpid and nearly colorless, and is prepared for evaporation. The clarification, however, is not absolutely necessary, and is generally neglected. Sometimes the precipitate carries with it a considerable portion of the active principle; in which case it should be subsequently incorporated with the juice, when reduced by evaporation to the consistence of syrup.* Ether added to the expressed juices of plants enables them to be kept long without injurious change. M. Lepage, of Gisors, France, has kept the juice of belladonna in this way more than ten years, and found it, at the end of that time, to yield an extract identical in physical, chemical, and physiological properties with that obtained from the fresh juice. If this fact is found to be of general applicability, it will be of considerable importance, as enabling the pharmaceutist to supply himself at pleasure with extracts to be relied on, without reference to the season.

2. By Solution. The active principles of dried vegetables can be extracted only by means of a liquid solvent. The menstruum usually employed is either water or alcohol, or a mixture of the two. Water, on account of its cheapness, is always preferred, when circumstances do not strongly call for the use of alcohol. It has the advantage, moreover, that it may be assisted in its action, if necessary, by a higher degree of heat than the latter. Pump water is often unfit for the purpose, in consequence of the quantity of its saline matter, which in some instances may exert an unfavorable influence on the active principle, and must always be left in the extract. Rain, river, or distilled water should be preferred. Alcohol is employed when the principles to be extracted are insoluble or but slightly soluble in water, as in the case of the resins; when it is desirable to avoid in the extract inert substances, such as gum and starch, which are dissolved by water and not by alcohol; when the heat required to evaporate the aqueous solution would dissipate or decompose the active ingredients of the plant, as the volatile oils or the active principle of sarsaparilla; when the reaction of the water itself upon the vegetable principles is injurious; and, finally, when the nature of the substance to be exhausted requires so long a maceration in water as to endanger spontaneous decomposition. The aqueous solution requires to be soon evaporated, as this fluid rather promotes than counteracts chemical changes; while an alcoholic tincture may be preserved unaltered for an indefinite period. An addition of alcohol to water is sufficient to answer some of the purposes for which the former

* See the process for inspissated juices under Extractum Belladonnæ, *Br.*, p. 545.

is preferable; and the employment of both fluids is essential, when the virtues of the plant reside in two or more principles, all of which are not soluble in either of these menstrua. In this case it is usually better to submit the vegetable to the action of the two fluids successively than of both united. Extracts obtained by the agency of water are called *aqueous extracts;* those by means of alcohol, undiluted or diluted, *alcoholic* or *spirituous extracts.* Sometimes the term *hydro-alcoholic* is applied to extracts obtained by the joint agency of alcohol and water.

The method of preparing the solution is not a matter of indifference. The drug should be thoroughly bruised, or reduced to a coarse powder, so as to allow the access of the solvent to all its parts, and yet not so finely pulverized as to prevent a ready precipitation of the undissolved and inactive portion. When water is alone employed, it has been customary to boil the medicine for a considerable time, and, if the first portion of liquid does not completely exhaust it, to repeat the operation with successive portions till the whole of the active matter is extracted. This may be known by the sensible properties of the liquid, and by its influence upon reagents. But the boiling temperature produces the decomposition of many vegetable principles, or at least so modifies them as to render them inert; and the extracts prepared by decoction are usually less efficient than those made with a less degree of heat. From numerous experiments upon extracts, Orfila concluded that their virtues were less in proportion to the heat employed. It has, therefore, been recommended to substitute for decoction the process of maceration, digestion, or hot infusion; in the first of which the liquid acts without heat, in the second is assisted by a moderately increased temperature sustained for a considerable time, and in the third is poured boiling hot upon the vegetable matter and allowed to stand for a short period in a covered vessel. When the active principles are readily soluble in cold water, *maceration* is often preferable to the other modes, as starch, which is inert, is thus left behind; but in many instances the preparation would spoil before the extraction would be completed. By *digestion*, though the solvent power of water is moderately increased, the advantage is often more than counterbalanced by the increased disposition to spontaneous decomposition. *Hot infusion*, therefore, is to be preferred where the vegetable does not readily yield its virtues to cold water. It has the advantage, moreover, in the case of albuminous substances, that the albumen is coagulated, and thus prevented from increasing the bulk of the extract, without adding to its virtues. A convenient mode of performing this process is to introduce the solid material into a vessel with an opening near the bottom temporarily closed, or into a funnel with its mouth loosely stopped, then to pour on the boiling water, and, having allowed it to remain a sufficient length of time, to draw it off through the opening. This operation may be repeated till the water comes away without any obvious impregnation. It is always desirable to obtain the solution in the first place as concentrated as possible, so as to prevent the necessity of long-continued evaporation, which injures the extract. It is better, therefore, to incur the risk, both when decoction and infusion are employed, of leaving a portion of the active matter behind, than to obtain a very weak solution. When successive portions of water are employed, those which are least impregnated should be brought by evaporation to the strength of that first obtained before being mixed with it, as the latter thus escapes unnecessary exposure to heat.

Sometimes the filtering of a turbid infusion or decoction, before evaporation, causes the resulting extract to keep better, by removing substances which, besides undergoing decomposition, may act as a ferment, and occasion the decomposition of the active matter of the extract.

When alcohol is employed as a menstruum, the vegetable should be macerated in it for one or two weeks, and care should be taken that the tincture be as nearly saturated as possible. The extraction may be hastened by substituting digestion for maceration; as the moderate heat employed, while it facilitates the action of the alcohol, has in this case no effect in promoting decomposition, and the influence of the atmospheric air may be excluded by performing the process in close vessels. When alcohol and water are both used, it is best, as a rule, to exhaust the substance with each separately, as the two menstrua require different modes of treatment. In whichever of these modes the extraction is effected, it requires the assistance of occasional agitation; and when the vegetable matter is very porous, and absorbs a large quantity of the solvent, expression must be resorted to.

Acetic acid has been introduced into use as a menstruum in the preparation of extracts. It is supposed to be a better solvent of the active principles of certain substances than either water or alcohol alone. According to Girolamo Ferrari, the acrid narcotics, such as aconite, hemlock, hyoscyamus, and stramonium, yield much stronger extracts with distilled vinegar than with water, and still stronger with alcohol to which strong acetic acid has been added. (*Journ. de Pharm.*, 3e sér., i. 239.) This acid is used in the preparation of the extract of

colchicum. Recent experiments have shown that strong acetic acid (60 per cent.) is a powerful solvent for the active properties of various drugs, particularly those which contain volatile oils, and in many cases a 10 per cent. acetic acid is an excellent menstruum for making extracts; for these the name *acetract* has been proposed. (*Proc. A. P. A.*, 1897, 416.) Dr. E. R. Squibb has used acetic acid largely for extracts. (*West. Drug.*, 1897, 123.)

Ether also is now used to a considerable extent in the preparation of certain extracts. Having the property of dissolving volatile oil and resin, and of evaporating at a temperature insufficient to volatilize the oil, it is admirably adapted for the preparation of extracts from those substances the virtues of which reside in the two principles referred to. An ethereal tincture is first prepared by the process of percolation, and the ether is then either allowed to escape by spontaneous evaporation, or distilled off at a very moderate heat. The oleoresinous extracts thus obtained are usually of a thick fluid or semi-fluid consistence. Several of them are now ranked among the official preparations, in the U. S. Pharmacopœia, under the title of *Oleoresins*.

The process of *percolation* has in this country been very advantageously applied to the preparation of extracts, both with water and spirituous menstrua. It has the following great advantages: 1, that it enables the soluble principles to be sufficiently extracted by cold water, thereby avoiding the injury resulting from heat in decoction and hot infusion; 2, that it effects the extraction much more quickly than can be done by maceration, thereby not only saving time, but also obviating the risk of spontaneous decomposition; and, 3, that it affords the opportunity of obtaining highly concentrated solutions, thus diminishing the injurious effects of the subsequent evaporation. While thus advantageous, it is less liable in this particular case than in others to the objection of yielding imperfect results if not well performed; for, though an inexpert or careless operator may incur loss by an incomplete exhaustion of the substance acted on, and the extract may be deficient in quantity, it may still be of the intended strength and quality, which is not the case with infusions or tinctures unskilfully prepared upon this plan. In the U. S. Pharmacopœia, all the extracts to which the process is applicable are prepared by percolation, and with merely sufficient previous maceration or digestion to thoroughly soften the extractive. In the British Pharmacopœia, the process is applied, as it were, hesitatingly to a portion of the extracts, and withheld in others to which it seems equally appropriate. The first requisite in performing the process of percolation is to have the drug reduced to the proper degree of fineness. The U. S. Pharm. gives the following directions on the subject.

Fineness of Powder. "The fineness of powder is expressed, in the Pharmacopœia, either by descriptive words (generally so in the case of brittle or easily pulverizable substances), or in terms expressing the number of meshes to a linear inch of the sieve through which the powder will pass. The corresponding values, in terms of metric measures of length, are added below in parentheses, but it has not been deemed advisable, in this revision, to substitute them in the text of the Pharmacopœia for those at present in use.

"These different forms of expression correspond to each other as follows:

A *very fine* powder	should pass through a sieve having 80 or more meshes to the linear inch (30 meshes to the centimeter)	= No. 80 powder.
A *fine* powder	should pass through a sieve having 60 meshes to the linear inch (24 meshes to the centimeter)	= No. 60 powder.
A *moderately fine* powder	should pass through a sieve having 50 meshes to the linear inch (20 meshes to the centimeter)	= No. 50 powder.
A *moderately coarse* powder	should pass through a sieve having 40 meshes to the linear inch (16 meshes to the centimeter)	= No. 40 powder.
A *coarse* powder	should pass through a sieve having 20 meshes to the linear inch (8 meshes to the centimeter)	= No. 20 powder.

"In certain cases, powders of a different degree of fineness (*e.g.*, No. 30, No. 12) are directed to be taken. When a substance is directed to be in powder of a limited degree of fineness, as

specified by the number of meshes to the linear inch in the sieve, not more than one-fourth of the powder should pass through a sieve having ten meshes more to the linear inch." *U. S.*

Percolation. "The process of percolation, or displacement, directed in this Pharmacopœia, consists in subjecting a substance or a mixture of substances, in powder, contained in a vessel called a percolator, to the solvent action of successive portions of a certain menstruum in such a manner that the liquid, as it traverses the powder in its descent to the receiver, shall be charged with the soluble portion of it, and pass from the percolator free from insoluble matter.

"When the process is successfully conducted, the first portion of the liquid, or percolate, passing through the percolator, will be nearly saturated with the soluble constituents of the substance treated; and if the quantity of menstruum be sufficient for its exhaustion, the last portion of the percolate will be nearly free from color, odor, and taste, other than those of the menstruum itself.

"The percolator most suitable for the quantities contemplated by this Pharmacopœia should be nearly cylindrical, or slightly conical, with a funnel-shaped termination at the smaller end. The neck of this funnel-end should be rather short, and should gradually and regularly become narrower towards the orifice, so that a perforated cork, bearing a short glass tube, may be tightly wedged into it from within until the end of the cork is flush with the outer edge of the orifice. The glass tube, which must not project above the inner surface of the cork, should extend from 3 to 4 Cm. beyond the outer surface of the cork, and should be provided with a closely fitting rubber tube, at least one-fourth longer than the percolator itself, and ending in another short glass tube, whereby the rubber tube may be so suspended that its orifice shall be above the surface of the menstruum in the percolator, a rubber band holding it in position.

"The shape of a percolator should be adapted to the nature of the drug to be operated upon. For drugs which are apt to swell, particularly when a feebly alcoholic or an aqueous menstruum is employed, a *conical* percolator is preferable. A *cylindrical* or only slightly tapering percolator may be used for drugs which are not liable to swell, and when the menstruum is strongly alcoholic, or when ether or some other volatile liquid is used for extraction. The size of the percolator selected should be in proportion to the quantity of drug extracted. When properly packed in the percolator, the drug should not occupy more than two-thirds of its height. The percolator is best constructed of glass or stone-ware, but, unless otherwise directed, may be made of any suitable material not affected by the drug or menstruum.

"The percolator is prepared for percolation by gently pressing a small tuft of cotton into the neck above the cork, a thin layer of clean and dry sand being then poured upon the surface of the cotton to hold it in place.

"The powdered substance to be percolated (which must be uniformly of the fineness directed in the formula, and should be perfectly air-dry before it is weighed) is put into a basin, the specified quantity of menstruum is poured on, and it is thoroughly stirred with a spatula, or other suitable instrument, until it appears uniformly moistened. The moist powder is then passed through a coarse sieve—No. 40 powders, and those which are finer, requiring a No. 20 sieve, whilst No. 30 powders require a No. 15 sieve for this purpose. Powders of a less degree of fineness usually do not require this additional treatment after the moistening. The moist powder is now transferred to a sheet of thick paper and the whole quantity poured from this into the percolator. It is then shaken down lightly and allowed to remain in that condition for a period varying from fifteen minutes to several hours, unless otherwise directed; after which the powder is pressed, by the aid of a plunger of suitable dimensions, more or less firmly, in proportion to the character of the powdered substance and the alcoholic strength of the menstruum; strongly alcoholic menstrua, as a rule, permitting firmer packing of the powder than the weaker. The percolator is now placed in position for percolation, and, the rubber tube having been fastened at a suitable height, the surface of the powder is covered by an accurately fitting disk of filtering paper, or other suitable material, and a sufficient quantity of the menstruum poured on through a funnel reaching nearly to the surface of the paper. If these conditions be accurately observed, the menstruum will penetrate the powder equally until it has passed into the rubber tube and has reached, in this, a height corresponding to its level in the percolator, which is now closely covered to prevent evaporation. The apparatus is then allowed to stand at rest for the time specified in the formula.

"To begin percolation, the rubber tube is lowered and its glass end introduced into the neck of a bottle previously marked for the quantity of liquid to be percolated, if the percolate is to be measured, or of a tared bottle, if the percolate is to be weighed; and by raising

or lowering this receiver the rapidity of percolation may be increased or decreased as may be desirable, care being taken, however, that the rate of percolation, unless the quantity of material be largely in excess of the pharmacopœial quantity, shall not exceed the limit of ten to thirty drops in a minute. A layer of menstruum must constantly be maintained above the powder, so as to prevent the access of air to its interstices, until all has been added, or the requisite quantity of percolate has been obtained. This is conveniently accomplished, if the space above the powder will admit of it, by inverting a bottle containing the entire quantity of menstruum over the percolator in such a manner that its mouth may dip beneath the surface of the liquid, the bottle being of such shape that its shoulder will serve as a cover for the percolator. When the dregs of a tincture, or of a similar preparation, are to be subjected to percolation, after maceration with all or with the greater portion of the menstruum, the liquid portion should be drained off as completely as possible, the solid portion packed in a percolator, as before described, and the liquid poured on, until all has passed from the surface, when immediately a sufficient quantity of the original menstruum should be poured on to displace the absorbed liquid, until the prescribed quantity has been obtained.

"*Repercolation.* Authority is given to employ, in the case of Fluid Extracts, where it may be applicable, the process of Repercolation, without change of the initial menstruum." *U. S.*

For an account of Dr. Squibb's process of repercolation, see *Extracta Fluida*.

Some prefer the mode of expression to that of percolation. This also is applicable both to aqueous and to alcoholic menstrua. The substance to be acted upon is mixed with the menstruum, cold or hot according to circumstances; and the mixture is allowed to stand from twelve to twenty-four hours. The liquid part is then filtered off, and the remainder submitted to strong pressure, in a linen bag, by means of a common screw-press, or other convenient instrument. Another portion of the menstruum may then be added, and pressure again applied, and, if the substance is not sufficiently exhausted, the same operation may be performed a third time. Frequently only a single expression is required, and very seldom a third. The quantity of menstruum added must vary with the solubility of the principles to be extracted. According to Mohr, the method of expression has the advantages over that of percolation, that it yields solutions of more uniform concentration, that it does not require the materials to be so carefully powdered, or otherwise so skilfully managed, in order to insure favorable results, and, finally, that it occupies less time.

2. *Mode of Conducting the Evaporation.*

In evaporating the solutions obtained in the modes above described, attention should always be paid to the fact that the extractive matter is constantly becoming insoluble at high temperatures with the access of air, and that other chemical changes are going on, sometimes not less injurious than this, while the volatile principles are expelled with the vapor. The operator should, therefore, observe two rules: 1, to conduct the evaporation at as low a temperature as is consistent with other objects; 2, to exclude atmospheric air as much as possible, and, when this cannot be accomplished, to expose the liquid the shortest possible time to its action. The injurious influence of atmospheric air is much greater at the boiling point of water than at a less heat, even allowing for the longer exposure in the latter case; and therefore a slow evaporation at a moderate heat is preferable to the more rapid effects of ebullition. Bearing these principles in mind, we shall proceed to examine the different modes in practice. First, however, it is proper to observe that decoctions generally let fall, upon cooling, a portion of insoluble matter; and it is a question whether this should be rejected, or retained so as to form a part of the extract. Though it is undoubtedly in many instances inert, as in that of the insoluble substance formed during the decoction of certain vegetable substances, yet, as it frequently also contains a portion of the active principle which a boiling saturated solution necessarily deposits on cooling, and as it is difficult to decide with certainty when it is active and when otherwise, the safest plan, as a rule, is to allow it to remain.

The method of evaporation formerly resorted to in the case of aqueous solutions is rapid boiling over a fire. The more quickly the process is conducted, the better, provided the liquid is to be brought to the boiling point; for the temperature cannot exceed this, and the length of exposure is diminished. But, where this method is employed, it should never be continued till the completion of the evaporation; for when most of the water has escaped, the temperature can no longer be kept down to the boiling point, and the extract is burnt. The caution, therefore, should always be observed of removing the preparation from the fire before it has attained the consistence of thick syrup, and completing the evaporation, either by means of a

water-bath, or in shallow vessels at a moderate heat. When large quantities of liquid are to be evaporated, it is best to divide them into portions and evaporate each separately, for, as each portion requires less time for evaporation than the whole, it will thus be a shorter time exposed to heat. (*Mohr.*) But the mode of evaporation by boiling is always objectionable, and should be employed only in cases where the principles of the plant are so fixed and unchangeable as to authorize their extraction by decoction.

Evaporation by means of the water-bath, from the commencement of the process, is safer than the plan just mentioned, as it obviates all danger of burning the extract; but, as the heat is not supplied directly from the fire, the volatilization of the water cannot go on so rapidly, and, the temperature being nearly the same, when the water-bath is kept boiling, there is greater risk of injurious action from the air. The liquid should be stirred during the process. The use of the steam-bath has become very general in this country, as it requires a smaller consumption of fuel, and the heat imparted to the liquid, while sufficient to evaporate it, is less than 100° C. (212° F.). The apparatus consists of an ordinary boiler, containing water, the vapor of which is conducted through a pipe into the evaporating vessels, communicating with each other by means of iron steam pipes. These vessels have the form of an ordinary copper basin, to the inside of which is riveted a shallow tinned copper evaporating basin, intended to contain the liquid to be evaporated. The vapor from the boiler circulates between these vessels, and the water into which it condenses is allowed to escape through a steam valve attached to the bottom of each vessel. The liquid to be evaporated is first distributed in two or three basins, but when considerably concentrated is transferred to a single one, where it is stirred towards the close of the process to hasten the evaporation. The heat applied to the liquid can be easily regulated by the steam valves.

As the heat capable of being applied by boiling water to the evaporating liquid does not exceed 93·3° C. (200° F.), while that by steam can, by a moderate pressure, be increased to the boiling point or beyond it, the evaporation by the latter agency may be much more rapid than by the former, when the pressure is from ten to twenty pounds to the square inch; so that there is a temptation to raise the heat to a degree seriously injurious to the product. Evaporation, therefore, by steam heat always requires caution, while the water-bath is much less liable to be abused. In this respect the latter method has the advantage.

A good plan of evaporation, though slow, is to place the liquid in a broad, shallow vessel, exposed in a stove or drying-room to a temperature of about 100° F., or a little higher, taking care that the air have free access in order to facilitate the evaporation. This mode is particularly applicable to those cases in which maceration or infusion is preferred to decoction for extracting the active principles. Berzelius says that we may thus usually obtain the extract in the form of a yellowish transparent mass, while extracts prepared in the ordinary way are almost black, and are opaque even in very thin layers. Even when the liquid is boiled at first, the process may often be advantageously completed in this manner. It has been proposed to effect the evaporation at the common temperature, by directing a strong current of air, by means of a pair of smith's bellows, over the surface of the liquid; and in reference to substances which are injured by heat and not by atmospheric air the plan will be found useful.

Plans have been proposed and carried into execution for performing evaporation without the admission of atmospheric air. The apparatus for *evaporation in vacuo*, now largely used by manufacturing pharmacists, is well calculated to meet this object, at the same time that, by removing the atmospheric pressure, it enables the water to rise in vapor more rapidly, and at a comparatively low temperature.*

A convenient plan of excluding the air, though it does not at the same time meet the object of reducing the degree of heat, is to distil off the water in close vessels. Berzelius says that this is the best mode of concentration next to that *in vacuo*. Care, however, must be taken that the fire be not too long applied, lest the extract should be burnt. The process should, therefore, be completed by means of the water-bath.

* A very ingenious apparatus for evaporating *in vacuo* on a small scale has been invented by Prof. A. B. Prescott (*A. J. P.*, xlii. 349). Two vessels are required: a small one, for evaporation; a large one, which is best made of copper, and should be so arranged as to be readily heated or refrigerated at will. The two are to be connected by glass tubing, through rubber corks, and into the cork of the evaporating dish is to be set a short straight glass tube with a piece of rubber tubing fitted to it so that it can be tightly closed with a glass rod at will. An ounce or two of water having been put in the receiver, and the material in the evaporating vessel, a gentle heat is, by means of water, applied to the evaporating vessel, but a strong heat to the receiver. The water in this latter boils furiously, and the vapor escapes through the opened tube in the evaporating vessel. When the water is exhausted the tube is closed and the receiver refrigerated. Of course a vacuum results, and is maintained by the continuous condensation of vapor in the receiver.

In the concentration of alcoholic solutions, distillation should always be performed, as not only is the atmospheric air thus excluded, but the alcohol is recovered, if not absolutely pure, certainly fit for the purpose to which it was originally applied. Here also the water-bath should be employed, to obviate any possible risk of injury from the fire. When the decoction or infusion and the tincture of the same vegetable have been made separately, they should be separately evaporated to the consistence of syrup, and then mixed together while they are of such a consistence as to incorporate without difficulty. The object of this separate evaporation is that the spirituous extract may not be exposed to the degree of heat, or lengthened action of the air, which is necessary in the ordinary mode of concentrating the infusion or decoction.

In every instance, care should be taken to prevent any portion of the extract from becoming dry and hard on the sides of the evaporating vessel, as in this state it will not readily incorporate with the remaining mass. The heat, therefore, should be applied to the bottom and not to the sides of the vessel.

Inasmuch as the yield of extracts is largely dependent on the character of the menstruum used in the percolation, it follows that there must necessarily be a great variation in the strength of commercial extracts. C. H. Lawall has prepared a valuable table giving the yield of extract by various drugs. (*Proc. A. P. A.*, 1897, 414.) For methods of assay, see *Proc. A. P. A.*, 1897, 415.

3. *Condition and Preservation of Extracts.*

Extracts may be prepared of two different degrees of consistence: soft so that they may be readily made into pills, and hard in order that they may be pulverized. The soft extracts always contain a notable percentage of water. In astringent extracts, the evaporation should be carried to dryness. Those obtained from the expressed juices of plants are apt to attract moisture from the air, in consequence of the deliquescent nature of the salts existing in the juice. They are thus rendered softer, and more liable to become mouldy upon the surface. Others, especially such as contain much chlorophyll, harden by time, in consequence of the escape of their moisture; and it not unfrequently happens that small crystals of saline matter are formed in their substance; sodium chloride in small cubes is sometimes found in certain old extracts, having slowly crystallized as they hardened. Prof. John Attfield, of London, has made a chemical examination of the crystals found in numerous extracts, and ascertained that in a large number they consisted of potassium chloride, and in a comparatively few of potassium nitrate.* The air, moreover, exercises an unfavorable chemical influence over the softer extracts, which are enfeebled, and ultimately become nearly inert, by the same changes which they undergo more rapidly in the liquid state at an elevated temperature. If an extract be dissolved in water, and the liquid be saturated with common salt or any other very soluble salt of difficult decomposition, the greater part of it will be precipitated, in consequence of the insolubility of this class of substances in saline solutions. The precipitate may be again dissolved in pure water.

Abstracts, which were official in the U. S. P. 1880, were not re-introduced into the present revision, as they did not come into general use: this is unfortunate, as they had many advantages, and as they are used in certain sections of the country. A description and a typical formula, with comments, are appended.† Abstracts of the following eleven drugs were official

* Thus, potassium chloride was detected in the extracts of belladonna, hemlock, sarsaparilla (compound), colchicum seeds, stramonium seeds, and aconite; potassium nitrate in the extracts of belladonna, hyoscyamus, and lettuce; and sodium sulphate in extract of stramonium seeds. (*P. J. Tr.*, March, 1862, p. 448.)

† Abstracta. *Abstracts.* Abstracts are solid powdered preparations containing the soluble constituents of the drugs from which they are made, and to which they bear a definite and uniform relation. These preparations were first introduced into the U. S. Pharmacopœia of 1880, and have many advantages over ordinary extracts. They are prepared by evaporating an alcoholic tincture of a drug spontaneously and at a low temperature, mixing it with a sufficient quantity of dried sugar of milk to make the final product when dry weigh one-half the weight of the drug, and then powdering it. The following general formula exhibits the typical official process.

General Formula. Drug, in No. 60 powder, *two hundred parts* [or four ounces av.]: Sugar of Milk, recently dried and in fine powder, Alcohol, each, *a sufficient quantity*, To make *one hundred parts* [or two ounces av.]. Moisten the drug with *eighty parts* [or one and three-quarter fluidounces] of Alcohol, and pack firmly in a cylindrical glass percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the drug is exhausted. Reserve the first *one hundred and seventy parts* [or three and one-half fluidounces] of the percolate, evaporate the remainder to *thirty parts* [or half a fluidounce] at a temperature not exceeding 50° C. (122° F.), and mix with the reserved portion. Place the mixture in an evaporating dish, and, having added *fifty parts* [or one ounce av.] of Sugar of Milk, cover it with a piece of thin muslin gauze, and set aside in a warm place, where the temperature will not rise above 50° C. (122° F.), until the mixture is dry. Lastly, having added enough Sugar of Milk to make the mixture

in 1880: aconite, belladonna root, conium, digitalis, hyoscyamus, ignatia, jalap, nux vomica, podophyllum, senega, and valerian. Prof. Hallberg favors the use of a menstruum of three measures of alcohol with one of chloroform for abstracts, and prefers the term "*quatract*" to "*abstract.*" (*Proc. A. P. A.*, 1894, 245.)

Extracts, in order that they may keep well, should be placed in glazed earthenware, glass, or porcelain jars, and completely protected from the access of the air. This may be effected by covering their surface with a layer of melted wax, or with a piece of paper moistened with strong spirit, then closing the mouth of the vessel with a cork, spreading wax or rosin over this, and covering the whole with leather or a piece of bladder. (*Duncan.*) The dry extracts, being less liable to be affected by atmospheric oxygen, do not require so much care. The application of alcohol to the surface has a tendency to prevent mouldiness. A method of protecting extracts from the action of the air, frequently resorted to, is to cover them closely with oiled bladder; but this, though better than to leave them uncovered, is not entirely effectual. Should the extract become too moist, it may be dried by means of a water-bath; should it, on the contrary, be too dry, the proper consistence may be restored by softening it in the same manner and incorporating with it a little distilled water. Martin (1880) proposes to preserve extracts in a soft condition by surrounding the vessel containing the extract by another of larger diameter, which is furnished with a tight cover, the space between the two vessels being filled with crystallized sodium sulphate, which gradually parts with its water of crystallization and prevents the extract from becoming hard and dry.

When extracts which are too soft are subjected to a moderate temperature, fermentation may set in: E. Cocardas describes the various forms of "Penicillium-ferment" which grow in such extracts, and concludes that the ferment causes them to undergo changes similar to those effected by heat,—viz., the absorption of oxygen and the disengagement of carbon dioxide. (*P. J. Tr.*, 1886, p. 590.)

Some extracts when powdered have a tendency to cohere again. According to Geiseler, this may be obviated by the addition of sugar of milk or powdered liquorice-root; two or three parts of the former and one part of the latter to one of the extract being sufficient for the purpose. (*Pharm. Centralbl.*, 1850, p. 238.) Mohr recommends the following plan of drying and preserving extracts. Take equal parts of powdered liquorice-root and of the extract, rub them well together in a mortar, put the resulting paste into an earthen vessel with a flat bottom, place this in another of iron, a little deeper, containing calcium chloride thoroughly dried by heat insufficient to melt it; then enclose the whole with a cover fitted to the iron vessel, and allow them to stand for a day or more. When the mixture is quite dry, powder it, and add so much of the powdered root as to make the weight double that of the original extract.* (*Ibid.*, p. 119.) Four parts of extract are now mixed with three parts of finely powdered liquorice-root, and dried in a porcelain capsule at 40°–50° C. (104°–122° F.) until the mixture ceases to lose weight. The mass is then rubbed to powder, and sufficient powdered liquorice-root added to make the whole weigh eight parts, or double the weight of extract used. In our opinion, this method is not so good as that formerly adopted for abstracts. The German powdered extracts are always half the strength of the extracts, no relation whatever with the drug is established, and the variations in the yield of extract from different drugs have been repeatedly shown to be great. Kirchmann proposes exsiccated sodium sulphate as a diluent instead of dextrin, liquorice-root, etc. (*Pharm. Zeitung*, 1881, 116.) Dr. A. B. Lyons, of Detroit (1898), has introduced *scale extracts.* These do not, as a class, bear a definite relation to the drug; they are assayed, however, and acacia is used as a means of preserving their dry condition; they are easily pulverized, and are very convenient for dispensing.

The plan of incorporating a little glycerin with extracts has been recommended for such

weigh *one hundred parts* [or two ounces av.], reduce it to a fine, uniform powder. Preserve the powder in a well-stopped bottle.

The advantages possessed by abstracts may be briefly stated as follows:

1. Each abstract represents twice the strength of the drug or fluid extract from which it is prepared.

2. They are dry powders, if properly made, and thus are permanent and portable; not subject to precipitation as fluid extracts are; not liable to become hard, tough, and variable in strength, as is the case with extracts.

3. Injurious exposure to heat is entirely avoided, and the official process requires no apparatus but such as either is at hand in the pharmacy or can be easily obtained by a pharmacist operating upon the small scale.

4. The final thorough trituration of the dry powder reduces the soluble and active constituents of the drug to a pulverulent condition, the diluent is soluble, and the fine state of division of abstracts is the most favorable condition that a powder can possess to secure efficient medication. (*Remington's Practice of Pharmacy*, p. 427.)

* This process was substantially adopted in the German Pharmacopœia (1882). The old process of using dextrin as a diluent was found very objectionable, principally on account of the tendency of the extracts to reabsorb moisture.

extracts as require it, 10 per cent. of glycerin being added to the liquid extract before evaporation to a pilular consistence. By its unchangeable liquid character, glycerin keeps the extract soft, so that it can be readily made into pills, and it also exercises a favorable influence through its chemical properties. It is preferable to add a definite weight of the glycerin to the percolate. If it were added to the menstruum, owing to the variation in the yield of extracts from plants, some would be too soft, and at another time, in the case of a large yield of extract, the quantity of glycerin would be insignificant.

Extracts from recent plants should be prepared at the season when the plant is medicinally most active; and a good rule is to prepare them once a year.*

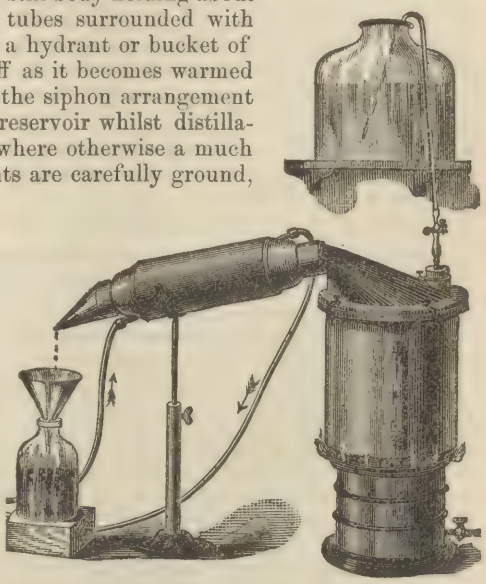
EXTRACTA FLUIDA. Fluid Extracts.

(ĘX-TRĂC'TĄ FLŪ'Į-DĄ.)

Extracta Liquida, *Br.;* Extraits liquides, *Fr.;* Flüssige Extrakte, *G.*

These were first introduced into the U. S. Pharmacopœia of 1850 as a distinct class of preparations; the fluid extract of sarsaparilla being the only one previously directed, either in our own official code or by the British Colleges. Since then they have increased so rapidly in favor that at the present time eighty-eight are official, and in addition large quantities of non-official fluid extracts are annually produced. They are now perhaps the most important class of liquid preparations in use. Their distinctive character is the concentration of the active ingredients of medicinal substances into a small bulk, in the liquid form, a cubic centimeter or fluigramme of any one of them now representing a gramme of the crude drug. Independently of the greater convenience of administration, the advantage of this class of preparations is that, the evaporation not being carried so far as in the ordinary extracts, the active principles are less liable to be injured by heat. Formerly the main difficulty in relation to them was the liability of substances in the liquid state to undergo spontaneous decomposition. In the Pharmacopœia of 1850 this was counteracted by means of sugar and of alcohol, but in 1865 (*A. J. P.*, 1865, p. 50) Mr. Alfred B. Taylor proposed the use of glycerin, and in the revision of the Pharmacopœia for 1870 his suggestion was adopted. Glycerin, while it exerts a powerful preservative influence, possesses the very valuable property of dissolving matters which were deposited by some of the fluid extracts when made with sugar, as in the old official recipes. Consequently these fluid extracts were much clearer and more elegant preparations than were the old ones. Subsequent experience with these fluid extracts showed that the use of glycerin should be circumscribed, and that it had been employed too freely in the formulas of the fluid extracts of the U. S. P. 1870. The solvent powers of glycerin are so great that the fluid extracts were frequently loaded with many inert principles, which it dissolved, giving them a dense, rich appearance, without increasing their activity. As the primary object of fluid extracts is concentration, suitable menstrua should in each case be selected with the single object of dissolving and retaining permanently the active constituents of the drug.

The present fluid extracts are of the same strength as those formerly official, and the formulas are based upon the theory that from a given weight of drug an amount of fluid extract shall be made equal in measure to the bulk of the same weight of distilled water; in other words, upon the relation of gramme to cubic centimetre.† Although the metric system is admirable in practice, some may prefer to use ordinary weights and measures; in such cases, to make 20 *fluidounces* of a fluid extract 19 *troyounces* of drug will be required, whilst if avoirdupois weight is preferred, the most convenient relation to recollect will be that 50 *avoirdupois ounces* are



* M. Lepage, of Gisors, gives the following method of testing the quality of the narcotic extracts and determining whether they contain any of the alkaloids to which they owe their efficiency. Take a gramme (15·5 gr.) of the extract, dissolve it in twice its weight of distilled water, introduce the solution into a test-tube, and add from 25 to 30 centigrammes (4 or 5 gr.) of powdered potassium bicarbonate. When effervescence has ceased, add to the mixture 5 or 6 times its bulk of pure ether, cork the tube, and shake briskly three times in 2 or 3 minutes. Then let the mixture rest; and when the ether has become transparent, decant, and allow it to evaporate spontaneously. Dissolve the residue in 6 or 8 grammes (f℥iss to f℥ij) of water acidulated with a drop or two of hydrochloric acid. If the extract be good, the solution will be rendered very turbid by a few drops of a solution of the double iodide of mercury and potassium, and will give a flocculent precipitate with solution of tannic acid. (*Journ. de Pharm.*, Mai, 1863, p. 362.) The test is applicable to the extracts of aconite, belladonna, hyoscyamus, and conium.

† The following table shows the relation of the crude drug to the fluid extract when made by the process of the U. S. P. 1890 and when made by that of the U. S. P. 1870:

Weight of Drug.	*Measure of Fluid Extract.*	
	Pharm. 1890.	Pharm. 1870.
100 grammes of drug make	100 C.c.	94·9 C.c.
100 troyounces of drug make	105·3 fluidounces.	100 fluidounces.
100 avoirdupois ounces of drug make	96 fluidounces.	91·1 fluidounces.

required to make 48 *fluidounces*, or *three pints*, of a fluid extract. It has been repeatedly proposed to make 50 *per cent. tinctures* or half-strength fluid extracts, the main object being to secure more representative preparations when made on the small scale. Experiments by Profs. Sayre, Gregory Patch, and others prove that half-strength fluid extracts possess no advantages over those of official strength. (*Drug. Circ.*, 1897, 119, 147.) The general formula for the preparation of fluid extracts does not differ materially from that formerly official; the length of time required for maceration has been judiciously reduced, whilst the quantity reserved has been generally slightly increased, although the formulas are not uniform in this respect. The fact cannot escape observation that there has been a close study of the solubilities, physical properties, and individuality of each drug, whilst uniformity among the formulas has not been sought for, so much as the best method of producing the fluid extract. The general formula may be expressed as follows. 1000 Gm. of the powdered drug are moistened with a certain quantity of menstruum, packed in a suitable percolator, and enough menstruum added to saturate the powder and leave a stratum above it; the lower orifice of the percolator is closed when the liquid begins to drop, and the percolator is closely covered to prevent evaporation and permit maceration for a specified time; additional menstruum is poured on and percolation continued until the drug is exhausted. Usually from seven- to nine-tenths of the first portion of the percolate are reserved, and the remainder evaporated to a soft extract; this is to be dissolved in the reserved portion, and enough menstruum added to make the fluid extract measure 1000 C.c. The precipitation experienced heretofore when the evaporated weak percolate was added to the reserved portion is considerably diminished by causing the former to be evaporated to a soft extract. This precipitation, formerly noticed more particularly in alcoholic fluid extracts, was due to the greater volatility of the alcohol in the weak percolates, which, when evaporated, left the residue to a great extent aqueous; when this was added to the strongly alcoholic reserved portion, a precipitation of resinous and frequently active matter took place, which necessitated the storing of the fluid extract until precipitation ceased, and subsequent filtration. This is almost altogether avoided by evaporating to a soft extract, and the loss of activity through precipitation is thus greatly diminished.

A useful distillatory apparatus has been contrived by Prof. Jos. P. Remington for recovering alcohol from weak percolates, and for general pharmaceutical uses. The still shown in the cut is the new form. It is made of tinned copper, the still body holding about three gallons; the condenser has seven straight tubes surrounded with the cold water introduced by a rubber tube from a hydrant or bucket of water placed higher than the still, and carried off as it becomes warmed by another tube as indicated by the arrows. By the siphon arrangement shown in the cut, the still can be fed from a reservoir whilst distillation is in progress, thus using a three-gallon still where otherwise a much larger one would have been necessary. The joints are carefully ground, and troublesome lutes and water-joints are entirely superseded. The condenser, having straight tubes instead of a spiral one, is easily cleaned, and is powerful enough to condense a gallon of alcohol in thirty minutes. The still may be set into a kettle partly filled with water and thus used as a water-bath, or a shallow tinned-copper dish with flat rim, which accompanies the still, may be placed between the two brass ring bands and clamped securely. (*A. J. P.*, May, 1879.)

For valuable papers on percolation and fluid extracts, by Prof. Procter, Dr. Squibb, Alonzo Robbins, and others, see *Proc. A. P. A.*, 1859, p. 265; 1863, p. 222; *A. J. P.*, 1878, pp. 209, 329; 1873, pp. 85, 189.

Several methods have been suggested for preparing fluid extracts more economically. The most important is the plan of repercolation, as proposed by Dr. E. R. Squibb, for this class of preparations as well as the dry extracts.

Repercolation. In consequence of the existing high price of alcohol, it is important to adopt some plan by which, while the ends aimed at are attained, the consumption of the menstruum used in percolation may be diminished. This object has been accomplished, to a

considerable extent, by Dr. E. R. Squibb, of Brooklyn, N. Y., by a modification of the process of percolation to which he has given the name at the head of the present paragraph. As defined by the author, repercolation consists in the successive application of the same percolating menstruum to fresh portions of the substance to be percolated. The result is that the same menstruum, acting repeatedly on unexhausted portions of the substance, becomes concentrated to the greatest possible extent, so that much of the menstruum is saved, while subsequent evaporation is avoided, which is itself an object of great importance in the preparation of extracts. It is obvious that repercolation is not applicable to the preparation of infusions, decoctions, tinctures, etc., in which the object in general is less a high degree of concentration than precision in the strength of the preparation, and consequently in the dose. It is to the extracts and fluid extracts that the process is peculiarly adapted, and there now remains no doubt whatever of the great value of the improvement. One of its disadvantages is that the substance treated is less completely exhausted than when the proceeding is inverted, and fresh portions of menstruum are made to act on the same material until the latter is deprived of all its soluble matter. But the loss in this way is trifling, compared with the gain when a menstruum as high-priced as alcohol is at the present time is employed. Another practical disadvantage is the inconvenience of keeping the weak percolates, as these have to be labelled, numbered, and stored away for use until the same operation is repeated. In deciding when to adopt it, the operator will of course be influenced by the relative value of the drug and the menstruum. In order to secure the most favorable results in repercolation, certain methods of proceeding are advisable in various steps of the process, differing with the character of the substance to be acted on; and these can be determined only by a careful study, confirmed by repeated experiment. Dr. Squibb uses repercolation exclusively on the large scale in the manufacture of extracts and fluid extracts, and has applied it especially to the preparation of fluid extract of cinchona; and since his first paper, which was reproduced in the 14th revision of the U. S. Dispensatory, p. 1164, he has introduced several improvements, which are intended to make the process useful to the apothecary in his every-day work. By presenting in a note below an abstract of his plan of proceeding in this case, we can impress on the mind of the pharmaceutical student the lessons applicable to the case more forcibly than could be done by a general description.*

The plan of Mr. N. Spencer Thomas consists in exposing the substance to be acted on to successive expressions, by means of a press, with the menstruum divided into different portions, so that fresh portions of liquid are brought to act on the same solid body in different stages of exhaustion, and then mixing the expressed liquids. The due proportion between the weight of the medicine and the bulk of the ultimate fluid extract is secured by regulating the measure of the last-added portion of menstruum, which, in the process as described by Mr. Thomas, is the third. Whatever may be the advantages of this method,—and it is not without its recommendations,—it is liable to the objections of loss of alcohol through exposure during expression, and of being patented. (*A. J. P.*, 1866.) Another method of limiting the quantity of alcohol used has been proposed by Mr. S. P. Duffield, of Detroit. It consists in macer-

* *Dr. Squibb's Process for Extract of Cinchona by Repercolation:* "Take of Yellow Cinchona, in powder No. 50, 32 parts; Stronger Alcohol, sp. gr. ·819, 2 parts; Glycerin, sp. gr. 1·250, 1 part; Water, 2 parts, or a sufficient quantity of menstruum. Weigh the Stronger Alcohol, Glycerin, and Water in succession, in any convenient quantity at a time, into a tared bottle, and mix them thoroughly for a menstruum.

"Moisten 8 parts of the Cinchona with eight parts of the menstruum, by thoroughly mixing them, and allow the mixture to stand 8 hours in a closely-covered vessel. Then pass the moist powder through a No. 8 sieve, and pack it firmly in a percolator. Pour menstruum on top until the mass is filled with liquid and a stratum remains on top unabsorbed; cover the percolator closely and macerate for 48 hours. Then arrange the percolator for an automatic supply of menstruum, and start the percolation at such a rate as to give 1 part of percolate in about 4 hours. Reserve the first 6 parts of percolate, and continue the percolation until the Cinchona is exhausted, separating the percolate received after the reserved portion into fractions of about 8 parts each. Moisten a second portion of 8 parts of the Cinchona with 8 parts of the weak percolate,—the first portion that was obtained next after the reserved percolate,—and allow the moist powder to stand for 8 hours in a vessel closely covered. Then pack it moderately in a percolator, and supply the percolator automatically with the remaining fractions of the weak percolate in the order in which they were received, and finally with fresh menstruum until the Cinchona is exhausted. Percolate in the same manner and at the same rate as with the first portion of Cinchona, and, reserving 8 parts of the first percolate, separate the weaker percolate into fractions of about 8 parts each. Percolate the third and fourth portions of 8 parts each of the Cinchona in the same way as the second portion. Finally mix the four reserved percolates together to make 30 parts of finished fluid extract; and having corked, labelled, and numbered the bottles containing the fractions of weak percolate, set them away until the process for Cinchona is to be resumed.

"When this fluid extract is to be again made, repeat the process as with the second portion, and reserve 8 parts of the first percolate as finished fluid extract from each 8 parts of Cinchona from that time forward so long as the fractions of weak percolate are carried forward with which to commence each operation." See also Dr. Squibb's percolator, 16th edition U. S. D., p. 600.

ating, for from six to ten days, the medicine to be acted on, previously deprived, by means of a vacuum apparatus, of all the air, and of all readily volatilizable matter contained in its pores, with a certain volume of the menstruum, which is forced through a tube into the vacuum-pan by atmospheric pressure, and thus brought into the most intimate contact with all parts of the powder. The process is completed by submitting the mass thus impregnated to hydraulic pressure, and, after allowing the liquid to settle in glass carboys, drawing off the clear liquid into bottles. (See also Parke, Davis & Co.'s method, with illustrations, *Remington's Practice of Pharmacy*, pp. 364, 365.) It is obviously inapplicable to substances whose virtues depend in any considerable degree upon readily volatilizable constituents. Mr. Campbell (*A. J. P.*, xlii. 17) has proposed a method for doing away with the use of heat, which, however, although in some cases it may do well, cannot be relied upon for the complete exhaustion of all drugs. In carrying it out, mix with sixteen troyounces of the powder four to six fluidounces of the menstruum (usually alcohol), and pack it in a glass funnel moderately but uniformly tightly, a piece of sponge having previously been put in the beak of the funnel; then cover the surface of the powder with a disk of paper, and pour on twelve fluidounces of menstruum. When the sponge becomes saturated, cork tightly the beak of the funnel, and set the whole aside for four days, at the end of which time the percolation may be allowed to proceed. Mr. James W. Mill has called attention to the advantage of separating the powder into fine and coarse parts by means of sieves and packing the finer powder at the bottom.

H. Biroth (*Pharmacist*, April, 1877) proposes the method which he terms "*insuccation*," for making non-alcoholic fluid extracts: the advantages claimed for it are simplicity and economy. Colaz prepares fluid extracts from fresh plants by bruising and crushing them, and placing the mass in a dialyzer suspended in 90 per cent. alcohol; when the dialysis is completed, the liquid is evaporated to free it from alcohol, the remaining aqueous liquid retaining the active constituents in the proportions in which they are found in the plant. (*Pharm. Post*, xxix. 271.) Haussmann (*A. J. P.*, 1895, 291), after examining a large number of commercial fluid extracts, records his results in tabular form, and considers that there is great variation in the quality, due to deviation from pharmacopœial processes.

Prof. J. U. Lloyd proposes to recover the alcohol which remains absorbed by the residue after percolation by mixing the wet residues with an equal bulk or less of dry sawdust, and then percolating this with water. (*A. J. P.*, June, 1877.) Wm. M. Thomson, of Philadelphia, devised a very complete method of preparing fluid extracts on a large scale; the principles of his process are maceration and percolation *in vacuo*, and although the principles which have been applied have been long known, and similar apparatus used by Duffield and others, there are many useful practical points which merit a notice in detail. The percolators are egg-shaped, and made of tinned copper; they are capable of being tightly covered, and communicate by means of stopcocks above and below, and iron and stout rubber tubing, with a very efficient double-acting air-pump. The moistened powder is packed tightly in the percolator, and the cover securely bolted on. The stopcock in the cover is now opened, which communicates with the air-pump and a partial vacuum created in the space above the moistened drug; the stopcock is now closed and another stopcock in the cover opened, which communicates by a tube with the reservoir containing the menstruum. The menstruum, of course, quickly penetrates the powder, taking the place of the interstitial air, and when the powder is saturated it is permitted to macerate *in vacuo* a sufficient length of time. To start percolation, a receiver is connected with the beak of the percolator, and, the air being exhausted from it, the percolate at once makes its appearance. When the flow slackens, if desired, air may be forced by the pump in the space above the powder, and the receiver again exhausted below. In this way, it can be seen, entire control of these powerful physical forces may be secured. The advantages are very apparent in preventing the loss of volatile principles and alcohol, whilst protecting from chemical change caused by exposure to the air. It is quite possible to make many official fluid extracts without recourse to subsequent evaporation of weak percolate. For a cut of this apparatus, see *A. J. P.*, 1882.

EXTRACTUM ACONITI. U. S. Extract of Aconite.

(EX-TRĂC'TUM ĂC-Q-NĪ'TĪ.)

Extract of Aconite Root; Extrait de Racine d'Aconit, *Fr.;* **Eisenhutknollen-Extrakt,** *G.*

"Aconite, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the

percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *three thousand cubic centimeters* [or 100 fluidounces] of tincture are obtained, or the Aconite is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, evaporate the remainder in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], add the reserved portion, and evaporate, at or below the above-mentioned temperature, until an extract of a pilular consistence remains." *U. S.*

The Br. Ph. (1898) no longer recognizes extract of aconite. (See *U. S. D.*, 17th ed., 533.) The extract from the fresh leaves of aconite was abandoned in the U. S. Pharmacopœia in 1870 in favor of one made by means of alcohol from the dried plant, probably because the plant was not generally cultivated in this country. But the *present preparation is very much stronger* than either, aconite root having been substituted for the leaves, which are no longer official, and alcohol for diluted alcohol as a menstruum. It is greatly to be regretted that the title of this Extract is not Extractum Aconiti Radicis; there will be likely to be three extracts of Aconite in use, of varying strengths,—*i.e.*, the present official alcoholic extract made from the root, the former hydro-alcoholic extract made from the leaves, and the English extract made from the fresh leaves. Great care should be taken to call as much attention to the alteration as possible. The use of tartaric acid in the menstruum for U. S. P. 1880 was in accordance with the views of Duquesnel and C. R. Alder Wright. It has been shown, however, that the acid was of no practical advantage, and it is no longer employed. The exhaustion of the aconite in the U. S. process is indicated by the absence of its peculiar taste in the liquid which passes. To save the alcohol at the low temperature at which the evaporation is directed, would require the aid of a vacuum apparatus. The attempt to save the alcohol by ordinary distillation would imply an elevation of the heat above that officially ordered, and thus endanger the decomposition of the active principle of the aconite; and views of economy should never be allowed to interfere with the efficiency of medicines.

If made from recently dried leaves, which have not yet been impaired by time, the extract official in 1870 was a good preparation of aconite; and it was believed to be more powerful, and to keep better, than the inspissated juice. According to Prof. Schroff, of Vienna, it had four times the strength of that preparation. The dose is half a grain or a grain (0·03 to 0·065 Gm.), to be gradually increased if necessary. The alcoholic extract of the U. S. P. 1890 is stronger, and may be given in the dose of one-sixth or one-quarter of a grain (0·01 to 0·016 Gm.), to be gradually increased until its effects are experienced; and it would be well to specify on the prescription U. S. P. 1890 when that preparation is desired.

When properly prepared, the Br. Ph. 1885 extract has a greenish-brown color, with a disagreeable narcotic odor and the acrid taste of the plant. It may be given in the dose of one or two grains (0·065 to 0·13 Gm.), night and morning, to be gradually increased till the system is affected. Twenty grains (1·3 Gm.) or more have been given in the course of a day.

EXTRACTUM ACONITI FLUIDUM. U. S. Fluid Extract of Aconite.

(ĘX-TRĂC'TUM ĂC-Q-NĪ'TĪ FLŪ'Ị-DŬM.)

Fluid Extract of Aconite Root; Extrait liquide de Racine d'Aconit, *Fr.*; Flüssiges Eisenhutknollen-Extrakt, *G.*

"Aconite, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Aconite is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This preparation of aconite root will be found useful as a basis for making the other prepa-

rations of Aconite,—the plaster, extract, tincture, or liniment. The fluid extract is of a bright deep reddish-brown color; it may be given internally in doses of one-half to one minim (0·03 to 0·06 C.c.), but on account of its very powerful character should always be used with caution, beginning with the smallest dose. It will doubtless be frequently employed as an addition to liniments for obtaining the peculiar effects of aconite.

EXTRACTUM ALOES. U. S. Extract of Aloes.

(ĘX-TRĂC'TUM ĂL'Ǫ-ĒS.)

Extrait d'Aloès, *Fr.;* Aloe-Extrakt, *G.*

"Socotrine Aloes, *one hundred grammes* [or 3 ounces av., 230 grains]; Boiling Distilled Water, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Aloes with the Water in a suitable vessel, stirring constantly, until the particles of Aloes are thoroughly disintegrated, and let the mixture stand for twelve hours; then pour off the clear liquor, strain the residue, mix the liquids, and evaporate to dryness by means of a water- or steam-bath." *U. S.*

The object of this preparation is to afford an aloes purified from mechanical impurities. The process is based upon the British formulas for extract of Barbadoes aloes and Socotrine aloes, which are treated of in the two articles following this. With an official purified aloes, the necessity for this preparation is not obvious.* An extract made with cold distilled water was formerly official in the German Pharmacopœia, as was also the vitriolated extract, "*Extractum Aloes Acido Sulfurico Correctum*," made by suspending eight parts of extract of aloes in thirty-two parts of distilled water, adding drop by drop one part of pure sulphuric acid, and evaporating in a porcelain vessel to dryness. The dose is from two to ten grains (0·13–0·65 Gm.).

EXTRACTUM ALOES BARBADENSIS. Br. Extract of Barbados Aloes.

(ĘX-TRĂC'TUM ĂL'Ǫ-ĒS BĂR-BĄ-DĔN'SIS.)

Extrait d'Aloès de Barbade, *Fr.;* Barbadoes Aloe-Extrakt, *G.*

"Barbados Aloes, in small fragments, 1 *pound* (Imperial) or 1000 grammes; Distilled Water, boiling, 1 *gallon* (Imp. meas.) or 10 litres. Add the Barbados Aloes to the Distilled Water and stir well until they are thoroughly mixed; set the mixture aside for twenty-four hours; decant; strain; evaporate the strained liquid to dryness at a temperature not exceeding 140° F. (60° C.)." *Br.*

The revised direction, to evaporate at a temperature not exceeding 140° F. (60° C.), instead of "by a current of warm air," is an improvement. The dose of this extract is from two to six grains (0·13–0·4 Gm.). *Extract of Socotrine Aloes*, made by a similar process, was dropped at the last revision of the British Pharmacopœia.

EXTRACTUM ANTHEMIDIS. Br. Extract of Chamomile.

(ĘX-TRĂC'TUM ĄN-THĔM'Į-DĬS.)

Extrait de Camomille romaine, *Fr.;* Extractum Chamomillæ Romanæ; Römisch-Kamillen-Extrakt, *G.*

"Chamomile Flowers, 1 *pound* (Imperial) or 1000 grammes; Oil of Chamomile, 15 *minims* (Imp. meas.) or 2 cubic centimetres; Distilled Water, 1 *gallon* (Imp. meas.) or 10 litres. Boil the Chamomile Flowers with the Distilled Water until the volume is reduced to one-half; strain; press; filter; evaporate the filtrate to the consistence of a soft extract; add the Oil of Chamomile towards the end of the process." *Br.*

According to Mr. Brande, one cwt. of dried chamomile flowers affords upon an average 48 pounds of extract.

This extract has a deep brown color, with the bitter taste and aroma of chamomile. It much better represents the chamomile than did the old Edinburgh extract, which, being obtained by

* *Glycerate of Aloes. Glycerole of Aloes.* Under the latter name, M. Chausit brought to the notice of the profession a preparation consisting of an alcoholic extract of aloes dissolved in glycerin. Mr. Haselden prepared this by the following method. Macerating half an ounce of aloes in four fluidounces of alcohol until dissolved, he filtered the tincture through bibulous paper, evaporated it to the consistence of molasses, and, while it was still warm, added enough glycerin to make four fluidounces. Finding that the aloes was wholly dissolved, with the exception of a little impurity, he concluded that the spirit might very well be dispensed with, and the aloes used directly in the process. Accordingly he proposes to substitute the following method. Mix well in a mortar half an ounce of Socotrine aloes, in fine powder, and four fluidounces of glycerin; transfer the mixture to a bottle, and agitate occasionally for several days; if the aloes be not now dissolved, heat for fifteen minutes by a water-bath, and strain through linen to separate impurities. The resulting liquid is of a bright mahogany color, and of the consistence of glycerin. The preparation has been recommended as an external remedy in *lichen agrius* and the excoriations of *eczema*, applied by means of a camel's-hair brush. (*P. J. Tr.*, 1859, p. 322.) For the mode of preparing *a fluid extract of aloes* with the aid of glycerin, by Prof. Procter, see *Proc. A. P. A.*, 1863, p. 240.

decoction and inspissation, contained none of the volatile oil of the plant. In the present British process care is taken not only to avoid boiling, but also to supply any possible loss of oil during the cautious evaporation, by the addition of a small portion near the close of the process. The extract may be given for the same purpose as the flowers, but is most used as a vehicle for other tonics in the pilular form. The dose is from two to ten grains (0·13 to 0·65 Gm.). An extract may be prepared having the peculiar flavor as well as bitterness of chamomile, by macerating the flowers in water, and evaporating the infusion *in vacuo*.

EXTRACTUM APOCYNI FLUIDUM. U.S. Fluid Extract of Apocynum.

(ĘX-TRĂC'TUM Ą-PŌÇ'Y-NĪ FLŪ'Į-DŬM.)

"Apocynum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Alcohol to *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Water, until the Apocynum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract: it represents apocynum in a very satisfactory manner. The dose is five minims (0·3 C.c.); as an emetic, fifteen to twenty minims (0·9 to 1·25 C.c.).

EXTRACTUM ARNICÆ RADICIS. U.S. Extract of Arnica Root.

(ĘX-TRĂC'TUM ĂR'NĮ-ÇÆ RĄ-DĪ'CĪS.)

Extrait de Racine d'Arnique, *Fr.*; **Arnika-Extrakt**, *G.*

"Arnica Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for twenty-four hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Arnica Root is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate; evaporate the remainder to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], at a temperature not exceeding 50° C. (122° F.), mix the residue with the reserved portion, and evaporate, at or below the above-mentioned temperature, to a pilular consistence." *U. S.*

The extract does not differ from the extract formerly official: it very well represents the virtues of arnica, and is a convenient form for its administration. The dose is from three to five grains (0·20 to 0·33 Gm.). But the chief employment of the extract is in the preparation of the plaster. (See *Emplastrum Arnicæ*.)

EXTRACTUM ARNICÆ RADICIS FLUIDUM. U.S. Fluid Extract of Arnica Root.

(ĘX-TRĂC'TUM ĂR'NĮ-ÇÆ RĄ-DĪ'CĪS FLŪ'Į-DŬM.)

Extrait liquide de Racine d'Arnique, *Fr.*; **Flüssiges Arnicawurzel-Extrakt**, *G.*

"Arnica Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217

minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Arnica Root is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is of a clear, reddish-brown color, possessing little odor, and having an acrid taste. It well represents the virtues of the root, and will probably be used as a basis for preparing the extract when wanted for the plaster. The dose, if desired for internal administration, would be from five to ten minims (0·3–0·6 C.c.).

EXTRACTUM AROMATICUM FLUIDUM. U. S. Aromatic Fluid Extract.

(ĘX-TRĂC'TŲM ĂR-Ǫ-MĂT'Į-CŬM FLŪ'Į-DŬM.)

Extrait liquide aromatique, *Fr.*; Flüssiges Aromatisches Extrakt, *G.*

"Aromatic Powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Aromatic Powder is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a valuable fluid extract; it is an excellent aromatic in concentrated form, and will be found very useful not only as an addition to liquids when an aromatic is desired, but its concentrated form will permit its use in small quantities with dry powders, like pepsin, bismuth subnitrate, etc., when desired for administration. It will probably be rarely used alone. Dose, ten to twenty minims (0·6–1·25 C.c.), diluted with water, or dropped on sugar.

EXTRACTUM ASCLEPIADIS FLUIDUM. U. S. Fluid Extract of Asclepias.

(ĘX-TRĂC'TŲM ĄS-CLĒ-PĮ-Ā'DĬS FLŪ'Į-DŬM.)

"Asclepias, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Asclepias is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract; it has a deep brownish-red color. The dose is from twenty minims to a fluidrachm (1·25 to 3·75 C.c.).

EXTRACTUM ASPIDOSPERMATIS FLUIDUM. U. S. Fluid Extract of Aspidosperma.

(ĘX-TRĂC'TŲM ĂS-PĮ-DǪ-SPĔR'MĄ-TĬS FLŪ'Į-DŬM.)

"Aspidosperma, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each,

a sufficient quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for 48 hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, until the Aspidosperma is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This preparation, which has been largely used under the name of *fluid extract of quebracho*, well represents the drug. The dose is fifteen minims to a fluidrachm (0·9 to 3·75 C.c.).

EXTRACTUM AURANTII AMARI FLUIDUM. U. S. Fluid Extract of Bitter Orange Peel.

(ĘX-TRĂC'TUM ÂU-RĂN'TI-Ī Ą-MĀ'RĪ FLŪ'I-DŬM.)

Extrait liquide d'Écorce d'Oranges amères, *Fr.;* Flüssiges Pomeranzenschale-Extrakt, *G.*

" Bitter Orange Peel, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it moderately in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Orange Peel is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is another fluid extract which will be found useful as a tonic; the bitter orange peel having very little oil present in its dry condition, there is necessarily very little agreeable orange flavor to the fluid extract. Monroe Bond recommends a *Fluid Extract of Sweet Orange Peel*, made with a menstruum of seven parts of alcohol and one of glycerin. (*A. J. P.*, 1873, p. 482.) Dose, fifteen to thirty minims (0·9–1·9 C.c.).

EXTRACTUM BELLADONNÆ FOLIORUM ALCOHOLICUM. U. S. (Br.) Alcoholic Extract of Belladonna Leaves.

(ĘX-TRĂC'TUM BĔL-LĄ-DŌN'NÆ FŌ-LI-Ō'RŬM ĂL-CO-HŎL'I-CŬM.)

" An Extract containing one per cent. of the alkaloids of Belladonna Root." *Br.*

Extractum Belladonnæ Alcoholicum, *Br.;* also *U. S.*, 1880; Extrait de Belladone alcoolique, *Fr.;* Spirituöses Tollkirschen-Extrakt, *G.*

" Belladonna Leaves, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of Alcohol with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 fluidrachms] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until *three thousand cubic centimeters* [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Belladonna Leaves are exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207

minims] of the percolate, evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], mix the residue with the reserved portion, and evaporate at or below the above-mentioned temperature to a pilular consistence." *U. S.*

"Evaporate *one fluid ounce* (Imperial measure) or fifty cubic centimetres of Liquid Extract of Belladonna, in a counterpoised basin, on a water-bath, to the consistence of a moderately firm extract; weigh. The difference between the weight of the residue and *three-quarters of an ounce* (Imp.) or thirty-seven and a half grammes gives the weight of Milk Sugar to be used as a diluent for each *fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Liquid Extract.

"Evaporate *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of Liquid Extract of Belladonna to the consistence of a thin syrup; add to it the required quantity of Milk Sugar determined from the data obtained from the foregoing experiment; continue the evaporation until the extract weighs *fifteen ounces* (Imp.) or seven hundred and fifty grammes. This Alcoholic Extract of Belladonna contains one-third the proportion of alkaloids present in average samples of the Alcoholic Extract of Belladonna of the British Pharmacopœia of 1885." *Br.*

The alcoholic extracts of belladonna of the U. S. P. 1880 and 1890 were made from the leaves, in deference to a prejudice which seems to have a strong following. The British Pharmacopœia introduced in the 1885 revision for the first time an alcoholic extract of belladonna, but it differed from the U. S. extract in being made from the root instead of the leaves. (See *Extractum Belladonnæ Viride*, p. 545.) The British alcoholic (root) extract (1898) is 66 per cent. weaker than the Br. Pharm. 1885 extract; it now contains 1 per cent. of the alkaloids of belladonna root, and is only one-fourth stronger than the liquid extract. Whilst the advantage of establishing a definite relation between the two is apparent, in our opinion it would have been better not to have reduced the strength so enormously as 66 per cent.; but the extract could have been made to contain 1½ per cent. of alkaloids, and, besides, this would have conveniently made the extract just double the strength of the liquid extract. The reduction in strength was no doubt made for the purpose of avoiding accidents in dispensing due to having two official Extracts of Belladonna. The dose of both British extracts is now the same. (*P. J. Tr.*, 1895, 795.) The absence of chlorophyll in an extract made from the root would cause ointments, cerates, plasters, etc., made from it to be deficient in the characteristic green color so much prized, but there can be no question of the greater uniformity in strength of the root.* For a method of assaying Extract of Belladonna, by Beckurts, see *Pharm. Era*, 1887, 447.

The formula for this extract does not differ essentially from that official in the former revision: it is a good preparation, and is official in the French Codex. It is much used externally. Thus, in *rigidity* of the *os uteri*, it is applied at intervals to the neck of the uterus, mixed with simple ointment in the proportion of one drachm to an ounce; but care must be taken not to affect the system too powerfully; and the preparation, therefore, should be used in a small quantity at first. In *irritability* of the *bladder*, *chordee*, *spasm* of the *urethra* or of the *rectum*, it may either be rubbed in the form of ointment upon the perineum, or be used in the form

* *Standard Extract of Belladonna.* This preparation has been proposed by Profs. Dunston and Ransom as a type of a class of standardized solid extracts having a definite alkaloidal strength: whilst resembling an extract, it has the advantage over it of being based upon a certain percentage of alkaloid instead of representing a given amount of a variable drug. "Take of belladonna root, in No. 20 powder, 1 pound; rectified spirit, 48 fluidounces; distilled water, 12 fluidounces. Mix the spirit with the water. Macerate the belladonna in 2 pints of this mixture for forty-eight hours, agitating occasionally; then transfer to a percolator, and when the fluid ceases to pass, continue the percolation with the remainder of the diluted spirit. Afterwards subject the contents of the percolator to pressure, filter the product, mix the liquids, and measure the exact volume of the mixture (a). Estimate the alkaloidal nature of this solution by the following method. Evaporate 50 C.c. of the liquid over a water-bath with a gentle heat until all the alcohol is dispelled. Dissolve the extract thus obtained in about 5 C.c. of warm distilled water acidulated with a few drops of diluted hydrochloric acid; filter, if necessary, through a small fragment of cotton-wool; pour into a stoppered glass separator, and add ammonia until the solution is distinctly alkaline. Agitate for a few minutes with 5 C.c. of chloroform, separate, and again wash the aqueous liquid with 3 C.c. of chloroform. Agitate the mixed chloroformic solutions with 5 C.c. of diluted hydrochloric acid, separate, again wash with 3 C.c. of the diluted acid, mix the acid solutions, render alkaline with ammonia, and agitate with 5 C.c. of chloroform. After separation, wash the alkaline solution with 3 C.c. of chloroform, mix the chloroformic solutions, evaporate in a dish of known weight, and dry the residue, which should be nearly colorless at a temperature of 200° F. (93° C.). The weight of the residue thus obtained multiplied by 2 will give the parts by weight of the alkaloids in 100 fluid parts of the liquid. The exact volume of the liquid being known, and the strength having been thus ascertained, the total amount of alkaloid present therein can be calculated. Evaporate to dryness over a water-bath, and add sufficient sugar of milk to make the mixed product exactly fifty times the weight of the total alkaloid found to have been present in the liquid (a), allowing for that quantity which was used for the estimation. Mix intimately, powder as quickly as possible in a dry atmosphere, and transfer at once to a well-stoppered bottle. This extract will contain 2 per cent. of total alkaloid." (*P. J. Tr.*, 1887, p. 844.)

of suppository; but care is requisite not to introduce it too freely into the bowel. It is sometimes smeared upon the bougie, mixed with oil, in the treatment of stricture of the urethra. In the form of ointment it has been beneficially employed in *phimosis* and *paraphimosis*, and in that of plaster or ointment, in local *neuralgic* or *rheumatic pains*. (See *Emplastrum Belladonnæ*.) Internal dose, from one-sixth to one-third of a grain (0·010 to 0·021 Gm.).

EXTRACTUM BELLADONNÆ RADICIS FLUIDUM. U. S. (Br.) Fluid Extract of Belladonna Root. [Extractum Belladonnæ Fluidum, Pharm. 1880.]

(ĘX-TRĂC'TŲM BĚL-LĄ-DŎN'NÆ RĄ-DĪ'CĬS FLŪ'Į-DŬM.)

"A Liquid Extract containing ¾ grain of the alkaloids of Belladonna Root in 110 minims (0·75 gramme in 100 cubic centimetres)." *Br.*

Extractum Belladonnæ Liquidum, *Br.*, Liquid Extract of Belladonna; Extrait liquide de Racine de Belladone, *Fr.*; **Flüssiges Tollkirschenwurzel-Extrakt,** *G.*

"Belladonna Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Belladonna Root is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Moisten *eight ounces* (Imperial) or three hundred and twenty grammes of Belladonna Root, in No. 20 powder, with *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of a mixture of seven volumes of Alcohol (90 per cent.) and one volume of Distilled Water; set aside for six hours; pack firmly in a percolator; pour over the powder *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of the same alcoholic menstruum; when the liquid begins to drop, close the lower orifice of the percolator; set aside for twenty-four hours; percolate slowly, adding more of the menstruum as required; collect the percolate in small portions. Moisten a second quantity of *eight ounces* (Imp.) or three hundred and twenty grammes of Belladonna Root, in No. 20 powder, with the first *six fluid ounces* (Imp. meas.) or two hundred and forty cubic centimetres of percolate; proceed to extract this portion of the Belladonna Root in the manner directed for the first portion, but use as the menstruum the liquid collected from the first percolator. This method of repercolation is to be carried out through two more quantities each of *eight ounces* (Imp.) or three hundred and twenty grammes of Belladonna Root, the third portion being extracted with the liquid from the second percolator, and the fourth portion with the liquid from the third percolator. Collect *twelve and a half fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the strong percolate from the fourth percolator.

"Determine the proportion of alkaloids in the resulting strong percolate by the following analytical process.

"Introduce 10 cubic centimetres into a separator, add 10 cubic centimetres of *chloroform*, 50 cubic centimetres of *water*, and a decided excess of *solution of ammonia*; agitate; set aside; separate the chloroformic solution. Twice repeat the agitation with *chloroform* and the separation. Shake the mixed chloroformic solutions with 5 cubic centimetres of *diluted sulphuric acid*, mixed with twice its volume of warm *water*; separate the chloroformic liquid and repeat the agitation with acidulated *water*. Wash the mixed acid liquids with 3 cubic centimetres of *chloroform*; then agitate with 10 cubic centimetres of *chloroform* and an excess of *solution of ammonia*. Separate the chloroformic solution; twice repeat the agitation with *chloroform* and the separation; wash the mixed chloroformic solutions with 5 cubic centimetres of *water* containing one drop of *solution of ammonia*; draw off the chloroformic layer into a counterpoised dish; evaporate on a water-bath; dry the residue below 212° F. (100° C.); weigh. Dissolve the residue in 10 cubic centimetres of a decinormal solution of hydrochloric acid (3·619 grammes of the acid, HCl, per litre) and add centinormal solution of soda (0·3976

gramme of sodium hydroxide, NaOH, per litre) until the liquid is neutral, using Tincture of Cochineal as an indicator. Deduct the measure of soda solution thus required, from 100 cubic centimetres, and multiply the remainder by 0·00287; the product will be the weight in grammes of alkaloids present in the quantity of the percolate operated upon.

"From this weight calculate the amount of alkaloids in the bulk of strong percolate, and add to the latter sufficient of the alcoholic menstruum to produce Liquid Extract of Belladonna containing 0·75 gramme of alkaloids in 100 cubic centimetres, or ¾ grain in 110 minims." *Br.*

The British liquid extract represents several radical improvements in British pharmacy,—*i.e.*, the use of repercolation with absence of heat in the process, and standardization, thus making the end product bear a definite relation towards the quantity of active constituents found in the root (0·75 per cent.). It is based upon the formula proposed by R. A. Cripps. (*P. J. Tr.*, 1895, 795.) The fluid extract of the root is a good preparation, of reddish-brown color, very different in appearance from the deep-green fluid extract of the leaves which is often seen in the market. Dose, from one to two minims (0·06–0·12 C.c.).

EXTRACTUM BELLADONNÆ VIRIDE. Br. Green Extract of Belladonna.

(ĘX-TRĂC'TŲM BĔL-LĄ-DŎN'NÆ VĪR'Į-DĒ.)

"Bruise the fresh leaves and young branches of Atropa Belladonna, Linn., in a mortar; press out the juice and heat it to 130° F. (54·4° C.); separate the green coloring matter by a calico filter; heat the strained liquid to 200° F. (93·3° C.); filter. Evaporate the filtrate on a water-bath to the consistence of a thin syrup; add to it the green coloring matter previously separated and passed through a hair sieve, stir the whole together, and evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of a soft extract." *Br.* This extract is identical with the Br. Pharm. 1885 extract of belladonna leaves made from the recent plant. The dose is from one-quarter to one grain (0·016 to 0·06 Gm.).

EXTRACTUM BUCHU FLUIDUM. U. S. Fluid Extract of Buchu.

(ĘX-TRĂC'TŲM BŪ'ØHŪ FLŪ'Į-DŬM—bū'kū.)

Extrait liquide de Bucco, *Fr.;* **Flüssiges Bucco-Extrakt,** *G.*

"Buchu, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Buchu is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The old menstruum (alcohol) for this fluid extract has been restored, experience having shown that with the weaker alcohol used in the U. S. P. 1880 formula it was impossible to percolate satisfactorily some samples of buchu leaves, the quantity of water present being sufficient to cause swelling to such an extent as to clog and entirely prevent percolation; with alcohol as a menstruum this cannot occur.

In consequence of the peculiar structure of the leaves, it is somewhat difficult to powder them in a mortar, and it will be convenient to resort to a mill for the purpose. As the most active ingredient of buchu is volatile, the direction in the formula to set aside the first portion of tincture obtained, which is a highly concentrated solution, is peculiarly important; for, if it were subjected to evaporation, much of the volatile oil would necessarily escape. The tincture subsequently obtained probably contains a large proportion of the fixed ingredients of the leaves, and will, therefore, allow of concentration without material loss.

This fluid extract is clear, greenish black, and possessed in a high degree of the sensible properties of the leaves. It acquires the odor of mint when long kept, showing that some change takes place in its volatile oil. This fluid extract affords the best means at our command for the exhibition of buchu. It is often combined with Liquor Potassæ with excellent results. Dose, from thirty minims to a fluidrachm (1·9–3·8 C.c.), three to five times a day.

EXTRACTUM CALAMI FLUIDUM. U. S. Fluid Extract of Calamus.

(ĘX-TRĂC'TUM CĂL'Ą-MĪ FLŪ'Į-DŬM.)

Extrait liquide d'Acore vrai, *Fr.;* Flüssiges Kalmuswurzel-Extrakt, *G.*

"Calamus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Calamus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which has been introduced with the view of bringing into use an excellent indigenous aromatic stimulant. It will probably be most frequently used in combination with tonics in dyspepsia and gastric disorders to relieve *flatulence*, etc. Dose, from five to fifteen minims (0·3–0·9 C.c.).

EXTRACTUM CALUMBÆ FLUIDUM. U. S. Fluid Extract of Calumba.

(ĘX-TRĂC'TUM CĄ-LŬM'BÆ FLŪ'Į-DŬM.)

Extrait liquide de Colombo, *Fr.;* Flüssiges Kolombo-Extrakt, *G.*

"Calumba, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Calumba is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The formula for fluid extract of calumba of the U. S. P. 1870 was faulty, in directing the root to be in fine powder: the large quantity of mucilage present swelled under the influence of the menstruum, and frequently prevented the passage of the percolate; indeed, the powder will probably still be found to give trouble, as there will be some difficulty in thoroughly exhausting it; it should be slowly percolated. This extract is a dark-brown liquid, of an intense and purely bitter taste. The absence of tannin makes it a very desirable tonic, in combination with chalybeates. Dose, from fifteen to thirty minims (0·9–1·9 C.c.).

EXTRACTUM CANNABIS INDICÆ. U. S., Br. Extract of Indian Cannabis.

(ĘX-TRĂC'TUM CĂN'NĄ-BĪS ĬN'DĮ-ÇÆ.)

Extract of Indian Hemp; Extrait de Chanvre indien, *Fr.;* Indischer Hanf-Extrakt, *G.*

"Indian Cannabis, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Cannabis is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, in a porcelain capsule, on a water-bath, to a pilular consistence." *U. S.*

"Exhaust Indian Hemp, in coarse powder, with Alcohol (90 per cent.) by percolation; evaporate the percolate to the consistence of a soft Extract." *Br.*

It will be noticed that the English name of the drug has been changed in the U. S. Pharmacopœia to Indian Cannabis, to prevent its being mistaken for the root of *Apocynum Cannabinum*, which is also called Indian Hemp. Several mistakes have occurred through this unfortunate confusion of nomenclature.

Although there is some difference in the details of the two processes, the preparations of the U. S. and Br. Pharmacopœias are practically identical. Prof. Procter investigated the subject of the tests for the purified extract or resin, and came to the following conclusions. Its peculiar odor when moderately heated, its indifference to alkalies, and its solubility in alcohol, ether, chloroform, benzol, and oil of turpentine are characteristic though not entirely distinctive properties. The best test, he found, was nitric acid (sp. gr. 1·38), which acts slowly when cold, but with heat rapidly, evolving red fumes, and converting the resin into an orange-red resinoid substance which, when washed and dried, closely resembles gamboge in color. (*Proc. A. P. A.*, 1864.) Care should be observed in selecting the drug for making this extract, and old cannabis indica should be rejected. The limit of age in India is said to be three years. (*P. J. Tr.*, 1894, 246; *Rép. de Pharm.*, 1894, 257.) The preparation varies exceedingly in strength, so that it is wisest to begin with a small dose, one-quarter of a grain (0·016 Gm.), and rapidly increase the amount given until some effect is produced.

EXTRACTUM CANNABIS INDICÆ FLUIDUM. U. S. Fluid Extract of Indian Cannabis.

(ĘX-TRĂC'TUM CĂN'NA-BĬS ĬN'DI-ÇÆ FLŪ'I-DŬM.)

Extrait liquide de Chanvre Indien, *Fr.*; Flüssiges Indischer Hanf-Extrakt, *G.*

"Indian Cannabis, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Indian Cannabis is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, in a porcelain capsule, to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which has come into use because of its convenience, and probably on account of the impression that heat injures the activity of the drug, and that the extract owes its inactivity sometimes to the influence of heat. (See *Cannabis Indica* and the previous article.) The fluid extract is of a dark green color, having the characteristic odor of the drug. Dose, from one-half to one minim (0·03–0·06 C.c.).

EXTRACTUM CAPSICI FLUIDUM. U. S. Fluid Extract of Capsicum.

(ĘX-TRĂC'TUM CĂP'SI-CĪ FLŪ'I-DŬM.)

Extrait liquide de Capsique, *Fr.*; Flüssiges Spanischer Pfeffer-Extrakt, *G.*

"Capsicum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Capsicum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The necessity for an official fluid extract of capsicum is not apparent, as the oleoresin and tincture are preparations which are well known and established. It will probably be rarely necessary to administer it internally. Dose, from one-half to one minim (0·03–0·06 C.c.).

EXTRACTUM CASCARÆ SAGRADÆ. Br. Extract of Cascara Sagrada.

[Extractum Rhamni Purshiani.]

(ĘX-TRĂC'TUM CĂS'CĄ-RÆ SĄ-GRĀ'DÆ.)

"Moisten Cascara Sagrada, in No. 20 powder, with Distilled Water, and let it remain a few hours to soften and swell; then place it loosely in a percolator and percolate with more Distilled Water until it is exhausted. Evaporate on a water-bath to dryness." *Br.*

The selection of the title is not above criticism: the title of the bark is "Rhamni Purshiani Cortex," and the extract should be termed "Extractum Rhamni Purshiani," or, to be uniform, the title of the bark itself changed. The present British preparation (1898) is a dry extract. This preparation well represents the virtues of the bark, and furnishes a good means of administering this purgative in pilular form. Dose, from two to eight grains (0·13–0·52 Gm.).

EXTRACTUM CASCARÆ SAGRADÆ LIQUIDUM. Br. Liquid Extract of Cascara Sagrada. [Extractum Rhamni Purshiani Liquidum.]

(ĘX-TRĂC'TUM CĂS'CĄ-RÆ SĄ-GRĀ'DÆ LĬQ'UĮ-DŬM—lĭk'wę-dŭm.)

Extractum Rhamni Purshianæ Fluidum, *U. S.*

"Cascara Sagrada, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (90 per cent.) 4 *fl. ounces* (Imp. meas.) or 200 cubic centimetres; Distilled Water, *a sufficient quantity.* Moisten the Cascara Sagrada with *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the Distilled Water, and set the mixture aside for six hours; then place it loosely in a percolator and percolate with more of the Distilled Water until the powder is exhausted; evaporate the percolate to *twelve fluid ounces* (Imp. meas.) or six hundred cubic centimetres; add the Alcohol, previously mixed with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of Distilled Water or with sufficient to make up the volume of the mixed liquids to *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.* This process has been improved by the adoption of percolation in the Br. Ph. 1898 in place of evaporating decoctions, and preserving the residue with alcohol as directed by the Br. Ph. 1885. Dose, from one-half to two fluidrachms (1·9–7·5 C.c.).

EXTRACTUM CASTANEÆ FLUIDUM. U. S. Fluid Extract of Castanea.

(ĘX-TRĂC'TUM CĂS-TĀ'NĘ-Æ FLŪ'Į-DŬM.)

Extrait liquide de Feuilles de Châtaignier, *Fr.;* Flüssiges Kastanienblätter-Extrakt, *G.*

"Castanea, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Pour *five thousand cubic centimeters* [or 169 fluidounces, 33 minims] of boiling Water upon the powder, allow it to macerate for two hours, then express the liquid, transfer the residue to a percolator, and pour Water upon it until the powder is exhausted. Evaporate the united liquids, on a water-bath, to *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms], allow this to cool, and add *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol. When the insoluble matter has subsided, separate the clear liquid, filter the remainder, evaporate the united liquids to *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims], allow this to cool, add the Glycerin, and enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The object of the special process is to obtain and retain the mucilaginous principle, and it will be observed that the preparation is an aqueous fluid extract with only sufficient alcohol to preserve it. It is a thick reddish-brown liquid, having an astringent taste. Dose, from one to two fluidrachms (3·75–7·5 C.c.).

EXTRACTUM CHIMAPHILÆ FLUIDUM. U. S. Fluid Extract of Chimaphila.

(ĘX-TRĂC'TUM ØHĮ-MĂPH'Į-LÆ FLŪ'Į-DŬM.)

Extrait liquide de Pyrole ombellée, *Fr.;* Flüssiges Doldenblüthiges Harnkraut-Extrakt, *G.*

"Chimaphila, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces,

252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Chimaphila is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a rather thick, dark brownish-green fluid extract, and may be given in the dose of a fluidrachm (3·75 C.c.).

EXTRACTUM CHIRATÆ FLUIDUM. U. S. Fluid Extract of Chirata.

(ĘX-TRĂC'TŲM ÇHĮ-RĀ'TÆ FLŪ'Į-DŬM.)

Extrait liquide de Chirette, *Fr.;* **Flüssiges Chiretta-Extrakt,** *G.*

" Chirata, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Chirata is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a useful addition to the list of fluid extracts. The menstruum has been made more alcoholic to reduce precipitation, and the use of glycerin abandoned. This extract is a clear, reddish-brown liquid, of an intensely bitter taste. The dose is half a fluidrachm (1·9 C.c.).

EXTRACTUM CIMICIFUGÆ. U. S. Extract of Cimicifuga.

(ĘX-TRĂC'TŲM CĬM-Į-CĬF'Ų-ĢÆ.)

" Cimicifuga, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Cimicifuga is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

This is a new official extract; its introduction is due to the fact that although the fluid extract and tincture represent the virtues of cimicifuga, the alcohol present in both is therapeutically contra-indicated, and the exceedingly disagreeable taste of the drug is entirely masked if the extract be prescribed in the form of a pill, with proper additions, such as extract of liquorice, or if the pill be coated or enclosed in a capsule. The dose of the extract is from three to ten grains (0·194 Gm. to 0·648 Gm.).

EXTRACTUM CIMICIFUGÆ FLUIDUM. U. S. (Br.) Fluid Extract of Cimicifuga.

(ĘX-TRĂC'TŲM CĬM-Į-CĬF'Ų-ĢÆ FLŪ'Į-DŬM.)

Extractum Cimicifugæ Liquidum, *Br.;* Liquid Extract of Cimicifuga; Liquid Extract of Actæa Racemosa; **Extrait liquide d'Actée à Grappes,** *Fr.;* **Flüssiges Cimicifuga-Extrakt,** *G.*

" Cimicifuga, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims]

of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Cimicifuga is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Cimicifuga, in No. 60 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (90 per cent.), *a sufficient quantity.* Mix the Cimicifuga with *two pints* (Imp. meas.) or two thousand cubic centimetres of the Alcohol; set aside in a closed vessel for forty-eight hours; transfer to a percolator; when the fluid ceases to pass, continue the percolation with more Alcohol, until the Cimicifuga is exhausted. Reserve the first *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the percolate; evaporate the remainder to the consistence of a soft extract; dissolve this in the reserved portion; add enough of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

This formula does not differ essentially from that of the U. S. Pharm. 1870. The British preparation has been modelled after that of the United States. There probably cannot be two opinions about the menstruum, although it has been asserted that a good fluid extract can be made with a menstruum of three parts alcohol and one part water. The probabilities are, however, that a portion of the resinous principle would precipitate on standing. This fluid extract is of a deep reddish-brown color, and thoroughly represents the drug. The dose is from thirty minims to one fluidrachm (1·9 to 3·75 C.c.).

EXTRACTUM CINCHONÆ. U. S. Extract of Cinchona.

(ĘX-TRĂC'TUM CĬN-ȻHŌ'NÆ.)

Extractum Chinæ; Extrait de Quinquina jaune, *Fr.;* **China-Extrakt,** *G.*

"Cinchona, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *three thousand cubic centimeters* [or 101 fluidounces, 212 minims]; Water, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]; Diluted Alcohol, *a sufficient quantity.* Mix the Alcohol and Water, and having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until *four thousand cubic centimeters* [or 135 fluidounces, 122 minims] of tincture are obtained, or the Cinchona is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

The present official process is an excellent one, and if proper care be taken in executing the process, both in relation to the percolation and the avoidance of too high a temperature, the extract will fully represent the virtues of the bark.

The former extracts of cinchona of the British Colleges are all omitted in the British Pharmacopœia, which directs in their place a fluid extract, under the name of *Extractum Cinchonæ Liquidum.* (See next article.)

Medical Uses. The extract of Peruvian bark is at present much less employed than before the discovery of quinine. It is still, however, occasionally prescribed as a tonic in combination with other medicines. The dose is from ten to thirty grains (0·65–1·95 Gm.), equivalent to about a drachm (3·9 Gm.) of the powdered bark.

EXTRACTUM CINCHONÆ FLUIDUM. U. S. (Br.) Fluid Extract of Cinchona.

(ĘX-TRĂC'TUM CĬN-ȻHŌ'NÆ FLŪ'Ị-DŬM.)

"A Liquid Extract containing 5 grains of the alkaloids of Red Cinchona Bark in 110 minims (5 grammes in 100 cubic centimetres)." *Br.*

Extractum Cinchonæ Liquidum, *Br.,* **Liquid Extract of Cinchona; Extractum Chinæ Calisayæ Fluidum; Extrait liquide de Quinquina jaune,** *Fr.;* **Flüssiges Kalisayarinden-Extrakt,** *G.*

"Cinchona, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Alcohol, Water, each, *a*

sufficient quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator, and pour on the remainder of the menstruum. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, and, when the liquid in the percolator has disappeared from the surface, gradually pour on a mixture of Alcohol and Water, made in the proportion of *eight hundred cubic centimeters* [or 27 fluidounces, 34 minims] of Alcohol to *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and continue the percolation until the Cinchona is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of Alcohol and Water, using the same proportions as before, to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Red Cinchona Bark, in No. 60 powder, 20 *ounces* (Imperial) or 640 grammes; Hydrochloric Acid, 5 *fl. drachms* (Imp. meas.) or 20 cubic centimetres; Glycerin, 2½ *fl. ounces* (Imp. meas.) or 80 cubic centimetres; Alcohol (90 per cent.), Distilled Water, of each *a sufficient quantity*. Mix the Red Cinchona Bark with *five pints* (Imp. meas.) or three thousand two hundred cubic centimetres of the Distilled Water, to which the Hydrochloric Acid and Glycerin have been added; set aside in a covered vessel for forty-eight hours, stirring frequently; transfer to a percolator; when the liquid ceases to pass, and the contents of the percolator have been properly packed, continue the percolation with Distilled Water until *fifteen pints* (Imp. meas.) or nine thousand six hundred cubic centimetres of liquid have passed, or until that which is passing has ceased to give a precipitate on the addition to it of an excess of *solution of potassium hydroxide*. Evaporate the percolate in a porcelain or enamelled iron vessel at a temperature not exceeding 180° F. (82·2° C.), until it is reduced to *twenty fluid ounces* (Imp. meas.) or six hundred and forty cubic centimetres of liquid.

"Determine the proportion of alkaloids in the liquid product by the following analytical process:

"Put 5 cubic centimetres of the liquid, together with 25 cubic centimetres of *water*, into a stoppered glass separator; add 30 cubic centimetres of *benzolated amylic alcohol** and 15 cubic centimetres of *solution of potassium hydroxide;* shake them together thoroughly and repeatedly; allow them to remain at rest until the spirituous solution of the alkaloids shall have separated and formed a distinct stratum over the dark-colored alkaline liquid. Run off the latter by the stop-cock into another separator; agitate it thoroughly with 30 cubic centimetres of *benzolated amylic alcohol;* allow the liquids to separate; draw off and reject the lower layer; add the alcoholic layer to the liquid in the first separator; wash the mixture with a little *water;* agitate thoroughly with 30 cubic centimetres of a warm mixture of 1 volume of *diluted hydrochloric acid* and 5 volumes of *water;* allow the liquids to separate; draw off the lower acid layer into another separator; agitate the alcoholic layer with a second quantity of 30 cubic centimetres of the mixture of *water* and *diluted hydrochloric acid;* when separated draw this off into the other portion of acid liquid; to the mixture add 10 cubic centimetres of *chloroform* and sufficient *solution of ammonia* to impart a strongly alkaline reaction; shake thoroughly; allow the liquids to separate; draw off the lower chloroformic layer into a weighed dish; repeat the agitation and separation with two successive quantities of 10 cubic centimetres of *chloroform*, and add the chloroformic liquids to that in the dish. Allow the *chloroform* to evaporate slowly; dry the residue in the dish at a temperature of about 230° F. (110° C.). The weight of the dish and its contents, after deducting the known weight of the dish, will give that of the alkaloids.

"Having thus ascertained the alkaloidal strength of the *twenty fluid ounces* (Imp. meas.) or 640 cubic centimetres of liquid product, every volume of it containing 5 grammes of total alkaloids is first to be brought to 85 cubic centimetres either by evaporation or, if necessary, by dilution with Distilled Water, then a volume of 12·5 cubic centimetres of the Alcohol is to be added, and the final adjustment of the volume to 100 cubic centimetres is to be effected by the addition of Distilled Water. The finished Liquid Extract will thus contain 5 grammes of the alkaloids of the Bark in every 100 cubic centimetres, or 5 grains in 110 minims." *Br.*

* Made by mixing together three measures of benzol and one measure of amylic alcohol.

Of these two formulas, the first is decidedly preferable. It is based upon that of Mr. Alfred B. Taylor, of Philadelphia. (*A. J. P.*, Jan. 1865.) The British Pharmacopœia uses acidulated water with glycerin as a solvent, while it adds alcohol to the liquid to preserve it. In the U. S. process a mixture of alcohol and glycerin is used as the menstruum. Now, it is well known that cinchona cannot be properly exhausted by the British solvent; and, though by its use as a menstruum the resin and cinchonic red are mainly left behind, so also is a considerable proportion of the alkaloids. By using alcohol and glycerin, the U. S. Pharmacopœia extracts all the virtues of the bark, though it may also take up some of the resin and cinchonic red. The process of the British Pharmacopœia yields a preparation which would be more appropriately termed an "alkaloidal solution of cinchonas." The U. S. fluid extract, like others of its class, is a preparation which represents all of the soluble active constituents of cinchona; the British liquid extract, although an improvement on the former process, is simply a "preserved infusion" made by prolonged evaporation; the improvement consists in the addition of acid to the menstruum and the assaying of a portion of the evaporated percolate by a process similar to that adopted by the British Pharmacopœia for cinchona and making the finished product contain 5 per cent. of mixed alkaloids; thus any imperfections in the manipulation are overcome by the check of the assay; but it is doubtful whether a better preparation, and one involving much less complication, could not be made by dissolving definite quantities of the commercial alkaloids in a mixture of water, alcohol, acid, and glycerin. In this there would be the advantage of knowing the exact proportion of each constituent.* The U. S. fluid extract of cinchona is a moderately thin, dark reddish brown, translucent fluid, of a bitter, astringent taste. The dose equivalent to a drachm (3·9 Gm.) of the bark is one fluidrachm (3·75 C.c.); and to produce an antiperiodic effect at least two fluidounces (60 C.c.) should be taken between the paroxysms. The dose of the British liquid extract is from five to ten minims (0·3–0·6 C.c.).

EXTRACTUM COCÆ FLUIDUM. U. S. (Br.) Fluid Extract of Coca.

(EX-TRĂC'TUM CŌ'ÇÆ FLŪ'I-DŬM.)

Extractum Cocæ Liquidum, *Br.;* Liquid Extract of Coca; Extrait liquide de Coca, *Fr.;* Flüssiges Cocablätter-Extrakt, *G.*

"Coca, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred and fifty cubic centimeters* [or 15 fluidounces, 103 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Coca is exhausted. Reserve the first *eight hundred cubic centimeters* (or 27 fluidounces, 24 minims) of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Coca Leaves, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (60 per cent.), *a sufficient quantity*. Mix the powdered Coca Leaves with *two pints* (Imp. meas.) or two thousand cubic centimetres of the Alcohol; set aside in a closed vessel for forty-eight hours; transfer to a percolator; when the fluid ceases to pass, continue the percolation with more of the Alcohol until the Coca Leaves are exhausted. Reserve the first *fifteen fluid ounces* (Imp. meas.) or seven hundred and fifty cubic centimetres of the percolate; evaporate the remainder, at a temperature below 176° F. (80° C.), to the consistence of a soft extract; dissolve this in the reserved portion; add enough of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

This fluid extract is one of the most useful of the preparations of coca. L. F. Kebler prefers as a menstruum 65 per cent. alcohol and No. 60 powder in making this fluid extract. (*Proc. A. P. A.*, 1895, 339; see also *A. J. P.*, 1896, 609; *P. J. Tr.*, 1896, 306.) It is of a dark greenish-brown color, of an agreeable tea-like taste, but with little odor. The dose is from twenty minims to a fluidrachm (1·25–3·75 C.c.).

* *Liquid Extract of Cinchona* (simplified). Take of Quinine 75 grains, Cinchonidine 35 grains, Cinchonine 20 grains, Hydrochloric Acid 40 minims, Glycerin 5 fluidrachms, Alcohol 1 fluidrachm. Dissolve the alkaloids in the alcohol and glycerin mixed with 5 fluidounces of water, add the acid, agitate until dissolved, and add sufficient water to make 6 fluidounces. If the color and flavor of the bark are desired, add 60 grains of Red Cinchona in powder to the solution, allow it to stand 24 hours, then filter.

EXTRACTUM COLCHICI. Br. Extract of Colchicum.

(ĘX-TRĂC'TUM CŎL'ȻHĮ-CĪ.)

Extrait de Colchique, *Fr.;* Zeitlosen-Extrakt, *G.*

"Crush fresh Colchicum Corms, deprived of their coats; press out the juice; allow the feculence to subside; decant; heat the clear liquid to 212° F. (100° C.); strain through flannel, and evaporate at a temperature not exceeding 160° F. (71·1° C.) to the consistence of a soft extract." *Br.*

There scarcely seems to be occasion for both this and the following extract. The dose is from one to two grains (0·065–0·13 Gm.).

In Great Britain a preparation called *preserved juice of colchicum* is given in the dose of five minims (0·3 C.c.) or more. It is made by expressing the fresh bulb, allowing the juice to stand for forty-eight hours that the feculent matter may subside, then adding one-quarter of its bulk of alcohol, allowing it again to stand for a short period, and ultimately filtering.

EXTRACTUM COLCHICI RADICIS. U. S. Extract of Colchicum Root.

(ĘX-TRĂC'TUM CŎL'ȻHĮ-CĪ RĄ-DĪ'CĪS.)

Acetic Extract of Colchicum; Extrait de Colchique acétique, *Fr.;* Zeitlosen Essigextrakt, *G.*

"Colchicum Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims]; Water, *a sufficient quantity.* Mix the Acetic Acid with *fifteen hundred cubic centimeters* [or 50 fluidounces, 346 minims] of Water, and, having moistened the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture, pack it moderately in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Water, until the Colchicum Root is exhausted. Evaporate the percolate in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 80° C. (176° F.), to a pilular consistence." *U. S.*

As the fresh colchicum bulb is rarely to be had in this country, the U. S. Pharmacopœia employs the dried bulb; and its process, if properly conducted, will afford a very efficient extract. In preparing this extract according to the British process, by expression from the recent bulb, there will be experienced some inconveniences, which would seem to render the U. S. process under all circumstances preferable. (*P. J. Tr.*, xiii. 62.) The acetic extract of colchicum made from fresh corms was abandoned by the Br. Ph. 1898. The acetic acid in the U. S. preparation is a good solvent for colchicine. Dose, from one to two grains (0·065–0·13 Gm.).

EXTRACTUM COLCHICI RADICIS FLUIDUM. U. S. Fluid Extract of Colchicum Root.

(ĘX-TRĂC'TUM CŎL'ȻHĮ-CĪ RĄ-DĪ'CĪS FLŪ'Į-DŬM.)

Extrait liquide de Bulbe de Colchique, *Fr.;* Flüssiges Zeitlosenknollen-Extrakt, *G.*

"Colchicum Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Colchicum Root is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is not essentially different from that formerly official. The present menstruum will thoroughly exhaust the root, and this fluid extract is now a good preparation. It is of a reddish-brown color and bitter taste. Dose, from two to eight minims (0·12–0·5 C.c.).

EXTRACTUM COLCHICI SEMINIS FLUIDUM. U. S. Fluid Extract of Colchicum Seed.

(ĘX-TRĂC'TUM CŎL'CHI-CĪ SĔM'I-NĬS FLŪ'I-DŬM.)

Extrait liquide de Semences de Colchique, *Fr.;* Flüssiges Zeitlosensamen-Extrakt, *G.*

"Colchicum Seed, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Colchicum Seed is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The use of glycerin in this fluid extract (U. S. P. 1870) was even more objectionable than in that of the root, as the fixed oil contained in the seeds was always thrown out of solution, and was usually found floating on the fluid extract, rendering the preparation unsightly. L. I. Morris (*A. J. P.*, 1881, 7) believes that it is unnecessary to grind the colchicum seeds, and that if the whole seeds are digested with diluted alcohol at 80° C. (176° F.) the colchicine is easily extracted.

Considering that we had one tincture, two wines, and two extracts of colchicum, all efficient preparations requiring small doses, these additions to our pharmacy might have been spared, unless some peculiar advantage could have been gained from them. They are, however, efficient, concentrated preparations. Dose, from two to eight minims (0·12–0·5 C.c.).

EXTRACTUM COLOCYNTHIDIS. U. S. Extract of Colocynth.

(ĘX-TRĂC'TUM CŎL-Ọ-CŸN'THI-DĬS.)

Extrait de Coloquinte, *Fr.;* Koloquinten-Extrakt, *G.*

"Colocynth, dried, and freed from the seeds, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*. Reduce the Colocynth to a coarse powder by grinding or bruising, and macerate it in *thirty-five hundred cubic centimeters* [or 118 fluidounces, 167 minims] of Diluted Alcohol for four days, with occasional stirring; then express strongly, and strain through flannel. Pack the residue, previously broken up with the hands, firmly in a cylindrical percolator, cover it with the strainer, and gradually pour Diluted Alcohol upon it until the tincture and expressed liquid, mixed together, measure *five thousand cubic centimeters* [or 169 fluidounces, 33 minims]. Distil off the Alcohol from the mixture by means of a water-bath, evaporate the residue to dryness, and reduce the dry mass to powder. Extract of Colocynth should be kept in well-stoppered bottles." *U. S.*

Colocynth should be deprived of its seeds, as directed by the U. S. Pharmacopœia, before being submitted to the action of the menstruum. Dr. Duncan found half a pound of colocynth to contain 2770 grains of seeds, which, boiled by themselves, yielded almost nothing to water. Dr. Squibb found selected fruits to yield from 25·8 to 34 per cent. of medullary part, and this, when well exhausted by diluted alcohol, to yield 60·7 to 60·8 per cent. of dry extract; while from the whole fruit, including pulp and seeds, from 15·69 to 20·6 per cent. was obtained, according to the degree of dryness. (*A. J. P.*, 1857, p. 98.) Boiling water extracts so much pectin and mucilage from colocynth that either the decoction or hot infusion gelatinizes on cooling; and the extract made by means of it is loaded with inert matter, and, besides, is apt to become mouldy, or so tough and hard as to resist trituration and formation into pills. Hence the London College, following in this respect the French Codex, directed, in the last edition of its Pharmacopœia, maceration with cold water; but diluted alcohol has been found to be a much better menstruum, and has been adopted in the U. S. process; while in the British Pharmacopœia the simple extract has been discarded altogether. The chief, if not exclusive, use of the alcoholic extract is in the preparation of the compound extract.

This preparation should never be substituted for an extract prepared with a more aqueous menstruum, because water extracts a large quantity of mucilaginous and inert matter. Commercial extract of colocynth may be often found in the market made with an aqueous menstruum.

EXTRACTUM COLOCYNTHIDIS COMPOSITUM. U. S., Br. Compound Extract of Colocynth.

(ĘX-TRĂC'TUM CŎL-Ǫ-CŸN'THI-DĪS CǪM-PŎŞ'I-TŬM.)

Extrait de Coloquinte composé, *Fr.;* Zusammengesetztes Koloquinten-Extrakt, *G.*

"Extract of Colocynth, *one hundred and sixty grammes* [or 5 ounces av., 282 grains]; Purified Aloes, *five hundred grammes* [or 17 ounces av., 278 grains]; Cardamom, in No. 60 powder, *sixty grammes* [or 2 ounces av., 51 grains]; Resin of Scammony, in fine powder, *one hundred and forty grammes* [or 4 ounces av., 410 grains]; Soap, dried and in coarse powder, *one hundred and forty grammes* [or 4 ounces av., 410 grains]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Heat the Aloes, contained in a suitable vessel, on a water-bath, until it is completely melted; then add the Alcohol, Soap, Extract of Colocynth, and Resin of Scammony, and heat the mixture at a temperature not exceeding 120° C. (248° F.), until it is perfectly homogeneous, and a thread taken from the mass becomes brittle when cool. Then withdraw the heat, thoroughly incorporate the Cardamom with the mixture, and cover the vessel until the contents are cold. Finally, reduce the product to a fine powder. Compound Extract of Colocynth should be kept in well-stoppered bottles." *U. S.*

"Colocynth Pulp, 6 *ounces* (Imperial) or 150 grammes; Extract of Barbados Aloes, 12 *ounces* (Imp.) or 300 grammes; Scammony Resin, 4 *ounces* (Imp.) or 100 grammes; Curd Soap, in shavings, 4 *ounces* (Imp.) or 100 grammes; Cardamom Seeds, in the finest powder, 1 *ounce* (Imp.) or 25 grammes; Alcohol (60 per cent.) 1 *gallon* (Imp. meas.) or 4 litres. Macerate the Colocynth Pulp in the Alcohol for four days; press out the tincture; remove the alcohol by distillation; add the Extract of Aloes, Scammony Resin, and Soap; evaporate to the consistence of a firm extract, adding the Cardamoms towards the end of the process." *Br.*

The Br. Pharm. (1898) substituted Barbados aloes for the Socotrine variety, and increased the proportion of soap from three ounces to four ounces. The object of the soap is to improve the consistence of the mass, which, when hardened by time, it renders more soluble in the liquors of the stomach. It may possibly also serve the purpose of qualifying the action of the aloes. In the U. S. process the extract is in the form of powder, which is very convenient for admixture with other substances; while if given uncombined, it may be readily made into pills by suitable additions. The alternative of using the scammony or its resin, in the first British formula, which appeared to us very objectionable, has been abandoned in the present edition, and the resin only directed. It was objected to the U. S. compound extract of 1860 that it was apt to gripe in consequence of deficiency in the proportion of the aromatic ingredient, and the addition of some aromatic oil, as oil of cloves, was recommended: this was remedied in the revision of 1870 by increasing the proportion of cardamom. The plan of having the powders simply mixed was liable to the objection that the mixture was not apt to be so thoroughly effected as to obtain a uniform result; and hence the U. S. Pharm. of 1880 adopted Dr. Squibb's suggestion, to melt together all the ingredients unpowdered, except the cardamom, add a little alcohol, and, when the mixture is thoroughly made, to stir in the powdered aromatic, and finally to reduce the whole to a fine powder. The active principle of the cardamom (the volatile oil) is thus not dissipated, but absorbed by the other ingredients, and one of the objections to the British process is avoided,—*i.e.*, the necessity for directing cardamom in "the finest" powder, the previous desiccation of the cardamom, a requisite if a fine powder is desired, being very wasteful of the volatile oil.

This extract is an energetic and safe cathartic, possessing the activity of its three purgative ingredients, with comparatively little of the drastic character of the colocynth and scammony. It may be still further and advantageously modified by combination with rhubarb, jalap, calomel, etc., with one or more of which it is often united in prescription. In the dose of from one to two grains it is a good laxative. The purgative dose is from five to thirty grains (0·33–1·95 Gm.). We are informed that much of the extract sold in this country is made with inferior scammony and aloes and an insufficient proportion of colocynth, so that it is comparatively inert. Compound extract of colocynth should be looked on with suspicion when cheap, and the pharmacist should always prepare it for himself. (See *Amer. Drug.*, 1896, 152.)

EXTRACTUM CONII. U. S. Extract of Conium.

(ĘX-TRĂC'TUM CǪ-NĪ'Ī.)

Extract of Hemlock; Extrait de Ciguë, *Fr.;* Schierlings-Extrakt, *G.*

"Conium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *twenty cubic centimeters* [or 324 minims]; Diluted Alcohol, *a sufficient quantity.* Mix the

Acetic Acid with *nine hundred and eighty cubic centimeters* [or 33 fluidounces, 66 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or until the Conium is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], mix this with the reserved portion, and evaporate, at or below the above-mentioned temperature, to a pilular consistence." *U. S.*

Under the present name two extracts are now found in commerce, one, that of the U. S. P. (1890), an alcoholic extract made from conium fruit, the other, the British (1885) extract, made from the fresh leaves and young branches of the plant. In the U. S. extract acetic acid is used to fix the alkaloid coniine.

The most important point in making the Br. Ph. (1885) extract is to evaporate the juice without an undue degree of heat. At a temperature of 100° C. (212° F.), or upwards, its active principle undergoes rapid decomposition, being converted into resinous matter and ammonia. This is detected by the operator by the ammoniacal odor mixed with that which is peculiar to the plant. The juice always to a certain extent undergoes this decomposition when evaporated over a fire, and is not exempt from it even when the heat is regulated by a water-bath. Hence the propriety of the directions in the Br. Ph. (1885). An excellent plan in the evaporation is to conduct it first in a vacuum, and afterwards in shallow vessels with a current of air at common temperatures. By the direction to heat the juice to the boiling point, or 93·3° C. (200° F.) (*Br.*), and then to filter, whereby the inert albumen is coagulated, and, with the equally inert chlorophyll and vegetable fibre, is separated from the liquid before evaporation, the extract is procured in a more concentrated state, and, besides, deprived of substances which might favor its decomposition. Long-continued exposure to the air is productive of the same result as too much heat, so that old extracts are frequently destitute of activity. (*Journ. de Pharm.*, xxii. 416.) No one of the extracts is more variable in its qualities than this. The season at which the herb is collected, the place and circumstances of its growth, the method of preparing the extract, are all points of importance, and are all too frequently neglected. (See *Conium.*) In this country the process has often been carelessly conducted; and large quantities of an extract prepared by boiling the plant in water and evaporating the decoction have been sold as genuine extract. The apothecary should always prepare the extract himself, or procure it from persons in whom he can have confidence. That imported from London has usually been considered the best. It is not improbable that, as suggested by Prof. Procter, the addition of a portion of acetic acid to the juice, before evaporation, might tend to fix the coniine, and enable it better to resist the influence of heat, than in its native combination. The activity of any specimen of the extract may be in some measure judged of by rubbing it with potassa, which, disengaging the coniine and rendering it volatile, gives rise to the peculiar mouse-like odor of that principle. If no odor be evolved under these circumstances, the extract may be deemed inert.

The extract of hemlock prepared without separating the chlorophyll has a fresh olive or green color. It should have a strong narcotic, somewhat fetid odor, and a bitterish saline taste. According to Brande, from three to five pounds are obtained from one cwt. of the leaves. M. Recluz got rather more than an ounce from sixteen ounces. Dose of the U. S. P. 1890 extract, from one-half to one grain (0·03–0·065 Gm.), of the British extract, two grains (0·13 Gm.), two, three, or four times a day, to be gradually increased *pro re nata;* in pill or solution.

EXTRACTUM CONII FLUIDUM. U. S. Fluid Extract of Conium.

(ĘX-TRĂC'TUM CO-NĪ'Ī FLŪ'Į-DŬM.)

Extractum Conii Fructûs Fluidum, *U. S.* 1870; Fluid Extract of Conium Seed; Extrait liquide de Fruit de Ciguë, *Fr.;* Flüssiges Schierlingsfrucht-Extrakt, *G.*

"Conium (fruit) in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *twenty cubic centimeters* [or 325 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Acetic Acid with *nine hundred and eighty cubic centimeters* [or 33 fluidounces, 66 minims] of Diluted Alcohol,

and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Conium is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The fluid extract of conium of the U. S. Pharmacopœia of 1860 was prepared from the leaves, and was, therefore, of necessity a very uncertain, if not for the most part inert, preparation. The alkaloid coniine is contained in very unequal proportions in the fresh leaves, and is so very volatile and destructible that in the dried leaves it may be altogether wanting. Dr. Wm. Manlius Smith (*A. J. P.*, xl. 459), as the result of an elaborate investigation, found that the immature fruits of conium are not only richer in the alkaloids than are the leaves, but are less variable in the proportion they contain, and have the coniine in them in such form that drying does not dissipate it. The superiority of the fluid extract of conium seed over the same preparation of the leaves was shown by Dr. Smith, and has been since abundantly confirmed by experience. The revisers of the Pharmacopœia of 1870 acted very wisely in abandoning the old for the new preparation. The present fluid extract is a dark brownish-green liquid having the mouse-urine odor and emitting a still stronger conium smell on the addition of potassa; any sample which fails to do this should be rejected as wanting in the alkaloid. Dr. Smith found sixteen minims (1 C.c.) of a fluid extract of the seed prepared by Dr. Squibb to produce violent symptoms. Dr. L. Wheeler, however, took thirty minims (1·9 C.c.) without experiencing any result. (*Boston Med. and Surg. Journ.*, June, 1870.) Dangerous results have followed from the administration of much smaller doses, and it would seem hardly safe to begin with a dose of more than five minims (0·3 C.c), to be increased *pro re nata*.

EXTRACTUM CONVALLARIÆ FLUIDUM. U. S. Fluid Extract of Convallaria.

(ĘX-TRĂC'TUM CŎN-VAL-LĀ'RI-Æ FLŪ'I-DŬM.)

"Convallaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Convallaria is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract which well represents the activity of convallaria. The dose is from five to fifteen minims (0·3–0·9 C.c.).

EXTRACTUM CUBEBÆ FLUIDUM. U. S. Fluid Extract of Cubeb.

(ĘX-TRĂC'TUM CŪ-BĒ'BÆ FLŪ'I-DŬM.)

Extrait liquide de Cubèbe, *Fr.;* Flüssiges Cubeben-Extrakt, *G.*

"Cubeb, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Cubeb is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate,

and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

Notwithstanding the fact that the oleoresin of cubeb thoroughly represents in a concentrated liquid form all the virtue of this drug, the alcoholic fluid extract is a useful preparation: it permits the administration of cubeb in aqueous or hydro-alcoholic mixtures where the oleoresin would not be admissible except in emulsion. It is a dark olive, translucent fluid, with the sensible properties of the drug. Dose, from ten to forty minims (0·6–2·5 C.c.).

EXTRACTUM CUSSO FLUIDUM. U. S. Fluid Extract of Kousso.

(ĘX-TRĂC'TŲM CŪS'SŌ FLŪ'Į-DŬM.)

Extractum Brayeræ Fluidum, *U. S.* 1880; Fluid Extract of Brayera; Fluid Extract of Kousso; Extrait liquide de Kousso, *Fr.;* Flüssiges Kosso-Extrakt, *G.*

"Kousso, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Kousso is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract, although possessing a very disagreeable bitter taste, well represents the activity of kousso: the bitter resinous principle upon which the anthelmintic virtues are now believed to depend is readily extracted by alcohol. This preparation should be of a dark green color. The objection to it is the large dose and the considerable quantity of strong alcohol which the patient gets: as it is best to give the remedy fasting, the stimulating action of the alcohol would be apt to be apparent. The dose is from one-half to one fluidounce (15–30 C.c.). An extract made by evaporating the fluid extract spontaneously would be a good preparation, and the objection to the alcohol could be thus overcome.

EXTRACTUM CYPRIPEDII FLUIDUM. U. S. Fluid Extract of Cypripedium.

(ĘX-TRĂC'TŲM ÇŸP-RĮ-PĒ'DĮ-Ī FLŪ'Į-DŬM.)

Extrait liquide de Cypripède jaune, *Fr.;* Flüssiges Gelbfrauenschuh-Extrakt, *G.*

"Cypripedium, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Cypripedium is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract well represents the drug, although its use is at present very limited. It is very dark reddish brown in color, and may be given in doses of fifteen minims (0·9 C.c.).

EXTRACTUM DIGITALIS. U. S. Extract of Digitalis.

(ĘX-TRĂC'TŲM DĬÇ-Į-TĀ'LĬS.)

Extrait alcoolique de Digitale, *Fr.;* Fingerhut-Extrakt, *G.*

"Digitalis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138

minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or the Digitalis is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, at a temperature not exceeding 50° C. (122° F.), to a pilular consistence." *U. S.*

This was first introduced into the U. S. Pharmacopœia of 1860, though less needed than many others; because the dose of digitalis itself is small, and very little can be gained on the point of strength, as the really valuable part of digitalis constitutes but a small proportion even of the extract, and might be altogether wanting without observably affecting the bulk. The same caution is used, in preparing this extract, against the injurious effects of heat as in the instance of the extract of conium. The extract now official does not differ essentially from that of U. S. P. 1870, with this exception, that, instead of percolating first with alcohol and then with diluted alcohol, a menstruum of two parts alcohol and one part water is now used, finishing with diluted alcohol. The alcoholic extract of digitalis contains all the virtues and may be used for all the purposes of the powdered leaves. According to Messrs. Vielguth and Nentwich, the amount of alcoholic extract obtained from dried digitalis by cold displacement is 27·1 per cent. (*A. J. P.*, May, 1859.) Dose, one-fourth of a grain (0·016 Gm.).

EXTRACTUM DIGITALIS FLUIDUM. U. S. Fluid Extract of Digitalis.

(ĘX-TRĂC'TŲM DĬĢ-Ị-TĀ'LĬS FLŪ'Ị-DŬM.)

Extrait liquide de Digitale, *Fr.;* **Flüssiges Fingerhut-Extrakt,** *G.*

"Digitalis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Digitalis is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is dark greenish black in color, and represents the drug thoroughly. The dose is from one to two minims (0·06–0·12 C.c.).

EXTRACTUM DULCAMARÆ FLUIDUM. U. S. Fluid Extract of Dulcamara.

(ĘX-TRĂC'TŲM DŬL-CẠ-MĀ'RÆ FLŪ'Ị-DŬM.)

Extrait liquide de Douce-Amère, *Fr.;* **Flüssiges Bittersüss-Extrakt,** *G.*

"Dulcamara, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Dulcamara is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract;

dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The present formula differs from that of the U. S. P. 1870 in the absence of glycerin. This fluid extract is a rather thick, dark brown liquid. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.), three or four times a day, gradually increased if necessary.

EXTRACTUM ERGOTÆ. U. S., Br. Extract of Ergot.

(ĘX-TRĂC'TŲM ĔR'GŌ-TÆ.)

Ergotin, *Br.* **(1898); Extrait de Seigle ergoté,** *Fr.;* **Mutterkornextrakt,** *G.*

"Fluid Extract of Ergot, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]. Evaporate the Fluid Extract of Ergot in a porcelain capsule, by means of a water-bath, at a temperature not exceeding 50° C. (122° F.), constantly stirring until it is reduced to a pilular consistence." *U. S.*

"Ergot, in No. 40 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (60 per cent.), *a sufficient quantity;* Distilled Water, *a sufficient quantity;* Diluted Hydrochloric Acid, 7½ *fl. drachms* (Imp. meas.) or 47 cubic centimetres; Sodium Carbonate, 175 *grains* (Imp.) or 20 grammes. Moisten the powdered Ergot with *ten fluidounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack the damp powder in a percolator; percolate with the Alcohol until the Ergot is exhausted. Evaporate the percolate to *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres; add *five fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Distilled Water; filter when cold, washing the residue with a little Distilled Water. Add the Diluted Hydrochloric Acid to the filtrate; set aside for twenty-four hours; filter; wash the residue with Distilled Water until the washings no longer have an acid reaction, adding the washings to the filtrate; add the Sodium Carbonate to the latter; evaporate to a soft extract." *Br.*

The present preparation leaves little to be desired. The British preparation is modelled upon Keller's process. (*Schweiz. Wochen. f. Pharm.*, 1894, 141.) The object of the addition of hydrochloric acid is to precipitate out the flocculent sclererythrin, the coloring matter of ergot. The sodium carbonate neutralizes the acid, a small quantity of sodium chloride remaining in the extract. This is much the best preparation of ergot, being the only one that should be used hypodermically, and much less apt to cause nausea when given by the mouth. For method of hypodermic use, see *Ergota*. It is well adapted for suppositories, and has been applied topically to the os uteri, the desired dose being put on a dossil of absorbent cotton. Internally it is best given in gelatin capsules, since pills are apt to flatten. Dose, one-fifth that of the fluid extract or drug,—*i.e.*, from five grains to half a drachm (0·33–1·9 Gm.).

EXTRACTUM ERGOTÆ FLUIDUM. U. S. (Br.) Fluid Extract of Ergot.

(ĘX-TRĂC'TŲM ĔR'GŌ-TÆ FLŪ'Į-DŬM.)

Extractum Ergotæ Liquidum, *Br.;* **Liquid Extract of Ergot; Extrait liquide de Seigle ergoté,** *Fr.;* **Flüssiges Mutterkornextrakt,** *G.*

"Ergot, recently ground and in No. 60 powder, *one thousand grammes* [or 35 ounces av.. 120 grains]; Acetic Acid, *twenty cubic centimeters* [or 325 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Acetic Acid with *nine hundred and eighty cubic centimeters* [or 33 fluidounces, 66 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the mixture to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding the menstruum, until the Ergot is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Ergot, crushed, 20 *ounces* (Imperial) or 400 grammes; Distilled Water, 7½ *pints* (Imp. meas.) or 3000 cubic centimetres; Alcohol (90 per cent.), 7½ *fl. ounces* (Imp. meas.) or 150 cubic centimetres. Digest the crushed Ergot in *five pints* (Imp. meas.) or two thousand cubic centimetres of the Distilled Water for twelve hours; draw off the infusion; repeat the

digestion with the remainder of the Distilled Water; press; strain; evaporate the liquid to *fourteen fluid ounces* (Imp. meas.) or two hundred and eighty cubic centimetres; when cold, add the Alcohol; set aside for an hour; filter. The product should measure *twenty fluid ounces* (Imp. meas.) or four hundred cubic centimetres." *Br.*

This fluid extract was first suggested by Mr. Joseph Laidley, of Richmond, Va.; but the process has since been much modified. The improvement first suggested by Prof. Procter, of adding an acid to the menstruum to fix the alkaloids, and the selection of the proper menstruum, placed this important preparation at once on a permanent footing; and his original formula, published in 1857, and made official in 1860, is now practically adopted in 1890, notwithstanding the numerous changes of views concerning the active constituents of ergot. Practical experience has shown that it is not only a reliable preparation, but also, if carefully made, a permanent one. The use of glycerin in the menstruum is of no benefit whatever, and it would render the fluid extract unfit for use as a basis for the extract now official; as an addition, diluted hydrochloric has been replaced by acetic acid for fixing alkaloids, which makes the fluid extract of the U. S. P. 1890 identical with Prof. Procter's original formula. (See *Ergota.*) Diluted alcohol dissolves all the active matter of ergot, leaving its oil behind, and the tincture first obtained, holding most of the active principles, is reserved without concentration. In the British process the prolonged digestion and evaporation must act disadvantageously upon principles which are known to be very easily affected by heat and exposure. Bernagan and Burkhart have devised a process in which the fluid extract contains 5 per cent. of sodium chloride. The advantages are not apparent. (*Apoth. Zeit.*, 1895, 309.)

The U. S. fluid extract of ergot is a clear, very dark reddish-brown liquid, having the taste of ergot, but without its fishy odor, owing to the solution of the trimethylamine, upon which that odor depends. On the addition, however, of solution of potassa, the odor is strongly developed, and the alkaloid escapes so largely that, if hydrochloric acid be held near it, a cloud of trimethylamine chloride will be perceived. This may be considered as a good test of the efficiency of the preparation; for, though the virtues of ergot do not depend on its volatile alkaloid, yet if this be retained in the fluid extract there can be little doubt that the other more fixed principles will be retained also. The preparation is an active one, but in large doses it is more apt to sicken the stomach than is the simple extract. The dose is from half a fluidrachm to half a fluidounce (1·9–15 C.c.).

EXTRACTUM ERIODICTYI FLUIDUM. U.S. Fluid Extract of Eriodictyon.

(ĘX-TRĂC'TUM ĔR-I-Ō-DĬC'TY-Ī FLŪ'I-DŬM.)

"Eriodictyon, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eriodictyon is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract;* it has a dark brownish-green color, and will doubtless prove a valuable addition. The dose is from twenty minims to a fluidrachm (1·3–3·75 C.c.).

* *Aromatic Fluid Extract of Yerba Santa* (Edel's process). Take of fl. ext. yerba santa, fl. oz. 2; oil cloves, gtt. 32; oil orange, gtt. 16; oil sassafras, gtt. 16; alcohol, fl. oz. 3; liquor potassæ, fl. dr. 12; fl. ext. cardamom comp., fl. dr. 4; water, fl. oz. 4; glycerin, purified talcum, of each a sufficient quantity. The fluid extracts and oils are mixed, the solution of potassa and water added, then some talcum, and finally the alcohol, when the mixture is filtered, returning the first filtrate until it passes clear. Sufficient glycerin is then added to the filtrate to make one pint. The preparation is readily miscible with water, elixirs, or syrups. This fluid extract (so called) is intended for making a palatable Aromatic Syrup of Yerba Santa. (*Proc. A. P. A.*, 1897, 423.)

EXTRACTUM EUCALYPTI FLUIDUM. U.S. Fluid Extract of Eucalyptus.

(EX-TRĂC'TUM EŪ-CA-LŸP'TĪ FLŪ'I-DŬM.)

Extrait liquide d'Eucalyptus, *Fr.;* **Flüssiges Eucalyptus-Extrakt,** *G.*

"Eucalyptus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Eucalyptus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract well represents the drug, and is of a dark greenish-brown color, having the peculiar odor and taste of eucalyptus very strongly developed, but for administration it is much inferior to the volatile oil. The dose is from five to ten minims (0·3–0·6 C.c.).

EXTRACTUM EUONYMI. U.S. (Br.) Extract of Euonymus.

(ĘX-TRĂC'TUM EŪ-ŎN'Ỵ-MĪ.)

Extractum Euonymi Siccum, *Br.;* **Dry Extract of Euonymus; Extrait de Fusain,** *Fr.;* **Spindelbaum-Extrakt,** *G.*

"Euonymus, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 70 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or the Euonymus is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and, having placed the residue in a porcelain capsule, evaporate it, on a water-bath, to a pilular consistence." *U. S.*

"Euonymus Bark, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity;* Calcium Phosphate, *a sufficient quantity*. Moisten the powdered Euonymus Bark with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack in a percolator; gradually pour on more of the menstruum until the Euonymus is exhausted; collect the liquid and evaporate the alcohol; thoroughly dry the residue; powder the product as far as possible and mix it with one-fourth of its weight of Calcium Phosphate, continuing the drying and powdering until a satisfactory preparation is obtained; then immediately transfer it to a well-closed bottle." *Br.* Dry extract of euonymus is commonly known as "*euonymin*." An efficient preparation in doses of from one to three grains (0·065–0·2 Gm.).

EXTRACTUM EUPATORII FLUIDUM. U.S. Fluid Extract of Eupatorium.

(ĘX-TRĂC'TUM EŪ-PA-TŌ'RĮ-Ī FLŪ'Į-DŬM.)

Extrait liquide d'Eupatoire, *Fr.;* **Flüssiges Durchwachsener Wasserhanf-Extrakt,** *G.*

"Eupatorium, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Di-

luted Alcohol, until the Eupatorium is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract will have but a limited use, although it well represents the drug, since boneset is chiefly employed in domestic medicine. It is of a dark greenish-brown color, and the dose may be stated as from twenty minims to a fluidrachm (1·25–3·75 C.c.).

EXTRACTUM FILICIS LIQUIDUM. Br. Liquid Extract of Male Fern.

(ĘX-TRĂC'TUM FĬL'I-CĬS LĬQ'UI-DŬM—lĭk'wę-dŭm.)

This being properly an oleoresin, will be considered under the head of the *Oleoresinæ*, to which the reader is referred. (See *Oleoresina Aspidii*, page 913.)

EXTRACTUM FRANGULÆ FLUIDUM. U. S. Fluid Extract of Frangula.

(ĘX-TRĂC'TUM FRĂN'GŬ-LÆ FLŪ'I-DŬM.)

Extrait liquide de Bourdaine, *Fr.;* Flüssiges Faulbaumrinde-Extrakt, *G.*

"Frangula, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *five hundred cubic centimeters* [or 16 fluidounces, 436 minims] of Alcohol with *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Frangula is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which has been quite largely used in this country. It is intended to be a laxative, but it is frequently disappointing, as the drug is rarely to be obtained of uniformly good quality. The fluid extract is of a dark reddish-brown color.* The dose is from ten to twenty minims (0·6–1·25 C.c.).

EXTRACTUM GELSEMII FLUIDUM. U. S. Fluid Extract of Gelsemium.

(ĘX-TRĂC'TUM ĢĘL-SĔM'I-Ī FLŪ'I-DŬM.)

Extrait liquide de Jasmin jaune, *Fr.;* Flüssiges Gelber Jasmin-Extrakt, *G.*

"Gelsemium, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Gelsemium is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is identical with the fluid extract formerly official, which has proved very useful. It is of a dark reddish-brown color. The dose is from two to three minims (0·12–0·18 C.c.).

* *Sweet Fluid Extract of Buckthorn* (Edel's process). Fld. extr. buckthorn, fl. oz. 16; solution of potassa, fl. dr. 1; solution of liquorice (N. F.), fl. oz. 2; saccharin, dr. 1. Take 3 fluid ounces of the fluid extract, reduce by evaporation to half a fluid ounce, dissolve in the rest of the fluid extract, add the solution of potassa, saccharin, and liquorice. The resulting product is a permanent sweet fluid extract. (*Proc. A. P. A.*, 1897, 423.)

EXTRACTUM GENTIANÆ. U. S., Br. Extract of Gentian.

(ĘX-TRĂC'TUM ĢĔN-TI-Ā'NÆ.)

Extrait de Gentiane, *Fr.;* **Enzian-Extrakt,** *G.*

"Gentian, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *a sufficient quantity.* Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water, and let it macerate for twenty-four hours; then pack it in a conical percolator, and gradually pour water upon it until the infusion passes but slightly imbued with the properties of the Gentian. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then, by means of a water-bath, evaporate to a pilular consistence." *U. S.*

"Infuse Gentian Root in ten times its weight of Distilled Water for two hours; boil for fifteen minutes; pour off; press; strain; evaporate the liquid to the consistence of a soft extract." *Br.*

The plan of percolation with cold water is admirably adapted to the extraction of the active matter of gentian. By the use of cold water, starch and pectic acid are left behind, while any albumen that may be taken up is disposed of by the subsequent boiling and straining.

The extract, however, may be advantageously made by macerating the root in two parts of water for thirty-six hours, then expressing in a powerful press, again macerating with additional water, and in like manner expressing, and evaporating the united expressed liquors. MM. Guibourt and Cadet de Vaux obtained by maceration in cold water an extract not only greater in amount, but also more transparent, more bitter, and possessing more of the color and smell of the root, than that prepared by decoction. Guibourt attributes this result to the circumstance that, as gentian contains little if any starch, it yields nothing to boiling which it will not also yield to cold water; while decoction favors the combination of a portion of the coloring matter with the lignin. But this opinion requires modification, now that it is understood that gentian contains pectic acid, which water will extract when boiling hot, but not when cold. Gentian, according to Brande, yields half its weight of extract by decoction.

As ordinarily procured, the extract of gentian has an agreeable odor, is very bitter, and of a dark brown color approaching to black, shining, and tenacious. It is frequently used as a tonic, in the form of pill, either alone or in connection with metallic preparations; but the practice of some pharmacists of using it indiscriminately as a pill excipient is very wrong and deserving of severe censure. The dose is from five to ten grains (0·33–0·65 Gm.).

EXTRACTUM GENTIANÆ FLUIDUM. U. S. Fluid Extract of Gentian.

(ĘX-TRĂC'TUM ĢĔN-TI-Ā'NÆ FLŪ'I-DŬM.)

Extrait liquide de Gentiane, *Fr.;* **Flüssiges Enzian-Extrakt,** *G.*

"Gentian, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Gentian is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms.]" *U. S.*

This is a translucent, reddish-brown fluid, with the smell and taste of the root. It may be questionable whether it was needed, though it has the advantage that we may obtain from it the tonic effects of the drug with less alcohol than in an equivalent quantity of the tincture; and pharmaceutically it affords a convenient method of giving to mixtures the tonic properties of gentian when required. The dose is from ten to thirty minims (0·6–1·9 C.c.).

EXTRACTUM GERANII FLUIDUM. U. S. Fluid Extract of Geranium.

(ĘX-TRĂC'TUM ĢĘ-RĀ'NI-Ī FLŪ'I-DŬM.)

Extrait de Bec de Grue tacheté, *Fr.;* **Flüssiges Fleckenstorchschnabel-Extrakt,** *G.*

"Geranium, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient*

quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough of the menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Geranium is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The quantity of glycerin has been greatly diminished in this fluid extract, and the process is now unobjectionable. It is a dark reddish-brown liquid, having little odor and a very astringent taste. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.). For *Stolz's process*, see *Registered Pharmacist*, 1893, 253.

EXTRACTUM GLYCYRRHIZÆ. U. S. Extract of Glycyrrhiza.

[Extract of Liquorice.]

(ĘX-TRĂC'TŲM GLĬÇ-ĮR-RHĪ'ZÆ—glĭs-ĵr-rī'zē.)

"The commercial extract of the root of Glycyrrhiza glabra, Linné (nat. ord. Leguminosæ)." *U. S.*

Succus Liquiritiæ, *P. G.;* Liquorice, Licorice; Extrait de Réglisse, *Fr.;* Lakriz, Lakrizensaft, Süssholzsaft, *G.;* Sugo di Liquirizia, *It.;* Regaliza en Ballos, *Sp.*

Liquorice is an article of export from the north of Spain, particularly Catalonia, where it is obtained in the following manner. The roots of the *G. glabra*, having been dug up, thoroughly cleansed, and half dried by exposure to the air, are cut into small pieces, and boiled in water till the liquor is saturated. The decoction is then allowed to rest, and, after the dregs have subsided, is decanted, and evaporated to the proper consistence. The extract, thus prepared, is formed into rolls from five to six inches long by an inch in diameter, which are dried in the air, and wrapped in laurel leaves.

The British Pharmacopœia gives a process for making extract of liquorice. (See page 568.) The U. S. Pharmacopœia directs that not less than 60 per cent. of it should be soluble in cold water.

Much liquorice is prepared in Calabria, according to M. Fée, from the *G. echinata*, which abounds in that country. The process is essentially the same as that just described, but conducted with greater care; and the Italian liquorice is purer and more valuable than the Spanish. It is in cylinders, generally somewhat smaller than the Spanish, and usually stamped with the manufacturer's brand. Most of the extract brought to this country comes from Messina and Catania in Sicily and Naples, from Seville and Saragossa in Spain, and from Smyrna in Turkey. Perhaps in no other part of the world is more liquorice consumed than in the United States, from four to five thousand tons having been imported annually before the war; but the article is now made on an extensive scale in this country, very successfully, with the best modern appliances, and of such good quality as to have almost driven the foreign article out of the market. The principal use of Extract of Liquorice is in the manufacture of chewing tobacco; that in the form of rolls as sold by the druggists being a comparatively small portion of the whole amount consumed.

Crude Liquorice, *Liquorice Paste*, or *Liquorice Mass*, as it is variously termed, is found in the market in cases ranging from two hundred and fifty to four hundred pounds, of a hard pilular consistence and, as its name implies, in a mass, which has been run into the case while hot and then allowed to cool.

Liquorice is usually in cylindrical rolls, somewhat flattened, and often covered with bay-leaves. We have seen it in the London market in large cubical masses. When good, it is very black, dry, brittle, breaking with a shining fracture, of a very sweet, peculiar, slightly acrid or bitterish taste, and almost entirely soluble, when pure, in boiling water. Neumann obtained 460 parts of aqueous extract from 480 parts of Spanish liquorice. It is, however, considerably less soluble in cold water. It is often impure from accidental or fraudulent addition or careless preparation. Starch, sand, the juice of prunes, etc., are sometimes added; and carbonaceous matter, and even particles of copper, are found in it, the latter arising from

the boilers in which the decoction is evaporated. Four pounds of the extract have yielded two drachms and a half of metallic copper. (*Fée.*) In different commercial specimens examined by Chevallier he found from 9 to 50 per cent. of insoluble matter. (*Journ. de Pharm.*, xxx. 429.) This is by no means, however, always impurity. In the preparation of the extract by decoction, a portion of matter originally insoluble, or rendered so by decoction, is taken up, and is, in fact, necessary to the proper constitution of the liquorice. When this is prepared with cold water, or even with hot water by simple displacement, the extract attracts moisture from the air, becomes soft, and loses the characteristic brittleness of the drug. The additional substances taken up in decoction serve to protect the extract against this change. M. Delondre has obtained the same result by using steam as the solvent. He prepares from the root an excellent liquorice, having all the requisite qualities of color, taste, and permanence, by passing steam, in suitable vessels, through the coarse powder of the root. The vapor thoroughly penetrates the powder, and is drawn off as it condenses. With about 500 lbs. of the root, this treatment is continued for twelve hours, and repeated at the end of five days. The liquors are collected, decanted, clarified with about 4 lbs. of gelatin, and quickly evaporated. After being put into the form of cylinders, the extract is kept for ten days in a drying-room, at a temperature of 77°. (*Ibid.*, p. 433.) A bitter or empyreumatic taste is a sign of inferior quality in liquorice. As ordinarily found in commerce, it requires to be purified.* (See *Extractum Glycyrrhizæ Purum;* also *Liquor Extracti Glycyrrhizæ*, PART II.)

Liquorice contains glycyrrhizin, $C_{24}H_{36}O_9$, a glucoside, partly free and partly in combination with ammonia, to which combination the characteristic sweet taste of liquorice is due. The glycyrrhizin when boiled with dilute acids decomposes into *glycyrrhetin*, $C_{18}H_{26}O_4$, and a fermentable sugar.

The *refined liquorice*, found in commerce in small cylindrical pieces not thicker than a pipe-stem, is prepared by dissolving the impure extract in water without boiling, straining the solution, and evaporating. The object of this process is to separate not only the insoluble impurities, but also the acrid oleoresinous substance which is extracted by long boiling from the liquorice root and is necessarily mixed with the unrefined extract. It is customary to add, during the process, a portion of sugar, gum, flour, starch, or perhaps glue. These additions, or something equivalent, are necessary to obviate the deliquescent property of the pure liquorice. According to M. Delondre, 15 per cent. of gum is the proper proportion, when this substance is used; Dr. Geisler has found sugar of milk to lessen the disposition of the extract to absorb moisture; but he considers the best addition, on the whole, to be very finely powdered liquorice root, which should be used in the proportion of 1 part to 16 of the purified extract. (*A. J. P.*, xxviii. 225.) The preparation is sometimes attacked by small worms, probably in consequence of the farinaceous additions. Excellent liquorice is prepared in some parts of England, from the root cultivated in that country. The *Pontefract cakes* are small lozenges of liquorice made in the vicinity of Pontefract, England. For methods of assaying extract of liquorice, see *A. J. P.*, 1896, 663; also 1898, 23, 136.

Medical Properties and Uses. Liquorice is a useful demulcent, much employed in cough mixtures, and frequently added to infusions or decoctions in order to cover the taste or

* The following results of an examination of different brands of liquorice in the market in relation to the proportion of matters soluble and those insoluble in cold water contained in them respectively, by Mr. L. J. Schroeder, are published in the *A. J. P.* (1884, p. 311). Five hundred grains of each commercial extract were used.

It will be seen that the American exceeds all the other brands in the amount of the sweet principle.

obtund the acrimony of the principal medicine. A piece of it held in the mouth and allowed to dissolve slowly is often found to allay cough by sheathing the irritated membrane of the fauces. It is used in pharmacy to impart consistence to pills and troches, and to modify the taste of other medicines.

EXTRACTUM GLYCYRRHIZÆ FLUIDUM. U. S. (Br.) Fluid Extract of Glycyrrhiza.

(ĘX-TRĂC'TUM GLĬÇ-ŸR-RHĪ'ZÆ FLŪ'Ĭ-DŬM.)

Extractum Glycyrrhizæ Liquidum, *Br.;* Liquid Extract of Liquorice; Extrait liquide de Réglisse, *Fr.;* Flüssiges Süssholz-Extrakt, *G.*

"Glycyrrhiza, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Ammonia Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Ammonia Water with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol and *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water made in the proportion of *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol and *six hundred and fifty cubic centimeters* [or 21 fluidounces, 470 minims] of Water, until the Glycyrrhiza is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of Alcohol and Water to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Liquorice Root, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Distilled Water, 5 *pints* (Imp. meas.) or 5 litres; Alcohol (90 per cent.), *a sufficient quantity.* Mix the Liquorice Root with half of the Distilled Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Distilled Water and set aside for six hours; strain; press; mix the strained liquids; heat to 212° F. (100° C.); strain through flannel; evaporate until the fluid has acquired, when cold, a specific gravity of 1·200; add to this one-fourth of its volume of the Alcohol; let the mixture stand for twelve hours; filter." *Br.*

The fluid extract of the U. S. Pharm. 1880 differed from that official in 1870 in the absence of glycerin in the menstruum, and in the presence of ammonia water, as suggested by Prof. J. P. Remington. (See *Proc. A. P. A.*, 1878, 757.) The British formula for the liquid extract has several inconvenient manipulative features, such as the repeated macerations and expressions, evaporating to a certain specific gravity, etc. (See *Montreal Pharm. Journ.*, 1893, 147; *P. J. Tr.*, 1898, 188.) This preparation is now very largely used as an adjuvant, and for disguising the bitter taste of quinine, which should be added to the preparation of liquorice just before the dose is taken. It is a very convenient form for using liquorice, the objections to the former fluid extracts of the root having been the slight acridity and the presence of too much alcohol. Not only does the ammonia render the glycyrrhizin soluble, thus materially adding to the power and sweetness of the fluid extract, but it also greatly lessens the acridity. It is a very dark reddish-brown liquid, having the well-known sweet taste of liquorice, and froths when shaken with water. A *syrup of liquorice* may be made by adding two parts of fluid extract to fourteen parts of simple syrup. For a formula for aromatic elixir of liquorice, see *Elixirs,* PART II.

EXTRACTUM GLYCYRRHIZÆ PURUM. U. S. (Br.) Pure Extract of Glycyrrhiza.

(ĘX-TRĂC'TUM GLĬÇ-ŸR-RHĪ'ZÆ PŪ'RŬM.)

Extractum Glycyrrhizæ, *Br.;* Extract of Liquorice; Extractum Glycyrrhizæ Depuratum, Succus Liquiritiæ Depuratus; Extrait de Réglisse pur, *Fr.;* Reines Lakriz, *G.*

"Glycyrrhiza, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Ammonia Water, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Distilled Water, *a sufficient quantity.* Mix the Ammonia Water with *three thousand cubic centimeters* [or

101 fluidounces, 212 minims] of Distilled Water, and, having moistened the powder with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of the menstruum, let it macerate for twenty-four hours. Then pack it moderately in a cylindrical glass percolator, and gradually pour upon it, first, the remainder of the menstruum, and then Distilled Water, until the Glycyrrhiza is exhausted. Lastly, evaporate the infusion, by means of a water-bath, to a pilular consistence." *U. S.*

"Liquorice Root, in No. 20 powder, 1 *pound* (Imperial) or 1000 grammes; Distilled Water, 4 *pints* (Imp. meas.) or 5 litres. Mix the Liquorice Root with *two pints* (Imp. meas.) or two and a half litres of the Distilled Water; set aside for twenty-four hours; strain; press; to the pressed marc add the remainder of the Distilled Water and set aside the mixture for six hours; strain; press; mix the strained liquids; heat to 212° F. (100° C.); strain through flannel; evaporate to the consistence of a soft extract." *Br.*

The necessity for a pure extract of liquorice must be apparent to every pharmacist: the very variable quality of the commercial extract has frequently led to disappointment. The official process affords a preparation which is unexceptionable, the ammonia rendering the glycyrrhizin soluble; yet care must be taken in its evaporation, as it is very easily injured by too much heat, which gives it an empyreumatic taste, destroying at once its usefulness as an agreeable adjuvant.

EXTRACTUM GOSSYPII RADICIS FLUIDUM. U. S. Fluid Extract of Cotton Root Bark.

(ĘX-TRĂC'TUM GOS-SĬP'Į-Ī RĄ-DĪ'CĪS FLŪ'Į-DŬM.)

Extrait liquide d'Ecorce de Cotonnier, *Fr.;* **Flüssiges Baumwollenwurzel-Extrakt,** *G.*

"Cotton Root Bark, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol, and, having moistened the powder with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Alcohol, until the Cotton Root Bark is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is one of the fluid extracts which is improved by the use of glycerin: the menstruum selected prevents the gelatinization which was a troublesome objection to the fluid extract of the Pharmacopœia of 1870. Prof. J. U. Lloyd prefers a menstruum composed of ten fluidounces of alcohol and three fluidounces each of glycerin and water, finishing the percolation with a mixture composed of ten fluidounces of alcohol and six fluidounces of water. It is a deep-reddish liquid, and well represents the root. The dose is from half a fluidrachm to a fluidrachm (1·9–3·75 C.c.).

EXTRACTUM GRINDELIÆ FLUIDUM. U. S. Fluid Extract of Grindelia.

(ĘX-TRĂC'TUM GRĬN-DĒ'LĮ-Æ FLŪ'Į-DŬM.)

"Grindelia, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Grindelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion.

and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which well represents the drug: owing to the large quantity of resinous matter present, it does not mix well with aqueous liquids. The menstruum in the present process has been made more alcoholic than that formerly used. The so-called "*alkaline fluid extract of grindelia*" may be made by evaporating one pint of official fluid extract till reduced to twelve fluidounces, making a solution of 180 grains of sodium bicarbonate in four fluidounces of water, adding it slowly to the evaporated fluid extract, and filtering. It is a dark brown liquid having the peculiar odor of grindelia. Dose, from half a fluidrachm to a fluidrachm (1·9–3·75 C.c.).

EXTRACTUM GUARANÆ FLUIDUM. U. S. Fluid Extract of Guarana.

(ĘX-TRĂC'TUM GUĄ-RĀ'NÆ FLŪ'Į-DŬM—gwą-rā'nē.)

"Guarana, in No. 80 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Guarana is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is of doubtful utility. The powdered drug itself is portable, not unpleasant to the taste, and is efficient when given diffused in water; nothing is gained by making it into a fluid extract. The fluid extract is of a deep reddish-brown color. (See *Proc. A. P. A.*, 1897, 423.) The dose is from one to two fluidrachms (3·75–7·5 C.c.).

EXTRACTUM HÆMATOXYLI. U. S. Extract of Hæmatoxylon.

(ĘX-TRĂC'TUM HÆ-MĄ-TŎX'Į-LĪ.)

Extract of Logwood; Extractum Ligni Campechiani, *P. G.;* Extrait de Bois de Campêche, *Fr.;* Campecheholz-Extrakt, *G.*

"Hæmatoxylon, rasped, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *ten thousand cubic centimeters* [or 338 fluidounces, 66 minims]. Macerate the Hæmatoxylon with the Water for forty-eight hours. Then boil (avoiding the use of metallic vessels) until one-half of the Water has evaporated; strain the decoction, while hot, and evaporate to dryness." *U. S.*

This is one of the few instances in which decoction in the preparation of extracts is not considered objectionable. Iron vessels should not be employed in the process, in consequence of the presence of tannic acid. The evaporation should be carried so far that the extract may be dry and brittle when cold. About 20 lbs. of it are obtained from one cwt. of logwood. (*Brande.*) It is of a deep ruby color, and an astringent, sweetish taste, and has all the medical virtues of the wood. If given in pills, these should be recently made, as when long kept they are said to become so hard as sometimes to pass unchanged through the bowels. The extract, however, is best administered in solution. The dose is from ten to thirty grains (0·65–1·95 Gm.). This extract is said to be prepared largely in Yucatan and other parts of Mexico.

EXTRACTUM HAMAMELIDIS FLUIDUM. U. S. (Br.) Fluid Extract of Hamamelis.

(ĘX-TRĂC'TUM HĂM-Ą-MĔL'Į-DĬS FLŪ'Į-DŬM.)

Extractum Hamamelidis Liquidum, *Br.;* Liquid Extract of Hamamelis.

"Hamamelis, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*. Mix the Glycerin with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol and *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11

fluidounces, 400 minims] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Alcohol to *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Water, until the Hamamelis is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Hamamelis Leaves, in No. 40 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powdered Hamamelis Leaves with about *eight fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Alcohol; pack the moistened powder in a percolator, and add sufficient menstruum to saturate it thoroughly; when the liquid begins to drop, close the lower orifice of the percolator; set aside for forty-eight hours; then allow percolation to proceed, gradually adding menstruum until the Hamamelis Leaves are exhausted; reserve the first *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of the percolate; remove the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient menstruum to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

This is a fluid extract, which well represents the virtues of witch-hazel. It has a dark reddish-brown color. The dose is half a fluidrachm (1·9 C.c.).

EXTRACTUM HYDRASTIS FLUIDUM. U. S. (Br.) Fluid Extract of Hydrastis.

(ĘX-TRĂC'TUM HĪ-DRĂS'TIS FLŪ'I-DŬM.)

Extractum Hydrastis Liquidum, *Br.;* Liquid Extract of Hydrastis; Extrait liquide de Hydrastis, *Fr.;* Flüssiges Hydrastis-Extrakt, *G.*

"Hydrastis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, until the Hydrastis is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Hydrastis Rhizome, in No. 60 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powdered Hydrastis with about *eight fluid ounces* (Imp. meas.) or four hundred cubic centimetres of the Alcohol; pack the damp powder in a percolator; pour on sufficient menstruum to saturate it thoroughly; when the liquid begins to drop, close the lower orifice of the percolator; set aside for forty-eight hours; then allow percolation to proceed, gradually adding menstruum until the Hydrastis is exhausted; reserve the first *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of the percolate; remove the alcohol from the remainder by distillation; evaporate the residue to a soft extract; dissolve this in the reserved portion; add sufficient menstruum to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

The fluid extract thoroughly represents the drug. It is of a deep brownish-yellow color, and may be given in doses of from one-half to one fluidrachm (1·87–3·75 C.c.).

EXTRACTUM HYOSCYAMI. U. S. (Br.) Extract of Hyoscyamus.

(ĘX TRĂC'TŲM HŸ-ǪS-CĪ'Ą-MĪ.)

Extractum Hyoscyami Viride, *Br.*, Green Extract of Hyoscyamus; Extract of Henbane; Extrait de Jusquiame, *Fr.*; Bilsenkraut-Extrakt, *G.*

"Hyoscyamus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms]; Water, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]; Diluted Alcohol, *a sufficient quantity.* Mix the Alcohol and Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then Diluted Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or the Hyoscyamus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, to a pilular consistence." *U. S.*

"Bruise fresh leaves, flowering tops, and young branches of Hyoscyamus niger, Linn.; press out the juice and heat it gradually to 130° F. (54·4° C.); separate the green coloring matter by a calico filter; heat the strained liquid to 200° F. (93·3° C.); filter. Evaporate the filtrate to the consistence of a thin syrup; add to it the green coloring matter previously separated and passed through a hair sieve; stir the whole together, and evaporate at a temperature not exceeding 140° F. (60° C.), to the consistence of a soft extract." *Br.*

MM. Solon and Soubeiran have shown that the insoluble matter separated from the expressed juice of henbane by filtering, and that coagulated by heat, are nearly if not quite inert; so that the juice may be usefully clarified before evaporation. (*A. J. P.*, viii. 228.) The retention of the chlorophyll, however, as provided for in the British formula, is thought to be advantageous. This kind of extract of henbane is chiefly derived from England. Mr. Brande says that one cwt. of the fresh herb affords between four and five pounds. M. Recluz obtained one part from sixteen.

The extract is of a dark olive color, of a narcotic rather unpleasant odor, and a bitterish, nauseous, slightly saline taste. It retains its softness for a long time, but at the end of three or four years becomes dry, and exhibits, when broken, small crystals of potassium nitrate and sodium chloride. (*Recluz.*) Like all the inspissated juices, it is of variable strength, according to its age, the care used in its preparation, and the character of the leaves. (See *Hyoscyamus.*)

Much depends on the choice of the leaves; and too little attention is paid to this point. In reference to the biennial plant, there seems to be no doubt that the leaves of the second year are much more efficacious than those of the first, and should, therefore, always be selected. It is stated under Hyoscyamus that the leaves should be gathered soon after the plant has flowered. Mr. Charles Cracknell gives more particular directions. He thinks the plant is in a fit state for collection during only a very short period, namely, when the flowers at the top are blown, but have not yet begun to fade, and the seed-vessels and seeds which have been formed are still soft and juicy. For other observations on the preparation of this extract, see a paper by Mr. Cracknell in *A. J. P.* (xxiii. 245). Mr. T. B. Groves found that an extract obtained by inspissating the juice of the stems was altogether inferior to another obtained in like manner from the leaves, being not only less in amount, but also lower in quality. (*P. J. Tr.*, 1862.)

The U. S. P. extract is a much more reliable and active preparation than the inspissated juice, or, as it is usually termed, English extract. It is of a dark olive color, with the peculiar odor of hyoscyamus. The dose is from one to two grains (0·065–0·13 Gm.). In the use of the English extract it is advisable to begin with a moderate dose, two or three grains (0·13 or 0·20 Gm.), and gradually to increase the quantity till some effect is experienced, and the degree of efficiency of the particular parcel employed is ascertained. It is usually given in pill.

EXTRACTUM HYOSCYAMI FLUIDUM. U. S. Fluid Extract of Hyoscyamus.

(ĘX-TRĂC'TŲM HŸ-ǪS-CĪ'Ą-MĪ FLŪ'Į-DŬM.)

Extrait liquide de Jusquiame, *Fr.*; **Flüssiges Bilsenkraut-Extrakt,** *G.*

"Hyoscyamus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces,

6½ fluidrachms]. Mix *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of Alcohol with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Hyoscyamus is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract was improved in the 1880 revision by abandoning the glycerin directed in the former process. It is of a very dark greenish-brown color, and is given in the dose of five minims (0·3 C.c.) to begin with. For the medical properties, see *Hyoscyamus.*

EXTRACTUM IPECACUANHÆ FLUIDUM. U. S. (Br.) Fluid Extract of Ipecac.

(ĘX-TRĂC'TUM ĬP-Ę-CĂC-Ū-ĂN'HÆ FLŪ'Į-DŬM—Ip-ę-kăk-yū-ăn'ē.)

"A Liquid Extract containing 2 to 2½ grains of the alkaloids of Ipecacuanha Root in 110 minims (2 to 2.25 grammes in 100 cubic centimetres)." *Br.*

Extractum Ipecacuanhæ Liquidum, *Br.*, Liquid Extract of Ipecacuanha; **Extrait liquide d'Ipécacuanha,** *Fr.*; **Flüssiges Ipecacuanha-Extrakt,** *G.*

"Ipecac, in No. 80 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Ipecac is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Ipecacuanha Root, in No. 20 powder, 1 *pound* (Imperial) or 800 grammes; Calcium Hydroxide, 700 *grains* (Imp.) or 80 grammes; Alcohol (90 per cent.), *a sufficient quantity.* Moisten the powdered Ipecacuanha Root with *six fluid ounces* (Imp. meas.) or three hundred cubic centimetres of the Alcohol; pack firmly in a percolator; add more of the Alcohol, and when the liquid begins to drop, close the lower orifice of the percolator; set aside for twenty-four hours. Then percolate slowly until *thirteen and a half fluid ounces* (Imp. meas.) or six hundred and seventy-five cubic centimetres have been collected; reserve this portion. Continue percolation until nothing more is extracted; drain well. Mix the Lime with the marc; allow them to remain in contact for twenty-four hours; then continue percolation until exhaustion is complete. Recover the alcohol from the last two percolates by distillation; dissolve the residual extract in the reserved portion of percolate.

"Determine the proportion of alkaloids in the resulting strong liquid extract by the following analytical process:

"Dilute 20 cubic centimetres with an equal bulk of *water.* Remove the alcohol by the aid of a water-bath; add to the warm solution an excess of *solution of lead subacetate.* Filter; wash the precipitate with water and add the washings to the filtrate. Remove the excess of lead from the filtrate by precipitation with *diluted sulphuric acid;* filter; wash the precipitate with water and add the washings to the filtrate. Transfer the filtrate to a separator; add excess of *solution of ammonia* and agitate with 25 cubic centimetres of *chloroform.* Separate and set aside the chloroformic solution. Twice repeat the agitation with chloroform, and the separation. Mix the chloroformic solutions; evaporate; dry at a temperature below 176° F. (80° C.), and weigh the residue of total alkaloids.

"From this weight calculate the amount of alkaloids in the bulk of strong liquid extract, and add to the latter sufficient Alcohol (90 per cent.) to produce Liquid Extract of Ipecacuanha containing not less than 2 and not more than 2·25 grammes of alkaloid in 100 cubic centimetres, or from 2 to 2¼ grains in 110 minims." *Br.*

The menstruum for the U. S. fluid extract has been altered, it having been proved by J. U. Lloyd that when alcohol alone is used a portion of emetine escapes solution. On the other hand, it is known that when the menstruum is more aqueous more of the pectinous principles are taken up, and it is very desirable to separate these in order to prevent their appearance as a flocculent precipitate in syrup of ipecacuanha; but efficiency is to be sought for as the first desideratum, and hence a menstruum which will extract the activity and make a fluid extract that will not let fall a bulky precipitate of inert matter has been secured; usually this will not mix with syrup without some precipitation, but the improved official process for syrup of ipecacuanha should effectually separate any precipitate resulting from the presence of apotheme in the fluid extract.* The British liquid extract (1898) is a new preparation and is standardized; the excellent researches of Paul and Cownley on ipecac, and the assay work of Kremel, Keller, and others, undoubtedly prompted the introduction of the process for the liquid extract. (See *Ipecacuanha.*) It will probably be found, however, that the U. S. menstruum is preferable. An *acetic extract of ipecacuanha* (*dry*) is used in Great Britain; it has been shown that the heating necessary to dry it is injurious to its emetic properties. (*P. J. Tr.*, 1895, 158.)

This fluid extract is a thin, dark reddish-brown, transparent liquid, of a bitterish slightly acrid taste, but without the nauseous flavor of the root. The emetic dose would be from fifteen to thirty minims (0·9–1·9 C.c.). It is a convenient preparation for adding to expectorant and diaphoretic mixtures, and is used officially principally in preparing the syrup of ipecacuanha.†

EXTRACTUM IRIDIS. U. S. Extract of Iris.

(ĘX-TRĂC'TUM Ī'RĮ-DĬS.)

Extrait d'Iris varié, *Fr.;* Verschiedenfarbige Schwertlilie-Extrakt, *G.*

"Iris, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity.* Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Iris is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

This is an extract which has been introduced to afford an opportunity of using blue flag in the pilular form. The drug appears to us to be too seldom used to merit this distinction. The dose is from one to two grains (0·065–0·13 Gm.).

EXTRACTUM IRIDIS FLUIDUM. U. S. Fluid Extract of Iris.

(ĘX-TRĂC'TUM Ī'RĮ-DĬS FLŪ'Į-DŬM.)

Fluid Extract of Blue Flag; Extrait liquide d'Iris varié, *Fr.;* Flüssiges Verschiedenfarbige Schwertlilie-Extrakt, *G.*

"Iris, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Iris is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, on a water-bath, to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

* R. Rother recommends alcohol for a menstruum and the use of magnesia, and the percolation of the finely-powdered ipecac upon what he calls the disc principle. (*Drug. Circ.*, 1886, p. 4.)

† For discussion of the alkaloidal strength of ipecac and its fluid extract, by H. W. Snow, see *Pharm. Era*, 1887.

The menstruum used in this fluid extract is practically the same as that employed in exhausting blue flag in making the extract, and it will no doubt make a representative preparation. The dose is from five to ten minims (0·3–0·6 C.c.).

EXTRACTUM JALAPÆ. U. S., Br. Extract of Jalap.

(ĘX-TRĂC'TŲM JĄ-LĀ'PÆ.)

Extrait de Jalap, *Fr.;* Jalapen-Extrakt, *G.*

"Jalap, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity.* Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Jalap is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, add the residue to the reserved portion, and evaporate to a pilular consistence." *U. S.*

"Jalap, in coarse powder, 1 *pound* (Imperial) or 1000 grammes; Alcohol (90 per cent.), 4 *pints* (Imp. meas.) or 5 litres; Distilled Water, 1 *gallon* (Imp. meas.) or 10 litres. Macerate the powdered Jalap in the Alcohol for seven days; press out the tincture, filter, and then remove the alcohol by distillation, leaving a soft extract. Again macerate the residue of the Jalap in the water for four hours; express; strain through flannel; evaporate to the consistence of a soft extract. Mix the two extracts, and evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of a firm extract." *Br.*

This extract was introduced into the U. S. Pharmacopœia of 1890, and is intended to replace the abstract formerly official. It will be observed that the U. S. 1890 extract is simply an alcoholic extract, differing from the extract official in 1870, and also from the present British extract, in containing *no aqueous extract* whatever.

Jalap contains a considerable quantity of starch, which is extracted by decoction, but left behind by cold water; and, as this principle serves only to impede the filtration or straining, and to augment the bulk of the extract, without adding to its virtues, cold water is very properly used in the process, if water is used at all. The use both of alcohol and of water was formerly deemed necessary, in order to extract all the medicinal qualities of the drug; and they were employed successively, under the impression that the previous removal of the resin by the former facilitates the action of the latter; but Mr. A. B. Taylor satisfactorily determined that the substance which water will extract from jalap previously exhausted by alcohol has no observable influence on the system, he having taken 240 grains of the matter thus extracted without effect. (*Proc. A. P. A.*, 1864, p. 215.) It was shown, moreover, that the aqueous extract of jalap is hygroscopic, and that it is the cause of the inconvenient hardening of the powdered extract. The substitution of dried sugar of milk for the inert, hygroscopic, aqueous extract was certainly an improvement (see *Abstractum Jalapæ*); but the use of alcohol alone as a menstruum in the U. S. 1890 process will make a stronger preparation, and thus a smaller pill can be made in all cases where extract of jalap is prescribed. According to Cadet de Gassicourt, water at ordinary temperatures, and in the old mode, acts so slowly that fermentation takes place before the active matter is all dissolved. Hence, if the extract be prepared without percolation, the residuum, after the tincture has been decanted, should be digested with water at a heat of about 90° or 100° F., which, while it is insufficient for the solution of the starch, enables the solvent to take up the active matter with sufficient rapidity.

One cwt. of jalap affords, according to Mr. Brande, about fifty pounds of aqueous extract and fifteen of resin. The product of the former is somewhat less by infusion than by decoction; and the extract is proportionately stronger. There is reason to believe, as we have been informed on good authority, that what is sold for extract of jalap is sometimes prepared from tubers which have been previously exhausted of their resin by alcohol; and a spurious substance has been offered in considerable quantities in our markets for extract of jalap, which Messrs. Chas. Bullock and Prof. Parrish proved to owe its purgative property to 42 per cent. of gamboge. (*A. J. P.*, 1862, p. 113.)

Extract of jalap is of a dark-brown color, slightly translucent at the edges, and tenacious when not perfectly dry. It contains the resin and gummy extractive, and, consequently, has all the medical properties of the root; but it is not often exhibited alone, being chiefly used as

an ingredient of purgative pills, for which it is adapted by its comparatively small bulk. It is most conveniently kept for use in the form of powder, which, however, is apt to attract moisture and to aggregate into a solid mass, unless carefully excluded from the air. The dose is from two to eight grains (0·13–0·5 Gm.).*

EXTRACTUM JUGLANDIS. U. S. Extract of Juglans.

(ĘX-TRĂC'TUM JŲG-LĂN'DIS.)

Extrait d'Ecorce de Noyer gris, *Fr.;* Butternussrinden-Extrakt, *G.;* Extract of Butternut.

"Juglans, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or the Juglans is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

This extract was formerly for the most part prepared by the country-people, who are said to have used the bark of the branches, and even the branches themselves, instead of the inner bark of the root, and to have injured the preparation by too much heat. That it should have proved uncertain in the hands of many physicians is, therefore, not a matter of surprise. It should be prepared by the apothecary, and from the inner bark of the root gathered in May or June. Experiments made by B. F. Moise (*A. J. P.*, 1881, p. 153) prove that alcohol and diluted alcohol are better menstrua than water for the bark. Prof. Procter found an extract of the fresh bark prepared with diluted alcohol to have much more of the pungency of the bark than the official; on account of these results, the process for the extract was changed at the 1880 revision, and diluted alcohol substituted for water as a menstruum, with marked improvement. The extract of butternut is of a black color, a sweetish odor, and a bitter astringent taste. In the dose of from five to ten grains (0·33–0·65 Gm.) it acts as a mild cathartic, whilst in larger doses it is an active purge.

EXTRACTUM KRAMERIÆ. U. S., Br. Extract of Krameria.

(ĘX-TRĂC'TUM KRĄ-MĒ'RI-Æ.)

Extract of Rhatany; Extractum Ratanhæ, *P. G.;* Extrait de Ratanhia, *Fr.;* Ratanha-Extrakt, *G.*

"Krameria, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *a sufficient quantity*. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, pack it in a conical glass percolator, and gradually pour Water upon it, until the infusion passes but slightly imbued with the astringency of the Krameria. Heat the liquid to the boiling point, strain, and evaporate the strained liquid, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to dryness." *U. S.*

"Macerate coarsely powdered Krameria Root in twice its weight of Distilled Water for twenty-four hours; pack in a percolator; and percolate with more Distilled Water until the Krameria Root is exhausted. Evaporate the liquid to dryness." *Br.*

In selecting a plan for the preparation of this extract, it was undoubtedly wise to adopt percolation, with cold water as the menstruum. It is absolutely necessary to the success of the process that the root should be well and uniformly comminuted; and the "No. 40 powder" of the U. S. Pharmacopœia is, therefore, preferable to the "coarse powder" of the British. The wood of the root yielded to Prof. Procter only 6·8 per cent. of extract, while the bark separated from the wood yielded 33 per cent. As the wood is of difficult pulverization, the inference is obvious that, in powdering the roots, the ligneous portion may be rejected with advantage. (*A. J. P.*, xiv. 270.) As a prolonged exposure of the infusion to the air is attended

* *Fluid Extract of Jalap.* The following process has been proposed by Prof. Procter. Take of jalap, in coarse powder, ℥xvi; sugar, ℥viij; potassium carbonate, ℥ss; alcohol, water, each, *q. s.* Add to the jalap one pint of a mixture consisting of two parts of alcohol and one of water, and set aside for twenty-four hours. Then put the mixture into a percolator, and pour on it diluted alcohol until half a gallon has passed. Evaporate the filtered liquid one-half, add the sugar and potassium carbonate, and evaporate to 12 fluidounces. Put the liquid, while warm, into a pint bottle, add four fluidounces of alcohol, and mix. The potassium carbonate renders the resin soluble in water, and probably favorably qualifies the irritating properties of the jalap. A fluidrachm of this extract would represent a drachm of jalap, so that the dose should be from 15 to 30 minims (0·9–1·9 C.c.). (*A. J. P.*, xxix. 108.)

with the absorption of oxygen and the production of insoluble apotheme, it is desirable that the evaporation should be conducted rapidly, or in a vacuum. There scarcely appears to be occasion, in the case of rhatany, for heating and filtering the infusion before evaporation, the only use of which is to get rid of albumen, which is not among the recognized ingredients of the root.

Very inferior extracts of rhatany are often sold. Such is the South American extract, which has been occasionally imported. As the product obtained by decoction is greater than that afforded by the official plan, the temptation to substitute the former is not always resisted, although it has been shown to contain nearly 50 per cent. of insoluble matter. Some druggists prepare the extract with an alcoholic menstruum, with a view to the greater product; but the extract thus prepared has from 20 to 30 per cent. less of the active principle than the official. A substance has been shown to us, said to have been imported as extract of rhatany from Europe, which was nearly tasteless, and was plausibly conjectured to be the dried coagulated matter of old tincture of kino.

Extract of rhatany should have a reddish-brown color, a smooth shining fracture, and a very astringent taste, and should be almost entirely soluble in water. Its virtues may be considered as in proportion to its solubility. It is much used for all the purposes for which the astringent extracts are employed. The dose is from ten to twenty grains (0·65–1·3 Gm.).

EXTRACTUM KRAMERIÆ FLUIDUM. U. S. Fluid Extract of Krameria.

(ĘX-TRĂC'TUM KRĄ-MĒ'RĮ-Æ FLŪ'Į-DŬM.)

Extrait liquide de Ratanhia, *Fr.;* **Flüssiges Ratanha-Extrakt,** *G.*

"Krameria, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of Diluted Alcohol, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Krameria is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This process does not differ essentially from that formerly official; the fluid extract well represents the root, and is of a deep-red color and a very astringent taste. The dose is from ten minims to a fluidrachm (0·6–3·75 C.c.).

EXTRACTUM LAPPÆ FLUIDUM. U. S. Fluid Extract of Lappa.

(ĘX-TRĂC'TUM LĂP'PÆ FLŪ'Į-DŬM.)

"Lappa, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Lappa is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract of burdock: it is of a dark brownish-red color. Dose, from thirty to sixty minims (1·87–3·75 C.c.), well diluted.

EXTRACTUM LEPTANDRÆ. U. S. Extract of Leptandra.

(ĘX-TRĂC'TŲM LĘP-TĂN'DRÆ.)

Extract of Culver's Root; Extrait de Leptandra, *Fr.;* **Leptandrawurzel-Extrakt,** *G.*

"Leptandra, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Leptandra is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

This extract will furnish practitioners who have been in the habit of prescribing the so-called *leptandrin*, with a uniform preparation. Dose, from five to ten grains (0·33–0·65 Gm.).

EXTRACTUM LEPTANDRÆ FLUIDUM. U. S. Fluid Extract of Leptandra.

(ĘX-TRĂC'TŲM LĘP-TĂN'DRÆ FLŪ'Į-DŬM.)

Fluid Extract of Culver's Root; Extrait liquide de Leptandra, *Fr.;* **Flüssiges Leptandra-Extrakt,** *G.*

"Leptandra, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Leptandra is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract of a reddish-brown color, and is given in the dose of from twenty minims to a fluidrachm (1·25–3·75 C.c.).

EXTRACTUM LOBELIÆ FLUIDUM. U. S. Fluid Extract of Lobelia.

(ĘX-TRĂC'TŲM LŌ-BĒ'LĮ-Æ FLŪ'Į-DŬM.)

Extrait liquide de Lobélie enflée, *Fr.;* **Flüssiges Lobelienkraut-Extrakt,** *G.*

"Lobelia, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Lobelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a valuable fluid extract. It is of a dark olive color, having the acrid taste of lobelia very marked. The dose as an expectorant is from one to five minims (0·06–0·3 C.c.); as an emetic, from ten to twenty minims (0·6–1·25 C.c.).

EXTRACTUM LUPULINI FLUIDUM. U. S. Fluid Extract of Lupulin.

(ĘX-TRĂC'TUM LŪ-PŬ-LĪ'NĪ FLŪ'Į-DŬM.)

Extrait liquide de Lupuline, *Fr.;* Flüssiges Lupulin-Extrakt, *G.*

"Lupulin, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the Lupulin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the Lupulin and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Lupulin is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." U. S.

This fluid extract is of a very dark brown color, having the odor and taste of hops very distinctly. Owing to its resinous character, it is not miscible with aqueous liquids, and if desired in combination it is necessary to use gum arabic or other emulsifying agent. The dose is from ten to fifteen minims (0·6–0·9 C.c.).

EXTRACTUM MATICO FLUIDUM. U. S. Fluid Extract of Matico.

(ĘX-TRĂC'TUM MĂT'Į-CŌ FLŪ'Į-DŬM.)

Extrait liquide de Matico, *Fr.;* Flüssiges Matico-Extrakt, *G.*

"Matico, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Matico is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is probably the best liquid preparation of matico: the present formula does not differ materially from that of 1870. It is a greenish-black liquid, which probably contains all of the virtues of matico, and affords an excellent form for internal administration. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM MENISPERMI FLUIDUM. U. S. Fluid Extract of Menispermum.

(ĘX-TRĂC'TUM MĔN-Į-SPĔR'MĪ FLŪ'Į-DŬM.)

"Menispermum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Menispermum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract, the introduction of which is of doubtful utility: the drug is unreliable in its effects, and is rarely used. Dose, from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM MEZEREI FLUIDUM. U. S. Fluid Extract of Mezereum.

(ĘX-TRĂC'TUM MĘ-ZĒ'RĘ-Ī FLŪ'Į-DŬM.)

Extrait liquide de Mézéréon (de Garou), *Fr.;* Flüssiges Seidelbast-Extrakt, *G.*

"Mezereum, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Mezereum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is identical with that formerly official. It is too acrid for internal administration: its principal use is as the active ingredient in the stimulating ointment of mezereon.

EXTRACTUM NUCIS VOMICÆ. U. S., Br. Extract of Nux Vomica.

(ĘX-TRĂC'TUM NŪ'CĬS VŎM'Į-CÆ.)

"An Extract containing 5 per cent. of Strychnine." *Br.*

Extractum Strychni Spirituosum, *P. G.;* Extractum Nucum Vomicarum Spirituosum (vel Alcoholicum); Extrait de Noix-Vomique, *Fr.;* Weingeistiges Krähenaugen-Extrakt, *G.*

"Nux Vomica, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, Ether, Sugar of Milk, recently dried and in fine powder, each, *a sufficient quantity.* Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Mix the powder with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of the mixture, to which the Acetic Acid had previously been added, and let it macerate, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it tightly in a cylindrical glass percolator, gradually pour menstruum upon it, and continue the percolation, until the Nux Vomica is practically exhausted. Distil off the Alcohol by means of a water-bath, transfer the remainder to a tared capsule, and evaporate it until it weighs about *one hundred and fifty grammes* [or 5 ounces av., 127 grains]. Transfer it to a bottle of the capacity of about *five hundred cubic centimeters* [or about 1 pint], and wash the capsule with about *fifty cubic centimeters* [or 1 fluidounce, 331 minims] of warm Water, adding the washings to the bottle and mixing the contents thoroughly. When the liquid extract is cold, add to it *one-fourth* of its volume of Ether, stopper the bottle, and bring the extract and Ether into intimate contact by gently agitating and frequently inverting the bottle, avoiding violent shaking so as to prevent the formation of an emulsion. Pour off the ethereal layer as closely as possible, and repeat this treatment with Ether several times, until a few drops of the ethereal layer no longer impart a permanent, greasy stain to filtering paper. Then transfer the contents of the bottle back to the tared capsule, using a sufficient quantity of warm Water for washing. Recover the Ether from the united ethereal washings, add to the oily residue about *fifteen cubic centimeters* [or about 4 fluidrachms] of boiling Water, and then Acetic Acid, in drops, until the mixture has a permanent acid reaction. Then filter it through a moistened filter, and wash the filter with a little Water. Add the filtrate to the extract in the capsule, evaporate until the residue weighs about *two hundred grammes* [or 7 ounces av., 24 grains], and allow it to become cold. Then determine its weight exactly, remove *four grammes* [or 61·728 grains] of the mass, and assay this by the process given below, using the amounts of liquids there directed for *two grammes* [or 30·864 grains] of dry extract. In another portion of *five grammes* [or 77·16 grains] determine the amount of water by drying it, in a flat-bottomed capsule, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained ascertain, by calculation, the amount of total alkaloids and of water contained in the

remainder of the mass, add to this enough well-dried Sugar of Milk to bring the quantity of alkaloids in the final dry extract to *fifteen per cent.*, then evaporate the mass to complete dryness, reduce it to powder, and transfer it to small, well-stoppered vials." *U. S.*

Extract of Nux Vomica, when assayed by the following process, should be found to contain 15 per cent. of total alkaloids.

Assay of Extract of Nux Vomica. U. S. 1890. "Extract of Nux Vomica, dried at 100° C. (212° F.), *two grammes;* Alcohol, Ammonia Water, Water, Chloroform, Sulphuric Acid decinormal volumetric solution, Potassium Hydrate centinormal volumetric solution, each, *a sufficient quantity.* Put 2 Gm. of the dried Extract of Nux Vomica into a glass separator, add to it 20 C.c. of a previously prepared mixture of 2 volumes of alcohol, 1 volume of ammonia water (specific gravity 0·960), and 1 volume of water, and shake the well-stoppered separator until the extract is dissolved. Then add 20 C.c. of chloroform and agitate during five minutes. Allow the chloroform to separate, remove it as far as possible, pour into the separator a few C.c. of chloroform, and, without shaking, draw this off through the stopcock to wash the outlet tube. Repeat the extraction with two further portions of chloroform of 15 C.c. each, and wash the outlet-tube each time as just directed. Collect all the chloroformic solutions in a wide beaker, expose the latter to a gentle heat, on a water-bath, until the chloroform and ammonia are completely dissipated, add to the residue 10 C.c. of sulphuric acid decinormal volumetric solution measured with great care from a burette, stir gently, and then add 20 C.c. of hot water. When solution has taken place, add 2 C.c. of Brazil wood test-solution, and then carefully run in potassium hydrate centinormal volumetric solution, until a permanent pinkish color is produced by the action of a slight excess of alkali upon the Brazil wood indicator. Divide the number of C.c. of potassium hydrate centinormal volumetric solution used by 10, subtract the number found from 10 (the 10 C.c. of acid decinormal volumetric solution used), multiply the remainder by 0·0364 and that product by 50 (or, multiply at once by 1·82), which will give the percentage of *total alkaloids* in the Extract of Nux Vomica, it being assumed that strychnine and brucine are present in equal proportion, and the above factor being found by taking the mean of their respective molecular weights rounded off to whole numbers [(334 + 394) ÷ 2 = 364]."

"Liquid Extract of Nux Vomica, 11 *fl. ounces* (Imperial measure) or 550 cubic centimetres; Milk Sugar, in fine powder, *a sufficient quantity.* Ascertain the proportion of Milk Sugar required for *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract by the following experiment on *one fluid ounce* (Imp. meas.) or fifty cubic centimetres.

"Evaporate *one fluid ounce* (Imp. meas.) or fifty cubic centimetres of the Liquid Extract of Nux Vomica in a counterpoised dish on a water-bath to a moderately firm extract, and weigh. The difference between the weight of the extract and *one hundred and thirty-one and a quarter grains* (Imp.) or fifteen grammes, multiplied by ten, will give the amount of Milk Sugar required for the remaining *ten ounces* (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract of Nux Vomica.

"Distil the alcohol from *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Liquid Extract of Nux Vomica; to the residue add the quantity of Milk Sugar shown to be required by the above experiment; mix; evaporate to the consistence of a firm extract, which should weigh *three ounces* (Imp.) or one hundred and fifty grammes." *Br.*

For the first time in its history (1893) the U. S. Pharmacopœia contains an assay process for extract of nux vomica, the demand for greater precision in pharmaceutical preparations being the motive which led the Committee of Revision to adopt this process. The fixed oil found in the drug (see *Nux Vomica*) is removed by the use of ether, and the alkaloids which are taken up by the fixed oil during the percolation of the drug are washed out with boiling water acidulated with acetic acid in excess; this solution is filtered and added to the partially evaporated extract, and the whole is then ready for the assay. The menstruum adopted for the extract is one which was found by abundant trial best fitted for exhausting the drug, and the previous digestion for forty-eight hours in contact with acetic acid materially aids in softening the very tough tissues which envelop the active principles. The process of assay was simplified to as great an extent as was possible without sacrificing accuracy, and consists in first dissolving the extract and then thoroughly extracting the alkaloids by destroying their natural combination with igasuric acid, by means of ammonia, and taking up the liberated alkaloids with chloroform; the latter is removed by evaporation, and the residue dissolved in hot water containing an accurately measured quantity of sulphuric acid. The liquid is then made slightly alkaline after the addition of Brazil-wood indicator, and the number of cubic centimeters of

potassium hydrate volumetric solution required to effect this furnishes the data for the calculation which gives the percentage of total alkaloids present.

The process of the Br. Pharm. directs the evaporation of the standardized liquid extract (see next article) and the addition of sufficient sugar of milk to the residue to make the extract contain 5 per cent. of strychnine. The finished product "has about two-thirds the total alkaloidal strength of the Extract of Nux Vomica of the Br. Pharm. of 1885." *Br.*

In both the U. S. and Br. Pharmacopœias the nux vomica is directed in fine powder. When the extract is kept in powder, it is apt to agglutinate into a tough mass. According to Zippel, this may be prevented by adding a little water before the close of the evaporation, and then continuing the evaporation to dryness. M. Recluz obtained from sixteen ounces of nux vomica the average product of one ounce and a quarter. (See *Proc. A. P. A.*, 1894, 551, 643; *P. J. Tr.*, 1894, 137.) Dose, a quarter of a grain (0·016 Gm.), equivalent to about $\frac{1}{27}$ of a grain of total alkaloids.

EXTRACTUM NUCIS VOMICÆ FLUIDUM. U. S. (Br.) Fluid Extract of Nux Vomica.

(ĘX-TRĂC'TUM NŪ'CĬS VŎM'Į-ÇÆ FLŪ'Į-DŬM.)

"A Liquid Extract containing 1½ grains of Strychnine in 110 minims (1·5 grammes in 100 cubic centimetres)." *Br.*

Extractum Nucis Vomicæ Liquidum, *Br.*, Liquid Extract of Nux Vomica; Extrait liquide de Noix-Vomique, *Fr.*; Flüssiges Krähenaugen-Extrakt, *G.*

"Nux Vomica, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity*. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol, and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *one thousand cubic centimeters* [or 33 fluidounces, 6¼ fluidrachms] of the mixture, to which the Acetic Acid had previously been added, and let it digest, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it in a cylindrical glass percolator, and gradually pour menstruum upon it, until the Nux Vomica is practically exhausted. Distil off the Alcohol by means of a water-bath, transfer the remainder to a tared capsule, evaporate it until it weighs about *two hundred grammes* [or 7 ounces av., 24 grains], and allow it to become cold. Then determine the weight exactly, remove *four grammes* [or 61·728 grains] of the mass, and assay this by the process given under Extract of Nux Vomica (see *Extractum Nucis Vomicæ*), using the amounts of liquids there directed for *two grammes* [or 30·864 grains] of dry extract. From the results thus obtained ascertain, by calculation, the amount of total alkaloids in the remainder of the mass, and then add to the latter, first, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and afterwards a sufficient quantity of a mixture of *three volumes* of Alcohol and *one volume* of Water, so that each *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of the finished fluid extract shall contain *one and five-tenths grammes* [or 23·148 grains] of total alkaloids." *U. S.*

"Moisten *one pound* (Imperial) or five hundred grammes of Nux Vomica, in No. 20 powder, with *eight fluid ounces* (Imp. meas.) or two hundred and fifty cubic centimetres of Alcohol (70 per cent.); set aside in a covered vessel for six hours; pack firmly in a percolator; pour over the powder sufficient of the menstruum to saturate it and to leave a stratum above it; when the liquid begins to flow, close the lower orifice; set aside for twenty-four hours; continue slow percolation, adding more menstruum as required, until *twelve fluid ounces* (Imp. meas.) or three hundred and seventy-five cubic centimetres have been collected; reserve this strong percolate. Change the receiver; continue the percolation until about *sixty fluid ounces* (Imp. meas.) or eighteen hundred and seventy-five cubic centimetres of the menstruum have been employed, or until the powder is exhausted; press the marc; add the expressed liquid to the weaker percolate; remove the alcohol by distillation; evaporate the residue to *one fluid ounce* (Imp. meas.) or thirty-one cubic centimetres; add *three fluid ounces* (Imp. meas.) or ninety-three cubic centimetres of Alcohol (90 per cent.). Add this mixture to the reserved portion; set aside for twenty-four hours; pour off the clear liquid; filter the remainder.

"Determine the proportion of Strychnine in the resulting strong liquid extract by the following analytical process:

"Evaporate 10 cubic centimetres to a thick syrupy consistence on a water-bath; dissolve the residue in 20 cubic centimetres of *water*, heating if necessary; place the solution in a

separator, and add 5 grammes of *sodium carbonate* dissolved in 25 cubic centimetres of *water*, together with 10 cubic centimetres of *chloroform;* agitate thoroughly; set aside; separate the clear chloroformic solution. Twice repeat the agitation with *chloroform*, and the separation. Mix 6 cubic centimetres of *diluted sulphuric acid* with 25 cubic centimetres of *water;* divide this into three parts, and shake the mixed chloroformic solutions with each in turn. Dilute the united acid liquids with *water* to 175 cubic centimetres; transfer to a stoppered flask, adding 25 cubic centimetres of *solution of potassium ferrocyanide;* shake well and frequently during half an hour; allow to stand for 6 hours. Transfer the precipitate to a small filter, rinsing out the last portions with *water* containing one-fortieth of its volume of *diluted sulphuric acid*, and wash until the washings are free from bitterness. Rinse the precipitate into a separator. Add 5 cubic centimetres of *solution of ammonia*, and shake well; then add 15 cubic centimetres of *chloroform* in two successive portions, shaking well after each addition; separate the chloroformic solutions, mix and allow the *chloroform* to evaporate in a counterpoised dish in a current of warm air; dry the residue for 1 hour on a water-bath, covering the dish to avoid loss of Strychnine from decrepitation; weigh.

"From this weight calculate the amount of Strychnine in the strong liquid extract, and add to the latter sufficient Alcohol (70 per cent.) to produce a Liquid Extract of Nux Vomica containing 1·5 grammes of Strychnine in 100 cubic centimetres, or 1½ grains in 110 minims." *Br.*

This fluid extract has been retained principally with the view of giving the pharmacist an accurately adjusted liquid preparation of nux vomica which is more concentrated than the tincture. The process of assay is the same as that for the extract; and most pharmacists will prefer to keep this assayed fluid extract and dilute it to the proper degree to make the tincture: the usual objection to this method of making tinctures does not apply here, as the liquid used as the basis has been accurately adjusted to a definite strength. The British assay process is based on that recommended by Profs. Dunstan and Short (*P. J. Tr.*, 1884, 623). The menstruum has been carefully selected so that the alkaloids shall be extracted and as much of the oil left in the residue as possible. In order to make a dry powdered extract it would be necessary to separate the fixed oil before assaying it, and then to make up the weight, if necessary, with sugar of milk or some inert, soluble powder. An important advantage, aside from that of securing uniformity and safety, is that the operator need not carry the percolation beyond the point at which it ceases to be profitable (on account of the waste of alcohol), because the extract must be brought to a definite alkaloidal strength. Such an extract can be used with great advantage to make tincture of nux vomica of definite alkaloidal strength. For Beckurts's method of assaying nux vomica, see *Pharm. Era*, 1887, 447. The dose is three minims (0·18 C.c.), equivalent to about $\frac{1}{2\frac{1}{3}}$ of a grain of total alkaloids.

EXTRACTUM OPII. U. S., Br. Extract of Opium.

(ĘX-TRĂC'TŬM Ō'PĮ-Ī.)

"An extract containing 20 per cent. of morphine." *Br.*

Extrait d'Opium, Extrait thébaïque, *Fr.;* Opiumextrakt, *G.*

"Powdered Opium, *one hundred grammes* [or 3 ounces av., 231 grains]; Sugar of Milk, recently dried and in fine powder, Water, each, *a sufficient quantity.* Triturate the Powdered Opium in a mortar thoroughly with *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water, repeat the trituration occasionally, in the course of twelve hours, then filter through a rapidly-acting, double filter, and wash the filter and residue with Water, until the filtrate is nearly colorless. Concentrate the filtrate and washings in a tared capsule, on a water-bath, until the residue weighs about *two hundred grammes* [or 7 ounces av., 24 grains], and allow it to become cold. Then determine the weight exactly, transfer *twelve grammes* [or 185·18 grains] of it to an Erlenmeyer flask having a capacity of about *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], and determine in this portion the amount of morphine by the process of assay given below, using the quantities of liquids there directed for *four grammes* [or 61·728 grains] of the dry extract. In another portion of *five grammes* [or 77·16 grains] determine the amount of water by drying it in a flat-bottomed capsule, at 100° C. (212° F.), until it ceases to lose weight. From the results thus obtained ascertain, by calculation, the amount of morphine and of water contained in the remainder of the extract, add to this enough well-dried Sugar of Milk to bring the quantity of morphine in the final dry extract to

eighteen per cent., then evaporate the whole to dryness, reduce it to powder, and transfer it to small, well-stoppered vials." *U. S.*

"Opium, sliced, 1 *pound* (Imperial) or 1000 grammes; Distilled Water, 6 *pints* (Imp. meas.) or 7½ litres. Set aside the sliced Opium with one-third of the Distilled Water for twenty-four hours; express the liquid; thoroughly mix the residue of the Opium with another third of the Distilled Water; set aside for twenty-four hours; express; repeat the operation with the remaining third of the Distilled Water; mix the liquids; strain through flannel; evaporate to about *half a pound* (Imp.) or five hundred grammes.

"*Test.*—Analyzed as described under 'Opium,' using 7 grammes of the Extract in place of the 14 grammes of Opium, this Extract should yield 20 per cent. of morphine. To obtain Extract of Opium of proper strength and consistence, stronger and weaker extracts may be mixed, and stronger extracts may be diluted with Distilled Water or with Milk Sugar as may be necessary." *Br.*

Assay of Extract of Opium. U. S. "Extract of Opium, dried at 100° C. (212° F.), *four grammes;* Ammonia Water, *two and two-tenths cubic centimeters;* Alcohol, Ether, Water, each, *a sufficient quantity.* Dissolve the Extract of Opium in 30 C.c. of water, filter the solution through a small filter, and wash the filter and residue with water, until all soluble matters are extracted, collecting the washings separately. Evaporate, in a tared capsule, first, the washings to a small volume, then add the first filtrate, and evaporate the whole to a weight of 10 Gm. Rotate the concentrated solution about in the capsule until the rings of extract are redissolved, pour the liquid into a tared Erlenmeyer flask having a capacity of about 100 C.c., and rinse the capsule with a few drops of water at a time, until the entire solution weighs 15 Gm. Then add 7 Gm. (or 8·5 C.c.) of alcohol, shake well, add 20 C.c. of ether, and shake again. Now add the ammonia water from a graduated pipette or burette, stopper the flask with a sound cork, shake it thoroughly during ten minutes, and then set it aside, in a moderately cool place, for at least six hours, or over night. Remove the stopper carefully, and, should any crystals adhere to it, brush them into the flask. Place in a small funnel two rapidly-acting filters, of a diameter of 7 Cm., plainly folded, one within the other (the triple fold of the inner filter being laid against the single side of the outer filter), wet them well with ether, and decant the ethereal solution as completely as possible upon the inner filter. Add 10 C.c. of ether to the contents of the flask, rotate it, and again decant the ethereal layer upon the inner filter. Repeat this operation with another portion of 10 C.c. of ether. Then pour into the filter the liquid in the flask, in portions, in such a way as to transfer the greater portion of the crystals to the filter, and, when this has passed through, transfer the remaining crystals to the filter by washing the flask with several portions of water, using not more than about 10 C.c. in all. Allow the double filter to drain, then apply water to the crystals, drop by drop, until they are practically free from mother-water, and afterwards wash them, drop by drop, from a pipette, with alcohol previously saturated with powdered morphine. When this has passed through, displace the remaining alcohol by ether, using about 10 C.c., or more if necessary. Allow the filter to dry in a moderately warm place, at a temperature not exceeding 60° C. (140° F.), until its weight remains constant, then carefully transfer the crystals to a tared watch-glass and weigh them. The weight found, multiplied by 25, represents the amount of crystallized morphine obtained from 100 Gm. of the Extract."

The process for the U. S. extract differs from that formerly official in several particulars, powdered opium being used instead of opium, and, notwithstanding that the powdered opium is standardized, the extract is assayed, and the quantity of morphine adjusted to 18 per cent., so that the extract of opium can now be depended upon to contain twice as much morphine as opium of the minimum official strength.

The U. S. P. 1890 process is a great improvement over those formerly official: in addition to the definite strength of the extract, its reduction to a pulverulent form will enable the pharmacist to dispense it more accurately and conveniently.

As purely aqueous preparations of opium have been found to agree better with certain individuals than opium alone or its alcoholic preparations, there is reason to believe that there are in the crude drug one or more principles, capable of causing nausea, headache, nervous disturbance, etc., which are insoluble in water, though extracted by alcohol or ether. (See *Opium Deodoratum.*) The dose of the American extract, about equivalent to one grain of dried opium, is three-quarters of a grain (0·05 Gm.). The British extract has the official dose of from one-quarter to one grain (0·016–0·06 Gm.).

EXTRACTUM OPII LIQUIDUM. Br. Liquid Extract of Opium.

(ĘX-TRĂC'TUM Ō'PI-Ī LĬQ'UI-DŬM—ĭk'wę-dŭm.)

"A Liquid Extract containing ¾ grain of morphine in 110 minims (0·75 gramme in 100 cubic centimetres.)" *Br.*

Extrait liquide d'Opium, *Fr.;* Flüssiges Opiumextrakt, *G.*

"Extract of Opium, ¾ *ounce* (Imperial) or 18·75 grammes; Distilled Water, 16 *fl. ounces* (Imp. meas.) or 400 cubic centimetres; Alcohol (90 per cent.), 4 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Mix the Extract of Opium with the Distilled Water; set aside for an hour, stirring frequently; add the Alcohol; set aside in a cool place for twenty-four hours; filter. The product should measure *one pint* (Imp. meas.) or five hundred cubic centimetres. Specific gravity from 0·985 to 0·995.

"*Test.*—Analyzed as described under 'Tinctura Opii,' this Liquid Extract should yield an amount of morphine, reckoned as anhydrous, corresponding to not less than 0·7 gramme nor more than 0·8 gramme in 100 cubic centimetres. Each fluid ounce of Liquid Extract of Opium represents 16½ grains of Extract of Opium; 20 cubic centimetres represent 0·75 gramme." *Br.*

In the last revision of the British Pharmacopœia this preparation was reduced in morphine strength 25 per cent.

It is a good preparation, one which has long been needed, and in the absence of which from the Pharmacopœia empirical preparations have obtained a certain vogue. It is well known that in opium there are principles soluble in alcohol but not in water, which often produce various disagreeable effects not experienced from the aqueous extract. What was wanted was a liquid preparation meeting this demand. All that was required was to make an aqueous solution of this extract, and to add something to preserve it. The British Pharmacopœia uses alcohol for the purpose, and in the original formula employed it in such proportion that an Imperial pint of the liquid should contain three fluidounces of the spirit, or between one-sixth and one-seventh by measure. But this amount of alcohol, according to Mr. Squire, is insufficient for its preservation, and should be doubled. In the present Pharmacopœia the spirit has been increased to four fluidounces, and the water diminished from seventeen to sixteen fluidounces; but even with this increase the spirit constitutes only one-fifth, which is considerably short of the proportion recommended by Mr. Squire. A preparation similar to the British was made some years since by Mr. Eugene Dupuy, of New York. (See *Opium.*) In the *Deodorized Tincture of Opium* of the U. S. Pharmacopœia the advantages of the preparation have, we think, been still better secured. The dose of the liquid extract, equivalent to a grain of opium, would be about fifteen minims (0·9 C.c.).

EXTRACTUM PAREIRÆ FLUIDUM. U. S. (Br.) Fluid Extract of Pareira.

(ĘX-TRĂC'TUM PA-REI'RÆ FLŪ'I-DŬM.)

Extractum Pareiræ Liquidum, *Br.;* Liquid Extract of Pareira; Extrait liquide de Pareira Brava, *Fr.;* Flüssiges Pareira-Extrakt, *G.*

"Pareira, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *seven hundred and twenty cubic centimeters* [or 24 fluidounces, 166 minims] of Alcohol, and *one hundred and eighty cubic centimeters* [or 6 fluidounces, 41 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, until the Pareira is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. *U. S.*

"Add to Pareira Root, in No. 40 powder, rather more than an equal bulk of boiling Distilled Water and set aside for twenty-four hours; then pack in a percolator and pass boiling Distilled Water slowly until the percolate amounts to about ten times the weight of the Pareira Root, or until the latter is exhausted. Ascertain the proportion of extractive matter in the percolate by evaporating a small weighed quantity in a counterpoised dish on a water-bath to a firm consistence, and weighing the product. Then evaporate the bulk of the percolate until the residual liquid contains one-third of its weight of such extractive matter; mix with this residual liquid sufficient Alcohol (90 per cent.) to produce from three volumes of the evaporated liquid four volumes of Liquid Extract of Pareira. Filter, or otherwise clarify, if necessary." *Br.*

The former British preparation was a concentrated solution of the extract, preserved by adding somewhat less than one-fourth of its measure of alcohol. There must be considerable loss through the action of the heat in evaporating the extract, and again through precipitation, due to attempting to dissolve an aqueous extract in a hydro-alcoholic menstruum. The present liquid extract (1898) is made by percolating the powdered root with boiling water; the process does not state how boiling distilled water is to be passed slowly, and the inference is that it is only intended that boiling water should be poured on the drug; no provision is made to prevent rapid cooling; it would probably be best to use a jacketed percolator, the space being filled with steam or hot water, if hot percolation is intended. The American fluid extract is made directly from the drug, with diluted alcohol and glycerin, and is undoubtedly the better preparation. The dose is from one to two fluidrachms (3·75–7·5 C.c.).

EXTRACTUM PHYSOSTIGMATIS. U. S., Br. Extract of Physostigma.

(ĘX-TRĂC'TŲM PHĪ-SŌ-STĬG'MĄ-TĬS.)

Extract of Calabar Bean; Extractum Fabæ Calabaricæ, *P. G.;* Extrait de Fève de Calabar, *Fr.;* Kalabarbohnen-Extrakt, *G.*

"Physostigma, in No. 80 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 3½ fluidrachms] of tincture are obtained, or the Physostigma is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 208 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, on a water-bath, to a pilular consistence." *U. S.*

"Calabar Bean, in No. 40 powder, 1 *pound* (Imperial) or 1000 grammes; Alcohol (90 per cent.), 4 *pints* (Imp. meas.) or 5 litres; Milk Sugar, in fine powder, *a sufficient quantity*. Mix the powdered Calabar Bean with *one pint* (Imp. meas.) or twelve hundred and fifty cubic centimetres of the Alcohol; set aside in a closed vessel for forty-eight hours, agitating occasionally; transfer to a percolator; when the liquid ceases to pass, add the remainder of the Alcohol so that it may slowly percolate through the powder; remove the marc and subject it to pressure; add the expressed liquid to the percolate; filter; recover most of the alcohol by distillation; transfer the residue to a counterpoised basin, and evaporate to the consistence of a very soft extract; weigh; then add three times its weight of Milk Sugar and mix thoroughly to produce a firm Extract. This preparation is one-fourth the strength of the Extract of Calabar Bean of the British Pharmacopœia of 1885." *Br.*

As alcohol is a much better solvent than water of the active principles of the bean, it is preferred in making the extract. Dose, from one-sixteenth to one-sixth of a grain (0·004–0·01 Gm.).

EXTRACTUM PHYTOLACCÆ RADICIS FLUIDUM. U. S. Fluid Extract of Phytolacca Root.

(ĘX-TRĂC'TŲM PHĪ-TŌ-LĂC'ÇÆ RĄ-DĪ'CĬS FLŪ'Į-DŬM.)

"Phytolacca Root, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and,

having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Phytolacca Root is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract. Dose, as an alterative, from one to five minims (0·06–0·3 C.c.); as an emetic, thirty minims (1·8 C.c.).

EXTRACTUM PILOCARPI FLUIDUM. U. S. (Br.) Fluid Extract of Pilocarpus.

(ĘX-TRĂC'TUM PĪ-LO-CĂR'PĪ FLŪ'I-DŬM.)

Extractum Jaborandi Liquidum, *Br.,* Liquid Extract of Jaborandi.

" Pilocarpus, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Pilocarpus is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

" Jaborandi Leaves, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (45 per cent.), *a sufficient quantity*. Moisten the powdered Jaborandi Leaves with *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of the Alcohol; pack the moistened powder in a percolator, and set aside for twelve hours; then percolate with the menstruum, collecting and reserving *seventeen fluid ounces* (Imp. meas.) or eight hundred and fifty cubic centimetres of percolate; continue percolation until an additional quantity of *fifty fluid ounces* (Imp. meas.) or two and a half litres of percolate is obtained; distil the latter so as to recover the alcohol, evaporate the residual aqueous liquid to the consistence of a soft extract, adding it to the reserved percolate; to the product add sufficient of the Alcohol to produce *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres of the Liquid Extract." *Br.*

This preparation represents jaborandi leaves thoroughly. Of the liquid preparations of the drug, the infusion and tincture are both open to objection, the former on account of the bulkiness of the dose, and the latter because of the amount of alcohol it contains. The dose of the fluid extract is from fifteen minims to half a fluidrachm (0·9–1·9 C.c.).

EXTRACTUM PODOPHYLLI. U. S. Extract of Podophyllum.

(ĘX-TRĂC'TUM PŎD-O-PHŸL'LĪ.)

Extrait de Podophylle, *Fr.;* **Fussblattwurzel-Extrakt,** *G.*

" Podophyllum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Podophyllum is exhausted. Distil off the Alcohol from the tincture by means of a water-bath, and evaporate the residue, on a water-bath, to a pilular consistence." *U. S.*

This is possessed of the purgative properties of the root, and may be given in the dose of

from one to three grains (0·06–0·2 Gm.). From experiments made by Mr. John R. Lewis, it is probable that the alcoholic extract would be more powerful as a purgative than the official preparation; but it does not follow that it would be more serviceable. (See *A. J. P.*, xix.)

EXTRACTUM PODOPHYLLI FLUIDUM. U. S. Fluid Extract of Podophyllum.

(ĘX-TRĂC'TUM PŎD-Ǫ-PHĬL'LĪ FLŪ'Į-DŬM.)

Extrait liquide de Podophylle, *Fr.;* Flüssiges Fussblattwurzel-Extrakt, *G.*

"Podophyllum, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Podophyllum is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which well represents the root, but is of very little use. The dose is from five to fifteen minims (0·3–0·9 C.c.).

EXTRACTUM PRUNI VIRGINIANÆ FLUIDUM. U. S. Fluid Extract of Wild Cherry.

(ĘX-TRĂC'TUM PRŪ'NĪ VĬR-ĢĬN-Į-Ā'NÆ FLŪ'Į-DŬM.)

Extrait liquide de Cerisier de Virginie, *Fr.;* Flüssiges Wildkirschenrinden-Extrakt, *G.*

"Wild Cherry, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with the mixture, pack it firmly in a cylindrical glass percolator, and, having closely covered the percolator, macerate for forty-eight hours; then gradually add menstruum, made in the proportion of *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of Alcohol, to *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims] of Water, and allow the percolation to proceed until the Wild Cherry is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract. Dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This preparation has been practically more troublesome than any of the other fluid extracts. We had first Prof. Procter's original process, then his modified one, in which almonds were used to supply emulsin to assist in the development of hydrocyanic acid. (See U. S. D., 15th edition, p. 637.) This was abandoned as too cumbersome in 1870, and we had the glycerin experiment. The fluid extract of 1870 deposited heavily soon after being made, and was immiscible with aqueous liquids without precipitation. These were fatal objections. The present formula is the result of much careful work on the part of the Committee, and it is believed to be an improvement over all its predecessors.* Prof. J. M. Good (*Proc. A. P. A.*, 1897, 220)

* *Fluid Extract of Wild Cherry* (Improved). This process is advocated by Mr. Cyrus M. Boger, who states that all of the hydrocyanic acid is developed, tannin is excluded as much as possible, and consequently precipitation is reduced to the lowest point. "Take of Ground Wild Cherry Bark, *ten troyounces;* Water and Alcohol, each, *ten fluidounces;* Glycerin, *four fluidrachms.* Moisten the bark with *ten fluidounces* of water and put loosely in the percolator, close tightly, and allow it to macerate sixty hours; then pack very firmly, mix the *ten fluidounces* of alcohol and *four* of glycerin and pour it upon the bark; now cork up the percolator tightly and macerate twenty-four hours longer; at the expiration of this time remove the cork, and about *twelve fluidounces* of percolate will come through; water should now be poured on to force the other four fluidounces out, when the percolation should be stopped and the product will be finished." (*A. J. P.*, 1887, pp. 231, 232.)

prefers repercolation, with a menstruum composed of one volume each of glycerin and alcohol and three volumes of water; each portion of drug is moistened with a mixture of one part of glycerin and two parts of water. It is of a very dark wine color, of a rough astringent taste, with a decided odor and taste of hydrocyanic acid. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.).

EXTRACTUM QUASSIÆ. U. S. Extract of Quassia.

(ĘX-TRĂC'TŲM QUÄS'SI-Æ.)

Extrait de Quassie (Bois amer), *Fr.;* **Quassia-Extrakt,** *G.*

"Quassia, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Water, *a sufficient quantity.* Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Water, pack it firmly in a conical percolator, and gradually pour Water upon it until the infusion passes but slightly imbued with bitterness. Reduce the liquid to three-fourths of its bulk by boiling, and strain; then evaporate, by means of a water-bath, to a pilular consistence." *U. S.*

The British Pharmacopœia (1898) no longer recognizes Extract of Quassia.

According to M. Recluz, sixteen ounces of quassia yield by infusion in water seven drachms of extract; by maceration in alcohol of 19° Baumé, two ounces five drachms and a half. The difference between these quantities is so great that we suspect some mistake in the "Dictionnaire des Drogues," from which we quote, although it is known that alcohol yields a larger proportion of extractive than does water or a mixture of alcohol and water. The extract of quassia is dark brown or black, and excessively bitter. It is apt to become dry and disposed to crumble by time. It concentrates a greater amount of tonic power within a given weight than any other extract of the simple bitters, and may, therefore, be given with great advantage in cases in which it is desirable to administer this class of substances in as small a bulk as possible. The dose is from one to two grains (0·065–0·13 Gm.), to be given in pill. The alcoholic extract is a better preparation, and the yield is greater, although it is not so powerful; but it is probably wisest to adhere to the aqueous extract, on account of its cheapness.

EXTRACTUM QUASSIÆ FLUIDUM. U. S. Fluid Extract of Quassia.

(ĘX-TRĂC'TŲM QUÄS'SI-Æ FLŪ'I-DŬM.)

Extrait liquide de Quassie, *Fr.;* **Flüssiges Quassia-Extrakt,** *G.*

"Quassia, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Quassia is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

An active preparation. Dose, from five to ten minims (0·3–0·6 C.c.).

EXTRACTUM RHAMNI PURSHIANÆ FLUIDUM. U. S. (Br.) Fluid Extract of Rhamnus Purshiana.

(ĘX-TRĂC'TŲM RHĂM'NĪ PŪR-SHI-Ā'NÆ FLŪ'I-DŬM.)

Extractum Cascaræ Sagradæ Liquidum, *Br.;* Liquid Extract of Cascara Sagrada.

"Rhamnus Purshiana, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Rhamnus Purshiana is exhausted. Reserve the first *eight*

hundred cubic centimeters [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract which is in great demand as a popular purgative.* The dose is from fifteen to forty-five minims (0·9–2·7 C.c.).

EXTRACTUM RHEI. U. S., Br. Extract of Rhubarb.

(ĘX-TRĂC'TŲM RHĒ'Ī.)

Extractum Rhei Alcoholicum; Extrait de Rhubarbe, *Fr.;* **Rhubarber-Extrakt,** *G.*

"Rhubarb, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the tincture passes nearly tasteless. Reserve the first *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of the percolate, and set it aside in a warm place, until it is reduced by spontaneous evaporation to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]. Evaporate the remainder of the percolate, in a porcelain vessel, by means of a water-bath, at a temperature not exceeding 70° C. (158° F.), to the consistence of syrup. Mix this with the reserved portion, and continue the evaporation, at or below the before-mentioned temperature, until the mixture is reduced to a pilular consistence." *U. S.*

"Moisten Rhubarb Root, in No. 20 powder, with Alcohol (60 per cent.), and set aside for forty-eight hours; transfer to a percolator; slowly pass as much of the Alcohol as may be sufficient to exhaust the Rhubarb Root. Remove most of the alcohol by distillation, and evaporate the residual liquid to dryness." *Br.*

The British extract (1898) is now nearly identical with the U. S. preparation; the menstruum used for the former is, however, slightly more aqueous. Rhubarb yields all its active matter to water and alcohol; but, unless the evaporation be performed with great care and with a moderate heat, it is certain that the purgative principle is to a greater or less extent injured or dissipated in the process; and the extract may thus become even less efficient than the root. Among other consequences which result from the boiling temperature is the formation of a compound of the tannin and starch, which is insoluble in cold water, and upon its precipitation probably carries with it a portion of the purgative principle. There is, moreover, reason to believe that this principle is volatilizable by heat, and that a portion of it escapes with the vapor. When properly prepared, the extract has decidedly the peculiar odor of rhubarb. The dose is from five to ten grains (0·3–0·65 Gm.).

EXTRACTUM RHEI FLUIDUM. U. S. Fluid Extract of Rhubarb.

(ĘX-TRĂC'TŲM RHĒ'Ī FLŪ'Į-DŬM.)

Extrait liquide de Rhubarbe, *Fr.;* **Flüssiges Rhubarber-Extrakt,** *G.*

"Rhubarb, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a conical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight

* *Aromatic Fluid Extract of Cascara Sagrada* (bitterless?). L. C. Urban prefers lime to magnesia, as suggested by H. B. Gilpin, for making a palatable preparation of Cascara. His process is as follows: 1000 Gm. ground cascara sagrada, 150 Gm. ground liquorice root, and 100 Gm. freshly slaked lime are kneaded with 1000 C.c. of water, allowed to stand twelve hours, and then dried at 50° C. The dried drugs are moistened with 400 C.c. of a menstruum, made by mixing 500 C.c. alcohol and 250 C.c. glycerin with 250 C.c. water, and percolated with sufficient of the menstruum, followed by water, to exhaust the drug. The first 850 C.c. are reserved, then mixed with the balance of the percolate, evaporated to a soft extract, and 12 C.c. of compound spirit of orange. (*Pharm. Rev.*, 1896, 270.)

hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Rhubarb is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 70° C. (158° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

Although the process for the fluid extract of rhubarb of U. S. P. 1870 was an improvement on its predecessors, on the addition of water the fluid extract precipitated heavily, so that syrups or mixtures made with it were very unsightly. As the chief use of the fluid extract is in making such preparations, this was very unfortunate, and constituted sufficient grounds for the abandonment of an official formula in favor of one which will exhaust the root of its purgative properties and yet afford an extract that will remain clear when water is added to it. Mr. Geo. Bille claims that all that is necessary is to exhaust the sixteen troyounces of rhubarb with cold water, evaporate, by means of a water-bath, to twelve fluidounces, and add four fluidounces of glycerin. The present process affords a fluid extract which thoroughly represents the root, but it has in a degree the same objection that the former preparation had, immiscibility with syrups and water with loss of transparency. An alkali or an alkaline carbonate dissolves this precipitate, but its use must be limited. The dose for an adult may be from twenty to thirty minims (1·25–1·9 C.c.) as a purgative, and from five to ten minims (0·3–0·6 C.c.) as a laxative.

EXTRACTUM RHOIS GLABRÆ FLUIDUM. U. S. Fluid Extract of Rhus Glabra.

(ĘX-TRĂC'TUM RHŌ'ĬS GLĀ'BRÆ FLŪ'Į-DŬM.)

Extrait liquide de Sumac, *Fr;* **Flüssiges Sumach-Extrakt,** *G.*

"Rhus Glabra, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of Diluted Alcohol, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Rhus Glabra is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

A formula for this preparation was proposed by Prof. J. P. Remington (*A. J. P.*, 1874, p. 7) which differs from that at present official merely in containing a somewhat larger proportion of glycerin in the menstruum. Experience has shown that this is a valuable preparation of sumach berries, and is a useful addition to mouth and throat washes, gargles, etc.

EXTRACTUM ROSÆ FLUIDUM. U. S. Fluid Extract of Rose.

(ĘX-TRĂC'TUM RŌ'ŞÆ FLŪ'Į-DŬM.)

Extrait liquide de Rose rouge, *Fr.;* **Flüssiges Essigrosenblätter-Extrakt,** *G.*

"Red Rose, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of Diluted Alcohol, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards Diluted Alcohol, until the Red Rose is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted

Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is a useful adjuvant and an elegant astringent. It is of a deep red color, with the agreeable flavor of rose. Wm. C. Alpers prefers repercolation for this fluid extract, stating that even a moderate heat imparts an unpleasant odor to the finished product. (*Proc. A. P. A.*, 1897, 425.) Dose, from one to two fluidrachms (3·75–7·5 C.c.).

EXTRACTUM RUBI FLUIDUM. U. S. Fluid Extract of Rubus.

(ĘX-TRĂC'TUM RŪ'BĪ FLŪ'Į-DŬM.)

Extrait liquide d'Ecorce de Ronce, *Fr.;* Flüssiges Brombeerrinden-Extrakt, *G.*

"Rubus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol and *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, and, having moistened the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Alcohol to *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Water, until the Rubus is exhausted. Reserve the first *seven hundred cubic centimeters* [or 23 fluidounces, 321 minims] of the percolate. Distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of Alcohol and Water, using the last-named proportions, to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract does not differ essentially from that formerly official. It is a very dark reddish-brown, translucent fluid, having the properties of the root in a marked degree. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM RUMICIS FLUIDUM. U. S. Fluid Extract of Rumex.

(ĘX-TRĂC'TUM RŪ'MĮ-CĪS FLŪ'Į-DŬM.)

Fluid Extract of Yellow Dock; Extrait liquide de Patience frisée, *Fr.;* Flüssiges Grindwurzel-Extrakt, *G.*

"Rumex, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Rumex is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

An official fluid extract having a dark yellowish-brown color and the peculiar odor and taste of rumex. The dose is a fluidrachm (3·75 C.c.).

EXTRACTUM SABINÆ FLUIDUM. U. S. Fluid Extract of Savine.

(ĘX-TRĂC'TUM SĄ-BĪ'NÆ FLŪ'Į-DŬM.)

Extrait liquide de Sabine, *Fr.;* Flüssiges Sadebaum-Extrakt, *G.*

"Savine, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight

hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Savine is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is identical with the fluid extract formerly official. It is a dark greenish-black fluid, not mixing well with aqueous liquids without the use of an emulsifying agent. It is rarely given internally. The dose is from three to eight minims (0·18–0·5 C.c.).

EXTRACTUM SANGUINARIÆ FLUIDUM. U. S. Fluid Extract of Sanguinaria.

(ĘX-TRĂC'TUM SĂN-GUI-NĀ'RI-Æ FLŪ'I-DŬM—săng-gwę-nā'rę-ē.)

Fluid Extract of Bloodroot; Extrait liquide de Sanguinarie, *Fr.;* Flüssiges Blutwurzel-Extrakt, *G.*

"Sanguinaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Acetic Acid, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix Alcohol and Water in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, to which the Acetic Acid had previously been added, and let it macerate, in a well-covered vessel, in a warm place, during forty-eight hours. Then pack it firmly in a cylindrical percolator, and gradually pour menstruum upon it, until the Sanguinaria is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The liquid preparations of sanguinaria all have an unfortunate tendency to precipitate, and this new fluid extract will not prove an exception. It is of a very deep red color. The dose is from three to five minims (0·18–0·3 C.c.).

EXTRACTUM SARSAPARILLÆ FLUIDUM. U. S. (Br.) Fluid Extract of Sarsaparilla.

(ĘX-TRĂC'TUM SĂR-SĄ-PĄ-RĬL'LÆ FLŪ'I-DŬM.)

Extractum Sarsæ Liquidum, *Br.;* Liquid Extract of Sarsaparilla; Liquor Sarsæ; Extrait liquide de Salsepareille, *Fr.;* Flüssiges Sarsaparilla-Extrakt, *G.*

"Sarsaparilla, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol with *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Sarsaparilla is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Sarsaparilla, in No. 40 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (20 per cent.), *a sufficient quantity;* Glycerin, 2 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Divide the Sarsaparilla into three portions. Moisten one portion with *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres of the Alcohol; pack in a percolator; set aside for twenty-four hours; percolate with the Alcohol until a quantity of *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres is obtained. Moisten the second portion of the drug with this liquid; pack in a percolator; set aside for twenty-four hours; percolate with a menstruum obtained by further percolation of the first portion; continue until a quantity of *four fluid ounces* (Imp. meas.) or two hundred cubic centimetres is obtained. Moisten the third portion of the drug with this liquid; pack in a percolator; set aside for twenty-four hours; percolate

with a menstruum obtained by successive percolation through the first and second portions as directed above; collect *eighteen fluid ounces* (Imp. meas.) or nine hundred cubic centimetres from the third percolator; add the Glycerin. The product should measure *one pint* (Imp. meas.) or one thousand cubic centimetres." *Br.*

The British Pharm. (1898) has greatly improved the process for this preparation, having abandoned maceration for repercolation; glycerin is used as a preservative, being added to the reserved portion; the reason for not using the glycerin in the first percolate to aid in the extraction is not apparent. The introduction of a simple fluid extract of sarsaparilla into our Pharmacopœia was judicious, as it enables the physician to associate this medicine with others at his pleasure, and in such proportions as he may deem expedient. He may rely upon the efficiency of the preparation, if made with sufficient care and skill and from good parcels of the root. The U. S. fluid extract is a somewhat thickish, scarcely translucent liquid, of a very dark reddish-brown color, and of a sweetish and a slightly, though persistently, acrid taste. The dose is from thirty to sixty minims (1·9–3·75 C.c.), equivalent to the same number of grains of sarsaparilla in substance. The official dose of the British preparation is from two to four fluidrachms (7·5–15 C.c.).

EXTRACTUM SARSAPARILLÆ FLUIDUM COMPOSITUM. U. S.
Compound Fluid Extract of Sarsaparilla.

(ĘX-TRĂC'TUM SĂR-SA-PA-RĬL'LÆ FLŪ'Ị-DŬM CỌM-PŌŞ'Ị-TŬM.)

Extrait liquide de Salsepareille composé, *Fr.;* Zusammengesetztes flüssiges Sarsaparilla-Extrakt, *G.*

"Sarsaparilla, in No. 30 powder, *seven hundred and fifty grammes* [or 26 ounces av., 199 grains]; Glycyrrhiza, in No. 30 powder, *one hundred and twenty grammes* [or 4 ounces av., 102 grains]; Sassafras, in No. 30 powder, *one hundred grammes* [or 3 ounces av., 231 grains]; Mezereum, in No. 30 powder, *thirty grammes* [or 1 ounce av., 25 grains]; Glycerin, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol and *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, and, having moistened the mixed powders with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol to *six hundred cubic centimeters* [or 20 fluidounces, 138 minims] of Water, until the powder is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough of a mixture of Alcohol and Water, using the last-named proportions, to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

Everything depends in the process upon having the several ingredients equably powdered, mixing them well and duly moistening them, and then packing them properly in the percolator. The moistening of the mixed powders is more easily effected, as they are less disposed to form lumps than is the sarsaparilla powder alone. The preparation is intended to represent, in a concentrated state, the compound decoction of sarsaparilla, having all its ingredients with the exception of the guaiacum wood, which probably adds little to the efficacy of the decoction. It was originally proposed by Wm. Hodgson, Jr. (*Journ. of the Phila. Coll. of Pharm.*, ii. 285); and the official process differs from his mainly in the omission of the guaiacum wood, the resin of which, separating during the evaporation, somewhat embarrassed the process, without adding to the virtues of the extract. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.).

EXTRACTUM SCILLÆ FLUIDUM. U. S. Fluid Extract of Squill.

(ĘX-TRĂC'TUM SCĬL'LÆ FLŪ'Ị-DŬM.)

Extrait liquide de Scille, *Fr.;* Flüssiges Meerzwiebel-Extrakt, *G.*

"Squill, in No. 20 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water,

and, having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the mixture, pack it in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Squill is exhausted. Reserve the first *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract differs from the one official in 1870 in containing no glycerin in the menstruum. It is a clear red liquid, which is useful for combining with stimulant expectorants, such as ammonium carbonate, which are incompatible with the official syrup of squill. Prof. J. U. Lloyd recommends diluted acetic acid for a menstruum, and that this fluid extract should be made half strength,—*i.e.*, 2 C.c. represent 1 Gm. (See *Am. Drug.*, 1886, p. 202.) The dose of the official fluid extract as an expectorant is from two to three minims (0·12–0·18 C.c.).

EXTRACTUM SCOPARII FLUIDUM. U. S. Fluid Extract of Scoparius.

(ĘX-TRĂC'TUM SCŌ-PĀ'RI-Ī FLŪ'I-DŬM.)

Fluid Extract of Broom.

"Scoparius, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Scoparius is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract. It is difficult to avoid precipitation in the preparation, but fortunately the precipitate is not active. Dose, from twenty to forty minims (1·3–2·6 C.c.).

EXTRACTUM SCUTELLARIÆ FLUIDUM. U. S. Fluid Extract of Scutellaria.

(ĘX-TRĂC'TUM SCŪ-TĘL-LĀ'RI-Æ FLŪ'I-DŬM.)

Fluid Extract of Skullcap; Extrait liquide de Scutellaire, *Fr.*; Flüssiges Helmkraut-Extrakt, *G.*

"Scutellaria, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 400 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Scutellaria is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

A fluid extract, thoroughly representing the activity of Scutellaria. It is of a dark greenish-brown color, and is given in the dose of from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM SENEGÆ FLUIDUM. U. S. Fluid Extract of Senega.

(ĘX-TRĂC'TUM SĔN'Ę-GÆ FLŪ'I-DŬM.)

Extrait liquide de Polygale de Virginie, Extrait liquide de Sénéca, *Fr.*; Flüssiges Senega-Extrakt, *G.*

"Senega, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Ammonia Water, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Alcohol, Water, each, *a sufficient*

quantity, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Ammonia Water with *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol and *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *four hundred and fifty cubic centimeters* [or 15 fluidounces, 104 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and then a mixture of Alcohol and Water, made in the proportion of *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol to *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, until the Senega is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, in a porcelain capsule, to a soft extract; dissolve this in the reserved portion, and add enough of the last-mentioned mixture of Alcohol and Water to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

Formerly Fluid Extract of Senega was very frequently the cause of annoyance to the pharmacist through gelatinization. This was due to the presence of pectinous bodies in the root. The addition of an alkali to the menstruum effectually prevents this, and in this respect the present preparation is a great improvement over the 1870 fluid extract. It is a blackish-brown, moderately thin liquid. Dose, from one to five minims (0·06–0·3 C.c.). For other processes, see *N. R.*, 1883, pp. 195, 196.

EXTRACTUM SENNÆ FLUIDUM. U. S. Fluid Extract of Senna.

(ĘX-TRĂC'TŲM SĔN'NÆ FLŪ'Į-DŬM.)

Extrait liquide de Séné, *Fr.;* Flüssiges Senna-Extrakt, *G.*

"Senna, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol until the Senna is exhausted. Reserve the first *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The official fluid extract of senna of 1870 differed materially from that of the Pharmacopœias of 1850 and 1860, containing neither sugar, oil of fennel, nor Hoffmann's anodyne. It was deemed better to leave to the prescriber the choice of the volatile oil, and to depend for the preservation of the fluid extract upon the glycerin and what might remain of the alcohol after the evaporation. The present official fluid extract, which is practically identical with that of the U. S. P. 1880, is very different from that of 1870, which contained 50 per cent. of glycerin. There is no glycerin in the menstruum now, and there really seems to be no occasion for its use. The fluid extract is a dark, blackish, thick, and somewhat turbid liquid, with a strong flavor of senna. The dose is from one to four fluidrachms (3·75–15 C.c.) for an adult. In consequence of its griping tendency, it should be mixed with one of the volatile oils, as of fennel, anise, or caraway, in the proportion of about two minims (0·12 C.c.) to the fluidounce (30 C.c.). It is well adapted for exhibition with saline cathartics, such as Epsom salt or cream of tartar, which also obviate its griping. In this case not more than one-half of the full dose of the fluid extract should be given at once.

EXTRACTUM SERPENTARIÆ FLUIDUM. U. S. Fluid Extract of Serpentaria.

(ĘX-TRĂC'TŲM SĔR-PĘN-TĀ'RĮ-Æ FLŪ'Į-DŬM.)

Fluid Extract of Virginia Snake Root; Extrait liquide de Serpentaire, *Fr.;* Flüssiges Schlangenwurz-Extrakt, *G.*

"Serpentaria, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims]

of Alcohol with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Serpentaria is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This, though simply a concentrated tincture, is a good preparation, containing the virtues of the root within a small bulk. The fluid extract of serpentaria originated with Mr. J. C. Savery, whose formula was published in the eleventh edition of the U. S. Dispensatory (page 713). It was afterwards modified by Mr. A. B. Taylor (*A. J. P.*, xxv. 206). In the present preparation the alcoholic strength of menstruum is slightly less than that of the fluid extract of U. S. P. 1870. The fluid extract is thin, reddish brown, and transparent, having the peculiar bitterness and odor of the root in perfection. Dose, from twenty to thirty minims (1·25–1·9 C.c.).

EXTRACTUM SPIGELIÆ FLUIDUM. U. S. Fluid Extract of Spigelia.

(ĘX-TRĂC'TUM SPĮ-ĢĒ'LĮ-Æ FLŪ'Į-DŬM.)

Fluid Extract of Pink Root; Extrait liquide de Spigélie, *Fr.;* Flüssiges Spigelien-Extrakt, *G.*

"Spigelia, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Spigelia is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This preparation differs from that formerly official in having no glycerin in the menstruum; the U. S. P. 1870 fluid extract had 50 per cent.

The fluid extract of spigelia is a dark-brown, translucent liquid, with the flavor of the root. The dose is from one to two fluidrachms (3·75–7·5 C.c.) for an adult, from ten to twenty minims (0·6–1·25 C.c.) for a child two or three years old, to be repeated morning and evening for three or four days, and then followed by a brisk cathartic. It is, however, most used in connection with the fluid extract of senna; the fluid extract of spigelia and senna formerly official being an excellent combination, which should not have been dropped from the Pharmacopœia.*

EXTRACTUM STILLINGIÆ FLUIDUM. U. S. Fluid Extract of Stillingia.

(ĘX-TRĂC'TUM STĮL-LĬN'ĢĮ-Æ FLŪ'Į-DŬM.)

Extrait liquide de Stillingie, *Fr.;* Flüssiges Stillingia-Extrakt, *G.*

"Stillingia, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Stillingia is exhausted. Reserve the first *eight hundred and fifty cubic centi-*

* *Extractum Spigeliæ et Sennæ Fluidum*, U. S. 1870. *Fluid Extract of Spigelia and Senna.* "Take of Fluid Extract of Spigelia *ten fluidounces;* Fluid Extract of Senna *six fluidounces;* Oil of Anise, Oil of Caraway, each, *twenty minims.* Mix the Fluid Extracts, and dissolve the Oils in the mixture." *U. S.* 1870.

It combines the cathartic property of senna with the anthelmintic virtues of pinkroot, and is a very good vermifuge, being generally acceptable to the stomach, and not offensive to the taste. The dose is from two fluidrachms to half a fluidounce (7·5–15 C.c.) for an adult, from thirty minims to a fluidrachm (1·9–3·75 C.c.) for a child two years old.

meters [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

The glycerin in the menstruum has been abandoned in this fluid extract, which is of a dark reddish-brown color; and the dose is from fifteen to forty-five minims (0·9–2·8 C.c.).

EXTRACTUM STRAMONII SEMINIS. U. S. (Br.) Extract of Stramonium Seed. [Extractum Stramonii, Pharm. 1880.]

(ĘX-TRĂC'TUM STRĄ-MŌ'NI-Ī SĒM'I-NĪS.)

Extractum Stramonii, *Br.;* Extract of Stramonium; Extrait de Semences de Stramoine, *Fr.;* Stechapfelsamen-Extrakt, *G.*

"Stramonium Seed, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity.* Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until *three thousand cubic centimeters* [or 101 fluidounces, 212 minims] of tincture are obtained, or the Stramonium Seed is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; mix this with the reserved portion, and by means of a water-bath, evaporate, at or below the before-mentioned temperature, to a pilular consistence." *U. S.*

"Pack Stramonium Seeds, in No. 40 powder, in a percolator; exhaust the powder by slow percolation with Alcohol (70 per cent.); remove most of the alcohol from the percolate by distillation; evaporate the residual liquid to the consistence of a firm extract." *Br.*

This is the same extract as that official in the U. S. P. (1880), the fact that it is prepared from the seed instead of the leaves being shown by the title, which now has "Seminis" attached. This preparation was omitted from the U. S. Pharmacopœia of 1860, but, in accordance with suggestions made in the U. S. Dispensatory, was reinstated at the revision of 1870. It is an excellent preparation, not only stronger, but more uniform, and therefore more to be relied on, than any other extract of stramonium. As the seeds yield their virtues more freely to spirit than to water alone, the Pharmacopœias have very properly adopted diluted alcohol as the menstruum. The use of 70 per cent. alcohol by the British Pharmacopœia will probably make a stronger extract by rejecting some of the inert constituents of the seeds soluble in water; but, on the other hand, a larger proportion of inert fixed oil will be found in the British extract than in that made by the U. S. process, which employs diluted alcohol. According to the table of Recluz, sixteen ounces of the seed afford two ounces and two drachms of extract by maceration in diluted alcohol, and one ounce and a half by decoction. Dose, from one-sixth to one-quarter of a grain (0·010–0·016 Gm.).

EXTRACTUM STRAMONII SEMINIS FLUIDUM. U. S. Fluid Extract of Stramonium Seed. [Extractum Stramonii Fluidum, Pharm. 1880.]

(ĘX-TRĂC'TUM STRĄ-MŌ'NI-Ī SĒM'I-NĪS FLŪ'I-DŬM.)

Extrait liquide de Semences de Stramoine, *Fr.;* Flüssiges Stechapfelsamen-Extrakt, *G.*

"Stramonium Seed, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity,* To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Stramonium Seed is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum

to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract the menstruum of which is well adapted for thoroughly exhausting the seed. It is of a dark brown color. The dose is from one to two minims (0·06–0·12 C.c.).

EXTRACTUM STROPHANTHI. Br. Extract of Strophanthus.

(ĘX-TRĂC'TŲM STRŌ-PHĂN'THĪ.)

"Strophanthus Seeds, reduced to No. 30 powder, and dried at 110° F. (43·3° C.), 1 *ounce* (Imperial) or 25 grammes; Purified Ether, Alcohol (90 per cent.), Milk Sugar, of each *a sufficient quantity*. Pack the dried powder in a percolator, and, having moistened it with the Ether, macerate for twenty-four hours; then allow percolation to proceed, continuing the addition of the Ether until the liquid passes through colorless. Remove the marc from the percolator, and dry it, gradually heating it to 120° F. (48·9° C.). Again reduce it to powder, repack in the percolator, and moisten with the Alcohol. Macerate for forty-eight hours, then pour on successive quantities of the Alcohol, percolating slowly, until *half a pint* (Imp. meas.) or two hundred and fifty cubic centimetres of liquid is obtained. Evaporate most of the alcohol; transfer the residual liquid to a counterpoised basin; concentrate until the liquid begins to thicken; then add sufficient finely powdered Milk Sugar to produce *two ounces* (Imp.) or fifty grammes of Extract, in powder." *Br.*

This new preparation of the British Pharmacopœia closely resembles an "abstract" of the U. S. P. 1880; an important detail, in our opinion, has been neglected in not washing the fatty matter extracted by the ether with diluted alcohol to remove active constituents held by the fatty substances, then evaporating the solution and incorporating the residue with the extract. The U. S. and Br. processes for the tincture overcome the necessity for the use of ether by employing alcohol containing enough water to leave the fatty matters in the percolator residue, and the same expedient might have proved of value in the process for this preparation.

This extract fills a very decided want of a solid preparation of strophanthus that can be administered in pill and capsule, and is without doubt efficient. The dose as given in the British Pharmacopœia is from one-quarter to one grain (0·016–0·06 Gm.). A grain of it may be considered to represent ten minims of the U. S. tincture of strophanthus.

EXTRACTUM TARAXACI. U. S., Br. Extract of Taraxacum.

(ĘX-TRĂC'TŲM TĄ-RĂX'Ą-CĪ.)

Extract of Dandelion; Extrait de Dent-de-Lion, *Fr.;* **Löwenzahn-Extrakt,** *G.*

"Taraxacum, freshly gathered in autumn, *a convenient quantity*, Water, *a sufficient quantity*. Slice the Taraxacum, and bruise it in a stone mortar, sprinkling Water over it from time to time, until it is reduced to a pulp; then express and strain the juice, and evaporate it in a vacuum-apparatus, or in a shallow porcelain dish, by means of a water-bath, to a pilular consistence. Keep the Extract in a close vessel, and cover its surface with a cloth, which ought to be moistened occasionally with a little ether or chloroform." *U. S.*

"Crush fresh Taraxacum Root; press out the juice; allow the feculence to subside; heat the liquid to 212° F. (100° C.), and maintain the temperature for ten minutes; strain; evaporate to the consistence of a soft extract." *Br.*

This extract is undoubtedly stronger prepared from the root alone than from the whole plant. It is important that the root should be collected at the right season. The juice expressed from it in the spring is thin, watery, and of a feeble flavor; in the latter part of the summer, and in autumn, thick, opaque, cream-colored, very bitter, and abundant, amounting to one-third or one-half its weight. It may be collected in August, and afterwards until severe frost. According to Mr. Squire, frost has the effect of diminishing the bitterness and increasing the sweetness of the root. An extract prepared by inspissating the juice, as in the present U. S. and Br. processes, is much more efficient than that prepared in the old way by decoction. The inspissation should be effected by exposing the juice in shallow vessels to a current of warm dry air, or by evaporation in a vacuum, and should not be unnecessarily protracted. Long exposure during evaporation changes the bitterness of the juice into sweetness, which is a sign of inferiority. In the British process it is wisely directed that before the evaporation of the juice it shall be exposed for a short time to a heat sufficient to coagulate the albumen, which is then separated and rejected as useless; it is indeed injurious, by favoring decomposition. As often found in the shops, the extract is dark-colored, sweet, and in all probability nearly inert. Mr.

Houlton took more than an ounce of it in a day, without any sensible effect. (*P. J. Tr.*, i. 421.) When prepared from the root and leaves together, it has a greenish color. Mr. Brande states that one cwt. of the fresh root affords from twenty to twenty-five pounds of extract by decoction in water. The expressed juice yields from 11 to 25 per cent. of extract, the greatest product being obtained from plants collected in November, and the least in April and May. This extract deteriorates by keeping, and the official direction to apply occasionally the vapor of chloroform or ether to the surface is useful in this connection. It is conveniently given in an aromatic water. The dose is from a scruple to a drachm (1·3–3·95 Gm.) three times a day.

EXTRACTUM TARAXACI FLUIDUM. U. S. (Br.) Fluid Extract of Taraxacum.

(ĘX-TRĂC'TUM TA-RĂX'Ą-CĪ FLŪ'Į-DŬM.)

Extractum Taraxaci Liquidum, *Br.;* Liquid Extract of Dandelion; Fluid Extract of Dandelion; Extrait liquide de Pissenlit, *Fr.;* Flüssiges Löwenzahn-Extrakt, *G.*

"Taraxacum, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Diluted Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Diluted Alcohol, and pack it firmly in a cylindrical percolator; then add enough Diluted Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Diluted Alcohol, until the Taraxacum is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate; distil off the Alcohol from the remainder by means of a water-bath, and evaporate the residue to a soft extract; dissolve this in the reserved portion, and add enough Diluted Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

"Taraxacum Root, dried, in No. 20 powder, 20 *ounces* (Imperial) or 1000 grammes; Alcohol (60 per cent.), 2 *pints* (Imp. meas.) or 2000 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the powdered Taraxacum Root with the Alcohol; set aside in a closed vessel for forty-eight hours; press out *ten fluid ounces* (Imp. meas.) or five hundred cubic centimetres of liquid; set the latter aside; mix the pressed residue with *two pints* (Imp. meas.) or two thousand cubic centimetres of the Distilled Water; set aside for forty-eight hours; press out and strain the liquid; evaporate to about *ten* [*fluid*] *ounces* (Imp. meas.) or five hundred cubic centimetres; mix the two liquids; if necessary make up the volume to *twenty fluid ounces* (Imp. meas.) or one thousand cubic centimetres by the addition of Distilled Water; filter." *Br.* It is to be regretted that the Br. Pharm. (1898) did not adopt percolation for this preparation, as it can be practised here with great success.

The activity depends more upon the proper selection of the root than upon anything else. The process of exhausting the drug is not difficult, and one of the best tests of this fluid extract is its bitter taste. It is a blackish, moderately thick liquid, which may be given in doses of from one to three fluidrachms (3·75–11·25 C.c.).

EXTRACTUM TRITICI FLUIDUM. U. S. Fluid Extract of Triticum.

(ĘX-TRĂC'TUM TRĬT'Į-CĪ FLŪ'Į-DŬM.)

Fluid Extract of Couch-grass Root; Extrait liquide de petit Chiendent, *Fr.;* Flüssiges Queckenwurzel-Extrakt, *G.*

"Triticum, finely cut, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Pack the Triticum in a cylindrical percolator, pour Boiling Water upon it, and allow the percolation to proceed, supplying boiling water, as required, until the Triticum is exhausted. Evaporate the percolate to *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims], and, having added to it *two hundred and fifty cubic centimeters*] or 8 fluidounces, 218 minims] of Alcohol, mix well and set it aside for forty-eight hours. Then filter the liquid and add to the filtrate enough of a mixture of Alcohol and Water made in the proportion of *one volume* of Alcohol to *three volumes* of Water to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

In making this fluid extract in warm weather, it is advisable to *commence* evaporating the percolate before the drug is exhausted, or fermentation may set in; triticum contains fermentable sugars, and dilute aqueous solutions do not keep well.

This fluid extract is a valuable preparation. The German Pharmacopœia directs an *Extrac-*

tum Graminis, made by digesting 1 part of Triticum with 6 parts of hot water for six hours, straining, evaporating to a syrup, mixing 1 part of this extract with 4 parts of cold distilled water, filtering, and evaporating to an extract. The fluid extract is preferable, as the excessive use of heat is avoided. The dose is from three to six fluidrachms (11·25–22·5 C.c.).

EXTRACTUM UVÆ URSI. U. S. Extract of Uva Ursi.

(ĘX-TRĂC'TUM Ū'VÆ ŪR'SĪ.)

"Uva Ursi, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*. Mix *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Uva Ursi is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate; evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Mix this with the reserved portion, and evaporate, at or below the before-mentioned temperature, on a water-bath, to a pilular consistence." *U. S.*

On account of its efficiency and its capability of being given in capsule, this new preparation ought to be extremely popular. Dose, from five to ten grains (0·33–0·65 Gm.).

EXTRACTUM UVÆ URSI FLUIDUM. U. S. Fluid Extract of Uva Ursi.

(ĘX-TRĂC'TUM Ū'VÆ ŪR'SĪ FLŪ-Ị-DŬM.)

Extrait liquide de Busserole, *Fr.;* Flüssiges Bärentraubenblätter-Extrakt, *G.*

"Uva Ursi, in No. 30 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix the Glycerin with *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol and *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, and, having moistened the powder with *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of the mixture, pack it firmly in a cylindrical glass percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding, first, the remainder of the menstruum, and afterwards a mixture of Alcohol and Water, made in the proportion of *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of Alcohol to *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, until the Uva Ursi is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough of the mixture of Alcohol and Water to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This preparation is a thickish, black liquid, of a sweet, bitterish, astringent, but not very disagreeable taste. The dose is from thirty minims to a fluidrachm (1·9–3·75 C.c.).

EXTRACTUM VALERIANÆ FLUIDUM. U. S. Fluid Extract of Valerian.

(ĘX-TRĂC'TUM VA-LĒ-RĮ-Ā'NÆ FLŪ'Ị-DŬM.)

Extrait liquide de Valériane, *Fr.;* Flüssiges Baldrian-Extrakt, *G.*

"Valerian, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it firmly in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator,

macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Valerian is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ drachms]." *U. S.*

This is a concentrated tincture, strong both in alcohol and in the virtues of valerian. It is probable that all or nearly all the volatile ingredients of the root are extracted by the reserved portion which first passes, and which, not being exposed to evaporation, loses none of the volatile oil and acid that have been dissolved; while the soluble matter subsequently extracted, consisting chiefly of the fixed principles, will not be dissipated by the concentration ordered. The fluid extract may therefore be considered as fully representing the virtues of the root. The formula is, with some modification, that of Prof. Grahame (*A. J. P.*, xxi. 379). The preparation is a dark brownish-red liquid, transparent in thin layers, with the smell and taste of valerian. The dose is about a fluidrachm (3·75 C.c.).

EXTRACTUM VERATRI VIRIDIS FLUIDUM. U. S. Fluid Extract of Veratrum Viride.

(ĘX-TRĂC'TUM VĘ-RĀ'TRĪ VĪR'Į-DĪS FLŪ'Į-DŬM.)

Extrait liquide de Vératre américain, *Fr.*; Flüssiges Grüngermerwurz-Extrakt, *G.*

"Veratrum Viride, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Veratrum Viride is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

It may be doubted whether this fluid extract is among those demanded by the wants of the profession. We have already a tincture, which, supposing none of the virtues of the medicine to be lost in preparing the fluid extract, will be at least half as strong, and at all events is quite strong enough. It is true that the proportion of alcohol is somewhat less in the fluid extract; but in so powerful a preparation this is of little consequence. The tincture itself purports to be saturated; and, though it is probable that, by the concentration of the alcoholic solution, more of the active matter is held by it in the same measure of alcohol than by the tincture, the necessity of multiplying the number of preparations of a powerful drug where the dose is small is not apparent. It would be injudicious to prescribe more of it, as a commencing dose, than from one to two minims (0·06–0·12 C.c.).

EXTRACTUM VIBURNI OPULI FLUIDUM. U. S. Fluid Extract of Viburnum Opulus.

(ĘX-TRĂC'TUM VĪ-BŪR'NĪ ŎP'Ū-LĪ FLŪ'Į-DŬM.)

Fluid Extract of Cramp Bark.

"Viburnum Opulus, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters* [or 10 fluidounces, 69 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually

adding menstruum, using the same proportions of Alcohol and Water as before, until the Viburnum Opulus is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a new official fluid extract: there seems to be little necessity for two fluid extracts of viburnum. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM VIBURNI PRUNIFOLII FLUIDUM. U. S. Fluid Extract of Viburnum Prunifolium.

(ĘX-TRĂC'TUM VĪ-BŬR'NĪ PRŪ-NĮ-FŌ'LĮ-Ī FLŪ'Į-DŬM.)

Fluid Extract of Black Haw; Extrait liquide de Viburné, *Fr.*

"Viburnum Prunifolium, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Mix *seven hundred and fifty cubic centimeters* [or 25 fluidounces, 173 minims] of Alcohol with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 217 minims] of Water, and, having moistened the powder with *three hundred cubic centimeters*, [or 10 fluidounces, 69 minims] of the mixture, pack it moderately in a cylindrical percolator; then add enough menstruum to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding menstruum, using the same proportions of Alcohol and Water as before, until the Viburnum Prunifolium is exhausted. Reserve the first *eight hundred and fifty cubic centimeters* [or 28 fluidounces, 356 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough menstruum to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This is a fluid extract which well represents the drug. It is of a dark reddish-brown color. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM XANTHOXYLI FLUIDUM. U. S. Fluid Extract of Xanthoxylum.

(ĘX-TRĂC'TUM ZĄN-THŎX'Ȩ-LĪ FLŪ'Į-DŬM—zą̆n-thŏk'sę-lī.)

Fluid Extract of Prickly Ash; Extrait liquide de Frêne épineux, *Fr.*; Flüssiges Zahnwehholz-Extrakt, *G.*

"Xanthoxylum, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Xanthoxylum is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate, and evaporate the remainder to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract thoroughly represents the virtues of the drug. The dose is from one-half to one fluidrachm (1·9–3·75 C.c.).

EXTRACTUM ZINGIBERIS FLUIDUM. U. S. Fluid Extract of Ginger.

(ĘX-TRĂC'TUM ZĮN-ĢĬB'Ę-RĪS FLŪ'Į-DŬM.)

Extrait liquide de Gingembre, *Fr.*; Flüssiges Ingwer-Extrakt, *G.*

"Ginger, in No. 40 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Alcohol, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]. Moisten the powder with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol, until the Ginger is exhausted. Reserve the first *nine hundred cubic centimeters* [or 30 fluidounces, 207 minims] of the percolate,

and evaporate the remainder, at a temperature not exceeding 50° C. (122° F.), to a soft extract; dissolve this in the reserved portion, and add enough Alcohol to make the Fluid Extract measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms]." *U. S.*

This fluid extract is a highly concentrated alcoholic solution of the active principles of ginger. It is transparent, and of a reddish color. Dose, from ten to twenty minims (0·6–1·25 C.c.).

FEL BOVIS. U. S. Oxgall. [Fel Tauri.]

(FĔL BŌ'VĬS.)

"The fresh bile of Bos Taurus, Linné (class, Mammalia; order, Ruminantia)." *U. S.*

Chemical researches of a very thorough character have thrown much light on the subject of the constituents of gall. The most characteristic constituents of all galls, of whatever origin, are, first, the sodium or potassium salts of certain resinous acids known collectively as the "gall-acids," and, secondly, certain coloring matters known as "gall-pigments." The gall acids thus far made known are *glycocholic acid*, $C_{26}H_{43}NO_6$; *taurocholic acid*, $C_{26}H_{45}NSO_7$; *hyoglycocholic acid*, $C_{27}H_{43}NO_5$; *hyotaurocholic acid*, $C_{27}H_{45}NSO_6$; and *chenotaurocholic acid*, $C_{29}H_{49}NSO_6$. Of these, the first two occur in oxgall as sodium salts, although sometimes (in green gall) the first one is absent. The bilicholic acid and bilifellinic acid of Berzelius, as well as fellic and fellinic acids, appear to have been mixtures. The solutions of these gall-acids, as well as their alkaline salts, give on addition of sugar and a drop of sulphuric acid a clear and strong purplish-red color (Pettenkofer's gall test). Drechsel modifies Pettenkofer's test as follows. Add to the concentrated alkaline solution of the biliary salts syrupy phosphoric acid. Next add a little cane sugar, and heat the test-tube by setting it in the neck of a flask containing boiling water. After a short heating a characteristic red or reddish-violet color will make its appearance, even if only traces of biliary acids are present. (*N. R.*, 1882, p. 120.) They are also decomposed by the action of baryta water into non-nitrogenous acids and amido-compounds, as will be seen in the following reactions:

$$\underset{\text{Glycocholic acid.}}{C_{26}H_{43}NO_6} + H_2O = \underset{\text{Cholic acid.}}{C_{24}H_{40}O_5} + \underset{\text{Glycine.}}{C_2H_5NO_2}$$

$$\underset{\text{Taurocholic acid.}}{C_{26}H_{45}NO_7S} + H_2O = \underset{\text{Cholic acid.}}{C_{24}H_{40}O_5} + \underset{\text{Taurine.}}{C_2H_7NO_3S}.$$

The gall-pigments are such unstable organic coloring matters that their individuality cannot be said to be thoroughly established. The researches of Staedeler (*Verhand. d. Naturf. Ges. in Zürich*, 8) and R. Maly (*Ann. Ch. und Pharm.*, 132, 129) have, however, given us a better knowledge of them. They are *bilirubin*, $C_{32}H_{36}N_4O_6$; *biliverdin*, $C_{32}H_{36}N_4O_9$; *bilifuscin*, $C_{16}H_{20}N_2O_4$ (?); and *biliprasin*, $C_{16}H_{22}N_2O_6$ (?). Of these, the first two seem to exist originally in the gall, and the others are probably derived from them. Hoppe-Seyler (*Deut. Chem. Ges. Ber.*, 7, p. 1065) has shown that the hæmoglobin and hæmatin of the blood can be changed into hydrobilirubin, a derivative of bilirubin, so that the origin of these gall-pigments seems to be clearly shown. Oxgall contains, in addition, *cholesterine*, *choline*, *urea*, fats, which are the *glycerides of acetic and propionic acids*, mucus, and some inorganic salts, such as sodium and potassium chlorides, and sodium, potassium, calcium, and magnesium phosphates. The *sodium glycocholate* and *taurocholate* may be separated in the following manner. Dry ox-bile is treated with absolute alcohol, and the tincture precipitated by ether in excess. Both salts are deposited, and the glycocholate crystallizes upon standing, the taurocholate remaining in an amorphous form, resembling oily or resinous matter. They may be separated more completely by taking advantage of their different relations to lead acetate and subacetate. Both the acids are precipitated by the subacetate, the glycocholate only by the acetate. If the deposit above referred to be dissolved in water, solution of lead acetate will throw down a lead glycocholate, while the addition of the lead subacetate to the remainder will precipitate the taurocholate. The acids may be separated from the salts of lead by sulphuric acid, and then recombined with soda.

Properties. "A brownish-green or dark-green, somewhat viscid liquid, having a peculiar, unpleasant odor, and a disagreeable, bitter taste. Specific gravity, 1·018 to 1·028 at 15° C. (59° F.). It is neutral, or has a faintly alkaline reaction on litmus paper. A mixture of 2 drops of Oxgall and 10 C.c. of water, when treated, first with a drop of a freshly-prepared solution of 1 part of sugar in 4 parts of water, and afterwards with sulphuric acid, cautiously added, until the precipitate first formed is redissolved, gradually acquires a brownish-red color changing, successively, to carmine, purple, and violet." *U. S.*

FEL BOVIS PURIFICATUM. U. S. (Br.) Purified Oxgall.

(FĔL BŌ'VĬS PŪ-RĬ-FĬ-CĀ'TŬM.)

"The purified gall of the Ox; Bos Taurus." *Br.* 1885.

Fel Bovinum Purificatum, *Br.*, Purified Ox Bile; **Fel Tauri Depuratum,** *P. G.;* **Extractum Fellis Bovini; Fiel de Bœuf purifiée,** *Fr.;* **Gereinigte Ochsengalle (Rindsgalle),** *G.*

"Fresh Oxgall, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Evaporate the Oxgall, in a tared porcelain capsule, on a water-bath, to about *one hundred grammes* [or 3 ounces av., 230 grains], then add to it the Alcohol, mix the whole thoroughly, and set it aside, well covered, for three or four days. Then decant the clear solution, filter the remainder, and, having mixed the liquids and distilled off the Alcohol, evaporate the remainder to a pilular consistence." *U. S.*

"Evaporate *one pint* (Imperial measure) or five hundred cubic centimetres of fresh Ox Bile to one quarter of its volume; shake it with *half a pint* (Imp. meas.) or two hundred and fifty cubic centimetres of Alcohol (90 per cent.); set the mixture aside until the solid matter has subsided; decant the clear solution, and filter the remainder, washing the filter and contents with a little more Alcohol (90 per cent.). Distil off most of the Alcohol from the mixed liquids, and evaporate the residue in a porcelain dish, by the heat of a water-bath, until it acquires the consistence of a thick extract." *Br.*

The object of this preparation is to furnish purified concentrated Oxgall in a condition fitted for internal administration. The addition of Alcohol to the concentrated liquid is for the purpose of separating mucilaginous matter.

Properties. The U. S. Pharmacopœia describes Purified Oxgall, and requires it to respond to the following tests: "A yellowish-green, soft solid, having a peculiar odor, and a partly sweet and partly bitter taste. Very soluble in water and in alcohol. A solution of 1 part of Purified Oxgall in about 100 parts of water behaves towards sugar and sulphuric acid in the same manner as the solution mentioned under Oxgall (see *Fel Bovis*). An aqueous solution of Purified Oxgall should be clear, and should remain transparent upon the addition of an equal volume of alcohol (evidence of proper purification)." "A yellowish-green hygroscopic substance, having a taste partly sweet and partly bitter, soluble in *water* and in *alcohol* (90 per cent.). A solution in twenty or thirty times its weight of *water*, when treated, first with a drop of freshly made syrup consisting of one part of Refined Sugar and four of *water*, and then with *sulphuric acid* cautiously added until the precipitate at first formed is redissolved, gradually acquires a cherry-red color, which changes in succession to carmine, purple, and violet. Its aqueous solution gives no precipitate on the addition of *alcohol* (90 per cent.) (absence of unpurified ox bile)." *Br.*

Refined oxgall, much used by painters, is prepared, according to Gray, in the following manner. Take of "fresh oxgall, one pint; boil, skim, add one ounce of alum, and keep it on the fire for some time; to another pint, add one ounce of common salt in the same manner; keep them bottled up for three months; then decant off the clear; mix them in an equal proportion; a thick yellow coagulum is immediately formed, leaving the refined gall clear and colorless."

Medical Properties and Uses. Bile was formerly highly valued as a remedy in numerous complaints, and was considered peculiarly applicable to cases attended with deficient biliary secretion. Its use has, however, passed out of vogue, perhaps with insufficient reason. We have employed it in large doses in *catarrhal jaundice* with apparently excellent results. Also, at our suggestion it has been used by a veterinary surgeon as a local application to sinuses and foul sores in horses, with favorable reports; whilst recent researches show that the bile of venomous snakes, and probably to a less extent the bile of other animals, is antidotal to snake venom. (See *Snake Venom*, PART II.) The dose of Purified Oxgall is from five to twenty grains (0·33–1·30 Gm.).

FERRI ARSENAS. Br. Iron Arsenate. [Arseniate of Iron, 1885.]

(FĔR'RĪ ĂR-SĒ'NĂS.)

"Ferrous arsenate, $Fe_3(AsO_4)_2,6H_2O$, with ferric arsenate and some iron oxide." *Br.*

Ferrous Arsenate; Arséniate de Fer, *Fr.;* **Arsensaures Eisen,** *G.*

"Ferrous Sulphate, 20¾ *ounces* (Imperial) or 415 grammes; Sodium Arsenate, dried, 26½ *ounces* (Imp.) or 530 grammes; Sodium Bicarbonate, 4½ *ounces* (Imp.) or 90 grammes; Distilled Water, boiling, *a sufficient quantity*. Dissolve the Sodium Arsenate in about *five pints* (Imp. meas.) or two litres, and the Ferrous Sulphate in about *six pints* (Imp. meas.) or two

thousand four hundred cubic centimetres of the Distilled Water; mix the solutions; add the Sodium Bicarbonate dissolved in a little cold Distilled Water; stir thoroughly; collect the resulting precipitate on a calico filter; wash until free from sulphates; squeeze the washed precipitate between folds of strong linen in a screw press; dry it on porous bricks in a warm air-chamber, the temperature of which does not exceed 100° F. (37·8° C.)." *Br.*

This is an official salt of the British Pharmacopœia, which as yet is the only one that has adopted it. The washed precipitate described in the process is ferrous arsenate ($Fe_3As_2O_8$). A portion of ferrous arsenate remains dissolved in the solution. This is precipitated by the sodium bicarbonate, with the evolution of carbonic acid gas.

Ferrous arsenate is white when first formed, but quickly turns green on exposure to the air during the process of washing and drying, and finally becomes a ferroso-ferric arsenate of the probable composition $3Fe(FeO)AsO_4.16H_2O$. It is an amorphous powder, without smell or taste, insoluble in water, but readily dissolved by hydrochloric acid. The British Pharmacopœia gives the following characters of the salt: "A tasteless amorphous powder of a greenish color, insoluble in *water*, but readily dissolved by *hydrochloric acid*. It affords the reactions characteristic of ferrous and ferric salts and of arsenates. Each gramme dissolved in an excess of *sulphuric acid* diluted with *water* should not cease to give a blue precipitate with *solution of potassium ferricyanide* until at least 6·7 cubic centimetres of the *volumetric solution of potassium bichromate* have been added, corresponding to nearly 12½ per cent. of hydrous, or 10 per cent. of anhydrous, ferrous arsenate. It should yield no characteristic reaction with the tests for sulphates." The quantitative test proves that there is a due proportion of ferrous oxide present; for the potassium bichromate oxidizes the ferrous oxide, and until this is wholly converted into ferric oxide a blue precipitate continues to be produced, ceasing, however, when the conversion is complete.

Medical Properties. Ferrous arsenate is said to unite the virtues of the two metals which enter into its composition; but the quantity of iron in any permissible dose is so small as to be nearly or quite insignificant; and the activity of the medicine is in fact due to the arsenic alone. The complaints in which it has been found efficient are those in which arsenic in other forms has proved to be a most valuable remedy; and, judging from our own observation, there is no one of them in which the common solution of potassium arsenite will not produce all the effects that can be obtained from the arsenical preparations, with which this ought undoubtedly to be ranked rather than with the chalybeates. Should the coexistence of an anæmic state of the system with any disease requiring the use of arsenic indicate the joint use of iron, it would be unsafe to depend on ferrous arsenate alone. This remedy is peculiarly useful in chronic affections of the skin, especially those of a scaly character, as *lepra*, *psoriasis*, and the advanced stage of *eczema* and *impetigo*. It is useful also in lupus, and, mixed with twelve times its weight of simple cerate, may be employed externally in cancerous ulcers, though much caution is requisite. The dose is from the eighth to the tenth of a grain (0·008–0·006 Gm.), of which about one-half only is ferrous oxide; given in pill, three times a day. (See *Syrupus Ferri Arsenatis*, PART II., National Formulary.)

FERRI CARBONAS SACCHARATUS. U. S., Br. Saccharated Ferrous Carbonate.

(FĔR'RĪ CĂR'BO-NĂS SĂC-ØHA-RĀ'TŬS.)

"Ferrous oxycarbonate, $xFeCO_3,yFe(OH)_2$, more or less oxidized, mixed with sugar; the ferrous salt, if reckoned as carbonate, $FeCO_3$, forming about one-third of the mixture." *Br.*

Saccharated Iron Carbonate; Saccharated Carbonate of Iron; Ferrum Carbonicum Saccharatum, *P. G.;* Carbonas Ferrosus Saccharatus; Saccharure de Carbonate ferreux, *Fr.;* Zuckerhaltiges Kohlensaures Eisen, *G.*

"Ferrous Sulphate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Bicarbonate, *thirty-five grammes* [or 1 ounce av., 102 grains]; Sugar, in fine powder, Distilled Water, each, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 230 grains]. Dissolve the Ferrous Sulphate in *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of hot Distilled Water, and the Sodium Bicarbonate in *five hundred cubic centimeters* [or 17 fluidounces] of Distilled Water at a temperature not exceeding 50° C. (122° F.), and filter the solutions separately. To the solution of Sodium Bicarbonate contained in a flask having a capacity of about *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] add, gradually, the solution of Ferrous Sulphate, and mix thoroughly by rotating the flask. Fill up the flask with boiling Distilled Water, cork it loosely, and set the mixture aside. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, and then fill the flask

again with hot Distilled Water, and shake it. Again draw off the clear liquid, and repeat the washing with hot Distilled Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally drain the precipitate thoroughly on a muslin strainer, transfer it to a porcelain capsule containing *eighty grammes* [or 2 ounces av., 359 grains] of Sugar, and mix intimately. Evaporate the mixture to dryness, by means of a water-bath, reduce it to powder, and mix intimately with it, if necessary, enough well-dried Sugar to make the final product weigh *one hundred grammes* [or 3 ounces av., 230 grains]. Keep the product in small, well-stoppered bottles." *U. S.*

"Ferrous Sulphate, 2 *ounces* (Imperial) or 40 grammes; Ammonium Carbonate, 1¼ *ounces* (Imp.) or 25 grammes; Distilled Water, boiling, 2 *gallons* (Imp. meas.) or 6400 cubic centimetres; Refined Sugar, 1 *ounce* (Imp.) or 20 grammes. Dissolve the Ferrous Sulphate and the Ammonium Carbonate each in one-quarter of the Distilled Water; add the former to the latter with brisk stirring, in a deep cylindrical vessel; cover this so as to protect it as much as possible from the air; set the mixture aside for twenty-four hours; separate the supernatant liquid from the precipitate by means of a siphon; pour on the remainder of the Distilled Water; stir well; after subsidence remove the clear liquid; collect the precipitate on a calico filter; subject it to expression; triturate it with the Refined Sugar in a porcelain mortar; dry the mixture at a temperature not exceeding 212° F. (100° C.)." *Br.*

This was introduced into the U. S. P. in 1880; the process is identical with that of the former German Pharmacopœia. It is to be regretted that the author of the formula did not adopt the expedient of adding sugar or syrup to the solutions of the two salts, and to the water used for washing, to protect the precipitate as soon as it was formed. When solutions of ferrous sulphate and sodium carbonate are mixed together, there are formed, by double decomposition, sodium sulphate which remains in solution, and ferrous carbonate which falls as a pale-blue precipitate. This precipitate begins immediately to alter in nature by the absorption of oxygen, and, if washed and dried in the ordinary way, becomes ferric oxide, associated with a small quantity of the ferrous carbonate, which has escaped change. As the preparations of iron containing ferrous oxide are the most esteemed, the change which this precipitate undergoes has always been a matter of regret, and various attempts have been made to prevent it. Saccharine matter has been ascertained to possess the required preservative properties; and in the preparation under consideration it is used to prevent the ferrous carbonate as first precipitated from passing into the ferric hydrate.

Dr. Becker, a German physician, was the first to suggest the use of saccharine matter as a means of protection against the absorption of oxygen; and the idea was carried out by Klauer, a German chemist, who first made the saccharated ferrous carbonate. The use of boiling distilled water in the process is to avoid the action of the air contained in unboiled water. The washed precipitate is pressed so as to free it from water as far as possible, and then incorporated with the sugar in fine powder. The mode of treating the precipitate unnecessarily exposes it to the action of the air; and the late London method of incorporating it with the sugar immediately after washing was on this account preferable. The final drying heat should not exceed 54·5° C. (130° F.).* (See *Archiv d. Pharm.*, Jan. 1878; *N. R.*, 1878, 1881.)

Properties. "A greenish-brown powder, gradually becoming oxidized by contact with air, without odor, and having at first a sweetish, afterwards a slightly ferruginous, taste. Only partially soluble in water, but completely soluble in hydrochloric acid, with copious evolution of carbonic acid gas, forming a clear, greenish-yellow liquid. If 1 Gm. of Saccharated Ferrous Carbonate be dissolved in 5 C.c. of hydrochloric acid, and the solution diluted with water to the measure of 50 C.c., portions of this solution will afford a blue precipitate with both potassium ferrocyanide test-solution and potassium ferricyanide test-solution, but should not be affected by barium chloride test-solution (absence of *sulphate*). If 1·16 (1·1573) Gm. of Sac-

* *Saccharated Ferric Oxide. Saccharum Ferrugineum.* This is a combination of sugar and ferric oxide. It is soluble and of a pure sweet taste. According to the method of Siebert, to prepare it dissolve two parts of iron in twenty-four parts of nitric acid, sp. gr. 1·2; evaporate the filtrate to fifteen parts; when *quite cool*, dissolve twelve parts of sugar in the filtrate, and add an excess of a solution of twelve parts of sugar in twelve parts of 20-per-cent. ammonia water. After setting aside for twenty-four hours, precipitate this with four or five times its volume of strong alcohol; collect the precipitate, partially dry with bibulous paper, intimately mix the moist mass with its own weight of powdered sugar, and dry by a moderate heat. It is a good antidote for arsenic. (*A. J. P.*, xl. 324, 326. See also *Neues Repertor. für Pharm.*, xviii. 36.) Keutmann (*Int. Pharm. Gen. Anz.*, 1893, 214) dissolves ferrous sulphate in water, precipitates the solution (placed in a bottle) with ammonia water, fills the bottle with water, decants, washing the precipitate repeatedly with hot water; the precipitate is placed in a porcelain dish containing pulverized sugar warmed, a small quantity of alkali added, and hydrogen peroxide added to complete the oxidation; the mixture is then dried.

charated Ferrous Carbonate be dissolved in 10 C.c. of diluted sulphuric acid, and the solution diluted with water to about 100 C.c., it should require about 15 C.c. of potassium permanganate decinormal volumetric solution to impart a permanent pink tint to the liquid, corresponding to about 15 per cent. of ferrous carbonate (each C.c. of the volumetric solution indicating 1 per cent. of pure Ferrous Carbonate)." *U. S.*

Saccharated ferrous carbonate is frequently seen in small coherent lumps, usually of a grayish-brown color, permanent in the air, having a sweet, styptic taste, and wholly and readily soluble in warm hydrochloric acid, diluted with half its volume of water, with effervescence. According to the British Pharmacopœia, it is in "Small coherent lumps or powder, of a brownish-gray color with a sweet, feebly chalybeate taste. It dissolves with effervescence in warm *hydrochloric acid* diluted with half its volume of *water*. Each gramme, dissolved in excess of warm Concentrated Phosphoric Acid and diluted with *water*, should not cease to give a blue precipitate with *solution of potassium ferricyanide* until at least 29 cubic centimetres of the *volumetric solution of potassium bichromate* have been added. It should yield only the slightest characteristic reactions with the tests for sulphates." The presence of ferric oxide is a defect, which is avoided in Vallet's ferruginous mass.

Its solution in dilute hydrochloric acid is but slightly affected by potassium ferrocyanide, showing the presence of the ferric salt in only small proportion, but yields a copious blue precipitate with the ferricyanide, proving the abundance of the ferrous compound. The same solution should give but a very slight precipitate with barium chloride, evincing that very little either of ferrous or of sodium sulphate has escaped the washing process. The quantitative tests determine the quantity of ferrous salt present, requiring the stated amount of the bichromate to convert it into the ferric chloride.

Medical Properties. This preparation is an excellent chalybeate, possessing the advantages of having nearly all the iron in it in the ferrous state, and of being readily soluble in acids. Originally introduced into the official list by the Edinburgh College, it appeared for the first time in the Dublin and London Pharmacopœias of 1850 and 1851. It is undoubtedly more active than the ferric subcarbonate, and must be used in a smaller dose. It is, however, inferior to Vallet's ferruginous mass, in the preparation of which the anti-oxidizing influence of saccharine matter is more fully applied. The dose of the saccharated ferrous carbonate is from five to thirty grains (0·33–1·95 Gm.), given in the form of pill.

FERRI CHLORIDUM. U. S. Ferric Chloride.

$Fe_2Cl_6.12H_2O$; 539·50. (FĔR'RĪ ĊHLŌ'RĮ-DŬM.) $Fe_2Cl_6.12H_2O$; 540·2.

Chloride of Iron; Ferrum Sesquichloratum, *P. G.;* Ferrum Muriaticum Oxydatum, Chloridum vel Chloruretum Ferricum, Ferri Perchloridum; Ferric Chloride; Perchlorure de Fer, Chlorure ferrique, *Fr.;* Eisenchlorid, *G.*

"Iron, in the form of fine, bright wire, and cut into small pieces, *fifteen grammes* [or 231 grains]; Hydrochloric Acid, Nitric Acid, Distilled Water, each, *a sufficient quantity*. Introduce the Iron wire into a flask having a capacity of about *two hundred cubic centimeters* [or 6 fluidounces, 366 grains], pour upon it *fifty-four grammes* [or 1 fluidounce, 274 minims] of Hydrochloric Acid, previously diluted with *twenty-five cubic centimeters* [or 405 minims] of Distilled Water, and let the mixture stand in a moderately warm place until effervescence ceases; then heat it to the boiling point, filter it through paper, and, having rinsed the flask and Iron wire with a little hot Distilled Water, pass the rinsings through the filter. To the filtered liquid add *twenty-eight grammes* [or 390 minims] of Hydrochloric Acid, add the mixture, slowly and gradually, in a stream, to *eight grammes* [or 92 minims] of Nitric Acid, contained in a capacious porcelain vessel, and warm gently. After effervescence ceases, apply heat, by means of a sand-bath, until the liquid is free from nitrous odor. Then test a few drops of the liquid, diluted with water, with freshly prepared potassium ferricyanide test-solution. Should this reagent produce a blue color, add a little more Nitric Acid, drop by drop, as long as effervescence is observed, and evaporate off the excess. Then add *five grammes* [or 70 minims] of Hydrochloric Acid, and enough Distilled Water to make the whole weigh *sixty grammes* [or 2 ounces av., 51 grains], and set this aside, covered with glass, until it forms a solid crystalline mass. Lastly, break the salt into pieces, and keep it in a glass-stoppered bottle, protected from light." *U. S.*

This formula of the U. S. Pharmacopœia has been adopted with but little alteration from that of Wittstein. (*Pract. Pharm. Chem.*, Darby's transl., p. 265.) When iron is heated with hydrochloric acid, water is decomposed, the hydrogen escapes with effervescence, and the oxygen uniting with the iron forms ferrous oxide, which reacts with the hydrochloric acid to

form water and ferrous chloride.* The next step of the process is to convert the ferrous chloride into the ferric salt. This is effected by treating it with hydrochloric and nitric acids and heating till red fumes no longer escape. The following reaction explains this: $6FeCl_2 + 2HNO_3 + 6HCl = 3Fe_2Cl_6 + 2NO + 4H_2O$. The solution is then evaporated, and, on cooling, concretes into a crystalline mass. The relative proportions of iron and the two acids are adjusted very nearly to the production of these results. There are two crystallized hydrates, one, $Fe_2Cl_6 + 6H_2O$, which is very deliquescent, the other, $Fe_2Cl_6 + 12H_2O$, which is less so, but which, when stood over sulphuric acid, liquefies and slowly deposits crystals of the first hydrate, $Fe_2Cl_6 + 6H_2O$, losing half of its water of hydration.†

Properties. It is in fragments of a crystalline structure, an orange-yellow color, inodorous, and of a strong chalybeate and styptic taste and an acid reaction. It is "very deliquescent in moist air. Freely and completely soluble in water and in alcohol; also in a mixture of 1 part of ether and 3 parts of alcohol. At 35·5° C. (96° F.) the salt melts, forming a reddish-brown liquid. When strongly heated, it decomposes with the loss of water and hydrochloric acid, while the anhydrous salt sublimes, leaving a residue of ferric oxide. The dilute, aqueous solution of the salt is acid to litmus paper, yields a brownish-red precipitate with ammonia water, a blue one with potassium ferrocyanide test-solution, and a white one, insoluble in nitric acid, with silver nitrate test-solution. If the iron be completely precipitated from a solution of the salt by an excess of ammonia water, the filtrate should be colorless, and should not yield either a white or a dark-colored precipitate with hydrogen sulphide test-solution (absence of *zinc* or *copper*); nor should it leave a fixed residue on evaporation and gentle ignition (absence of *salts of the fixed alkalies*). On adding a clear crystal of ferrous sulphate to a cooled mixture of equal volumes of concentrated sulphuric acid and a moderately dilute solution of the salt, the crystal should not become colored brown, nor should there be a brownish-black color developed around it (absence of *nitric acid*). If to a dilute solution of the salt a few drops of freshly prepared potassium ferricyanide test-solution be added, a pure brown color should be produced, without a tinge of green or greenish-blue (absence of *ferrous salt*). A 1-per-cent. aqueous solution of the salt, when boiled in a test-tube, should remain clear (absence of *oxychloride*). If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.), in 10 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require 20 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.* It contains a variable proportion of water according to the crystalline forms it is made to assume, having about 40 per cent., or twelve mols., when in fine acicular crystals, and only 22 per cent., or five mols. when in the form of larger tables. (*Brande and Taylor.*) Its solution in water gives with ammonia a brown precipitate of ferric oxide, and does not yield a blue one with potassium ferricyanide, proving the absence of ferrous chloride.

Ferric chloride is used almost exclusively in the form of tincture or liquor; and in reference to its effect and application we refer to *Tinctura Ferri Chloridi* and *Liquor Ferri Chloridi*. Excepting deliquescence, it keeps without change. When used, it may be dissolved in water in such proportions as may be required. Six, three, two, and one and a half drachms to a fluidounce of water have been recommended; the stronger solutions being used in the treatment of varices, the weaker for injection into *aneurisms*, and for application to bleeding surfaces, etc. Mr. J. Z. Lawrence, of England, has used it as a styptic in a semi-deliquesced state and found it extremely efficient. He keeps it in a bottle, in which it gradually deliquesces; and while it is in this condition he applies the thick liquid portion, by means of a brush of spun glass, to the bleeding surface.

* The Paris Pharmaceutical Society have adopted the following preparations of ferrous chloride, made by dissolving iron in hydrochloric acid and evaporating the filtered solution rapidly to dryness.

Syrup of Ferrous Chloride. Dissolve 5 grammes of dry ferrous chloride in 20 grammes of orange-flower water, and add 800 grammes syrup of gum and 175 grammes syrup of orange-flower. (See, also, *Syrupus Ferri Protochloridi*, PART II., National Formulary.)

Pills of Ferrous Chloride. Dry ferrous chloride, powdered marshmallow-root, each 10 grammes, mucilage sufficient. Make into 100 pills, which are to be silvered.

† *Syrupus Ferri Chloridi* (Edel). *Syrup of Iron Chloride.* Take of Solution of Chloride of Iron (U. S. P.), 160 minims; Potassium Citrate, 224 grains; Citric Acid, 60 grains; Water, 8 fluidounces; Glycerin, 5 fluidounces; Syrup, 16 fluidounces. Dissolve the potassium citrate and citric acid in the water, add the iron solution, and when the reaction ceases filter the solution, then add the glycerin and syrup. (*Drug. Circ.*, 1894, 246.)

FERRI CITRAS. U. S. Ferric Citrate.

(FĔR'RĪ CĪ'TRĂS.)

Citrate of Iron; Ferrum Citricum Oxydatum, *P. G.*; Citras Ferricus; Ferric Citrate, *E.*; Citrate de Sesquioxyde de Fer, Citrate ferrique, *Fr.*; Citronensaures Eisenoxyd, Eisencitrat, *G.*

"Solution of Ferric Citrate, *a convenient quantity*. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.* Ferric citrate as made by the official formula is not a definite chemical salt, but a compound containing ferric citrate, to which the following formula has been assigned: $Fe_2(C_6H_5O_7)_2.6H_2O$; 596·6.

Properties. Ferric citrate is in "thin, transparent, garnet-red scales, without odor, and having a slightly ferruginous taste. Slowly but completely soluble in cold water, and readily soluble in hot water, but diminishing in solubility by age. Insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of *citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt has an acid reaction, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it produces a bluish-green color or precipitate, which is increased and rendered dark blue by the subsequent addition of hydrochloric acid (difference from *iron and ammonium citrate*). When heated with potassium or sodium hydrate test-solution, it affords a brownish-red precipitate, without evolving any vapor of *ammonia*. If a 10-per-cent. solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate be slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride test-solution, and again heated to boiling, will gradually afford a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of *tartrate*). If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having the capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, with the aid of a gentle heat, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 16 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.*

Medical Properties. Ferric citrate was introduced to the notice of the profession, in 1831, by M. Béral, of Paris. It is a pleasant chalybeate, and is best given in solution. Prof. Procter found that a solution of this salt in distilled water, containing 240 grains in a fluidounce, keeps perfectly, and is very convenient for dispensing. Dose of the salt, from three to five grains (0·2–0·33 Gm.). (See *Liquor Ferri Citratis.*)

FERRI ET AMMONII CITRAS. U. S., Br. Iron and Ammonium Citrate.

(FĔR'RĪ ĔT ĄM-MŌ'NI-Ī CĪ'TRĂS.)

Citrate of Iron and Ammonia; Ammonio-Ferric Citrate; Ferri et Ammoniæ Citras, *Br.*; Ferrum Citricum Ammoniatum, *P. G.*; Ferri Ammonio-Citras, Ferro-Ammonium Citricum; Ammonio-Citrate of Iron, Soluble Citrate of Iron, *E.*; Citrate de Fer et d'Ammoniaque (de Fer ammoniacal), Citrate ferrique ammoniacal, *Fr.*; Citronensaures Eisenoxyd-Ammonium (Ammoniak), *G.*

"Solution of Ferric Citrate, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Ammonia Water, *forty cubic centimeters* [or 1 fluidounce, 169 minims]. Mix the solution of Ferric Citrate with the Ammonia Water, evaporate the mixture, by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

"Solution of Ferric Sulphate, 10 *fl. ounces* (Imperial measure) *or a sufficient quantity*, or 200 cubic centimetres or a sufficient quantity; Solution of Ammonia, 23 *fl. ounces* (Imp. meas.) *or a sufficient quantity*, or 460 cubic centimetres or a sufficient quantity; Citric Acid, 4 *ounces* (Imp.) or 80 grammes; Distilled Water, *a sufficient quantity*. Prepare ferric hydroxide as follows: Mix *sixteen fluid ounces* (Imp. meas.) or three hundred and twenty cubic centimetres of the Solution of Ammonia with *two pints* (Imp. meas.) or eight hundred cubic centimetres of

Distilled Water; gradually add to this the Solution of Ferric Sulphate, previously diluted with *two pints* (Imp. meas.) or eight hundred cubic centimetres of Distilled Water; stir constantly and briskly, taking care that ammonia is, finally, in slight excess as indicated by the odor; set aside the mixture for two hours, stirring it occasionally; pour it on a calico filter; when the liquid has drained away, wash the precipitated ferric hydroxide with Distilled Water until free from sulphates.

"Dissolve the Citric Acid in its own weight of Distilled Water; warm the mixture on a water-bath; add the ferric hydroxide, previously well drained; stir them together until nearly the whole of the hydroxide has dissolved, or until the Citric Acid is saturated with ferric hydroxide (prepared, if necessary, from more of the Solution of Ferric Sulphate); let the solution cool; add *five and a half fluid ounces* (Imp. meas.) or one hundred and ten cubic centimetres of Solution of Ammonia; filter through flannel, adding some Distilled Water if necessary; evaporate to the consistence of syrup, the presence of a very slight excess of ammonia being maintained; dry in thin layers on flat porcelain or glass plates at a temperature not exceeding 100° F. (37·8° C.); remove the dry flakes of Iron and Ammonium Citrate." *Br.*

In the U. S. Pharmacopœia, the process consists simply in evaporating a mixture of solution of ferric citrate and ammonia water. In the British, ferric hydrate is first precipitated from a solution of the ferric sulphate, then digested at a moderate heat with a solution of citric acid, and lastly neutralized by ammonia. It has, however, been found by Dr. Squibb that a heat above 82·1° C. (180° F.) acts injuriously in the preparation of the ferric citrate; and the boiling heat directed in the British Pharmacopœia of 1864 was, therefore, improper. (*A. J. P.*, xxvii. 297.) This error has been corrected in the present Br. Pharmacopœia, which directs that the salt should be dried at a heat not above 38° C. (100° F.). In the U. S. formula the ferric citrate is used already prepared, in the British it is prepared in the process. The solution should be concentrated to a syrupy consistence before being poured out on porcelain or glass to dry; and it is important that the heat employed in the concentration should not exceed that indicated. Like most of the scaled iron salts, this preparation is not a true chemical compound, the ammonia not being in the proportion to form a double salt; it would be better to name it "ammoniated iron citrate."

Prof. J. U. Lloyd (*N. R.*, 1879, 323) states that it is usually difficult to adjust accurately the quantity of the ammonia in this process, and proposes to use a definite quantity of a fixed salt, like ammonium citrate, instead. His process will be found in the foot-note.* R. Rother recommends the following method: Dissolve 272 parts of ferric citrate in three or four times its weight of water with heat, add 79 parts of ammonium carbonate, evaporate, and scale in the usual manner. (*A. J. P.*, 1887, p. 166.)

Properties. Iron and ammonium citrate is more soluble than the citrate. It is in "thin, transparent, garnet-red scales, without odor, and having a saline, mildly ferruginous taste; deliquescent in moist air. Readily and completely soluble in water, but insoluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction towards litmus paper (absence of *citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt is neutral to litmus paper. The aqueous solution is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution the solution does not give a blue color or precipitate, unless it be acidulated with hydrochloric acid (difference from *ferric citrate*). When heated with potassium or sodium hydrate test-solution, it affords a brownish-red precipitate, and vapor of ammonia is evolved. If a 10-per-cent. solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride test-solution, and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not

* Prepare a solution of ammonium citrate from citric acid 8 oz. av., and ammonia water q. s.

Add the ammonia water to the citric acid until in slight excess, then evaporate the solution until it measures sixteen fluidounces.

Then take of solution of iron tersulphate 16 fluidounces; citric acid 4 ounces av.; distilled water and ammonia water, each, a sufficient quantity; solution of ammonium citrate 5 fluidounces. Prepare hydrated ferric oxide from the solution of iron tersulphate. Having drained it, place in an evaporating dish and add the citric acid, warm upon a steam or water-bath, and stir until the citric acid is dissolved, then add the solution of ammonium citrate and stir until the hydrated oxide is dissolved, filter and evaporate to the consistence of thick syrup, spread upon glass with a brush, and dry. The yield will be 4234 grains.

yield a white crystalline precipitate (absence of *tartrate*). If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 16 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.* "When incinerated with free access of air, it leaves 31 or 32 per cent. of ferric oxide, which is not alkaline to *litmus* (absence of fixed alkali). Heated with *solution of potassium hydroxide* it evolves ammonia and deposits ferric hydroxide. The alkaline solution from which the iron has separated does not, when slightly supersaturated with *acetic acid*, give any crystalline precipitate (absence of tartrates). It should not yield more than the slightest characteristic reactions with the tests for sulphates" *Br.* Its precise chemical constitution is not determined; but Méhu (*Jahresb.*, 1873, 570), on evaporating a solution of ferrous citrate in ammonia to dryness, obtained a salt of the formula $Fe_2(NH_4)_2.(C_6H_5O_7)_2 + 3H_2O$. This salt is a pleasant chalybeate, in doses of five grains (0·33 Gm.). According to Dr. Paris, it may be mixed with the carbonated alkalies without decomposition, and given in a state of effervescence with citric acid. It should be prescribed when ferric citrate is desired in solution, as it is not suited for administration in the form of pills, owing to the presence of ammonia, which renders it too soluble, and causes the pills to flatten after they have been made, and frequently to cohere in one solid mass. The official ferric citrate should always be used for pills, as it is more slowly dissolved.

FERRI ET AMMONII SULPHAS. U.S. Ferric Ammonium Sulphate.

[Ammonio-Ferric Sulphate. Ammonio-Ferric Alum.]

(FĔR'RĪ ĔT ĄM-MŌ'NĮ-Ī SŬL'PHĂS.)

$Fe_2(NH_4)_2(SO_4)_4.24H_2O$; 962·1. $Fe_2(NH_4)_2(SO_4)_4.24H_2O$; 963·8.

Ferrum Sulfuricum Oxydatum Ammoniatum, *P. G.;* Ferrum Ammonio-Sulphuricum, Ferri Ammonio-Sulphas, Sulphas Ammonico-Ferricus; Sulfate de Fer et d'Ammoniaque, Sulfate de Fer (ferrique) ammoniacal, Alun de Fer ammoniacal, *Fr.;* Schwefelsaures Eisenoxyd-Ammonium, Ammoniakalischer Eisenalaun, *G.*

"Ferric Ammonium Sulphate should be kept in well-stoppered bottles." *U. S.*

The present Pharmacopœia does not give a process for preparing this salt; that of the U. S. P. 1870 will be found below.*

This is an ammonia iron-alum, in which the place of the aluminum oxide (alumina) is occupied by the ferric oxide. It is prepared by heating the solution of ferric tersulphate with ammonium sulphate until the latter salt is dissolved, and then allowing the solution to cool. The two salts unite to form iron and ammonium sulphate, which, being insoluble in the amount of liquid employed, crystallizes when it cools. The process is based on that of Wm. Hodgson (*A. J. P.*, 1856, p. 305).

Ammonio-ferric alum is in "pale violet, octohedral crystals, without odor, and having an acid, styptic taste; efflorescent on exposure to the air. Soluble in 3 parts of water at 15° C. (59° F.), and in 0·8 part of boiling water; insoluble in alcohol. When strongly heated, the crystals fuse, lose their water of crystallization, swell up, and finally leave a pale brown residue. The aqueous solution of the salt has a slightly acid reaction, and yields with potassium ferrocyanide test-solution a blue precipitate; and with barium chloride test-solution a white precipitate insoluble in hydrochloric acid. With potassium or sodium hydrate test-solution it yields a brownish-red precipitate, and if the mixture be heated, vapor of ammonia is evolved. If all the iron be precipitated from a solution of the salt by treating it with an excess of potassium or sodium hydrate test-solution, the resulting filtrate, when neutralized with hydrochloric acid, and then mixed with ammonia water, should not yield a white, gelatinous precipitate (absence of *aluminum*). If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require not less than 11·6 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volu-

* *Ferri et Ammonii Sulphas.* "Take of Solution of Tersulphate of Iron *two pints;* Sulphate of Ammonium *four troyounces and a half.* Heat the Solution of Tersulphate of Iron to the boiling point, add the Sulphate of Ammonium, stirring until it is dissolved, and set the liquid aside to crystallize. Wash the crystals quickly with very cold water, wrap them in bibulous paper, and dry them in the open air." *U. S.* 1870.

metric solution indicating 1 per cent. of metallic iron)." *U. S.* According to H. Rose, the pure salt is white, and gives a colored solution with water, in consequence of the formation of a basic ferruginous salt. This decomposition is prevented by dissolving it in dilute sulphuric acid, when the solution is colorless. Instead of ammonium sulphate, potassium sulphate may be employed with the solution of ferric tersulphate, in which case a potassium iron-alum is produced, called *potassio-ferric alum*, which has all the properties, physical and remedial, of the ammonio-ferric salt; and the two appear to have been indiscriminately used. The iron-alums were brought to the notice of the Pharmaceutical Society of London in Dec. 1853, by Mr. Lindsley Blyth, as a new remedy, prescribed in St. Mary's Hospital. Dr. Tyler Smith found them to be more astringent than common alum, and devoid of the stimulating effects of the other salts of iron. Ferric alum is certainly useful in passive *leucorrhœas*, and its saturated solution has been strongly recommended as a styptic. The dose is from five to ten grains (0·33–0·65 Gm.), to be repeated twice or three times a day.

FERRI ET AMMONII TARTRAS. U. S. Iron and Ammonium Tartrate.

[Ammonio-Ferric Tartrate.]

(FĔR'RĪ ĔT ĄM-MŌ'NĮ-Ī TĂR'TRĂS.)

Ferri Ammonio-Tartras; Ammonio-Tartrate of Iron; Tartrate de Fer et d'Ammoniaque, Tartrate ferrique ammoniacal, *Fr.;* Weinsaures Eisenoxyd-Ammonium, *G.*

"Solution of Ferric Sulphate, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Tartaric Acid, *twenty-nine grammes* [or 1 ounce av., 10 grains]; Distilled Water, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims]; Ammonia Water, Water, each, *a sufficient quantity.* To *one hundred and ten cubic centimeters* [or 3 fluidounces, 345 minims] of Ammonia Water, previously diluted with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of cold Water, add, with constant stirring, the Solution of Ferric Sulphate, previously diluted with *thirteen hundred cubic centimeters* [or 43 fluidounces, 460 minims] of cold Water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about *fifteen hundred cubic centimeters* [or 50 fluidounces, 346 minims] of cold Water, again draw off the clear liquid, and repeat the washing with Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Dissolve one-half of the Tartaric Acid in the Distilled Water, neutralize the solution exactly with Ammonia Water, then add the other half of the Tartaric Acid, and dissolve it by the application of a gentle heat. Now add the moist ferric hydrate, in successive portions, stirring constantly, and continue the heat, which should not exceed 60° C. (140° F.), until the hydrate is dissolved. Filter the solution while hot, evaporate it in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

This process does not differ essentially from that of Prof. Procter. (*A. J. P.*, 1841, p. 276.) Ammonium tartrate is prepared, which is converted into bitartrate by the addition of tartaric acid; and the excess of acid is then combined with ferric hydrate freshly prepared from the official solution of ferric sulphate. A double salt of ammonium and iron tartrate is thus made in solution; by filtering, concentrating, and scaling, the salt is then obtained; this, theoretically, must be considered as consisting of one mol. of tartaric acid and two mols. of base, one consisting of ammonia and the other of ferric oxide, $2(FeO)NH_4,C_4H_4O_6.3H_2O$. It is hardly probable that the salt has exactly this chemical composition, as the scaled salts cannot be said to be definite compounds. The proportion of tartaric acid has been considerably reduced, as it was found to be excessive in previous formulas, and it might be diminished still further with advantage.

This salt is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor of burning sugar, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of *citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt is neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. When heated with potassium or sodium hydrate test-solution, it yields a brownish-red

precipitate, and vapor of ammonia is evolved. If a 10 per cent. solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 17 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.*

It is a mild chalybeate, and may be given in a dose of from ten to thirty grains (0·65–1·95 Gm.).

FERRI ET POTASSII TARTRAS. U. S. (Br.) Iron and Potassium Tartrate. [Potassio-Ferric Tartrate.]

(FĔR'RĪ ĔT PŌ-TĂS'SĮ-I TĂR'TRĂS.)

Ferrum Tartaratum, *Br.;* Tartarated Iron; Tartarus Ferratus, *P. G.;* Ferri Potassio-Tartras, Ferrum Tartarizatum, Tartras Ferrico-Potassicus, s. Potassico-Ferricus, s. Ferrico-Kalicus; Ferro-Tartrate of Potassium; Tartrate de Fer et de Potasse, Tartrate ferrico-potassique, Tartare chalybé, Tartre martial, *Fr.;* Weinsaures Eisenoxyd-Kali, Eisenweinstein, *G.*

"Solution of Ferric Sulphate, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Potassium Bitartrate, *thirty-eight grammes* [or 1 ounce av., 148 grains]; Distilled Water, *three hundred cubic centimeters* [or 10 fluidounces, 69 minims]; Ammonia Water, Water, each, *a sufficient quantity.* To *one hundred and ten cubic centimeters* [or 3 fluidounces, 345 minims] of Ammonia Water, previously diluted with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of cold Water, add, under constant stirring, the Solution of Ferric Sulphate, previously diluted with *thirteen hundred cubic centimeters* [or 43 fluidounces, 460 minims] of cold Water. When the precipitate has subsided, draw off the clear, supernatant liquid by means of a siphon, then mix the precipitate intimately with about *fifteen hundred cubic centimeters* [or 50 fluidounces, 346 minims] of cold Water, again draw off the clear liquid, and repeat the washing with Water in the same manner until the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Then transfer the precipitate to a wet muslin strainer, allow it to drain, and express the water as completely as possible. Mix the Potassium Bitartrate with the Distilled Water in a porcelain vessel, heat the mixture, on a water-bath, to a temperature not exceeding 60° C. (140° F.), and gradually add the moist ferric hydrate, stirring constantly until it is dissolved. Filter the liquid while hot, and let the filtrate stand in a cool, dark place for twenty-four hours. Then stir it well with a porcelain or glass spatula, so that the precipitate which has formed in it may be thoroughly incorporated with the liquid. Now add, very cautiously, just enough Ammonia Water to dissolve the precipitate, evaporate the solution in a porcelain vessel, at or below the above-mentioned temperature, to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

"Solution of Ferric Sulphate, 10 *fl. ounces* (Imperial measure) or 200 cubic centimetres; Solution of Ammonia, 16 *fl. ounces or a sufficient quantity* (Imp. meas.) or 320 cubic centimetres or a sufficient quantity; Acid Potassium Tartrate, in powder, 3 *ounces and* 146 *grains* (Imp.) or 66·5 grammes; Distilled Water, *a sufficient quantity.* Prepare ferric hydroxide from *ten fluid ounces* (Imp. meas.) or two hundred cubic centimetres of Solution of Ferric Sulphate as directed under 'Ferri et Ammonii Citras.'

"Mix the ferric hydroxide intimately with the Acid Potassium Tartrate in a porcelain dish; let the mixture stand for twenty-four hours; heat to a temperature not exceeding 140° F. (60° C.), add gradually *a pint and a half* (Imp. meas.) or six hundred cubic centimetres of Distilled Water; stir constantly until nothing more will dissolve; filter; evaporate at a temperature not exceeding 140° F. (60° C.) to the consistence of syrup; dry in thin layers on flat porcelain or glass plates in a drying closet at a temperature not exceeding 100° F. (37·8° C.); remove the dry flakes of Tartarated Iron." *Br.*

The object of these processes is to combine the excess of acid in the potassium bitartrate with ferric oxide. In both, the plan of Soubeiran in the main is adopted,—namely, that of dissolving the moist ferric hydrate to saturation in a mixture of the bitartrate and water, aided by a moderate heat. The oxide is obtained from the solution of ferric sulphate, which is precipitated by ammonia. Potassa, which was used in the former British process, is not a good precipitant, because the alkali adheres obstinately to the precipitated oxide, and cannot be

completely separated even by repeated washings. The oxide should be gradually added to the bitartrate and water, heated to 60° C. (140° F.), as recommended by Soubeiran, at which temperature the oxide dissolves more readily and in larger quantity than when a higher temperature is employed. Besides, in the latter case, a portion of the ferric oxide is converted into ferrous oxide. (*Gmelin's Handbook*, x. 315.) In the U. S. process the addition of ammonia water to the cooled filtrate dissolves the precipitated insoluble ferric tartrate, and is in accordance with the recommendation of Prof. J. U. Lloyd (*N. R.*, 1879, p. 324), who asserts that this modification renders the salt more soluble without interfering with its stability. G. H. Chas. Klie suggested this improvement in *A. J. P.*, 1876, p. 170. (See, also, *N. R.*, 1878, p. 21.) In both formulas the liquid is poured out on a plane surface, so as to dry in scales. When duly carried into effect, they yield a product at all times identical, and having all the required qualities of the salt. For Roger's process for this salt and the manufacture of *Boules de Mars* (balls of iron and potassium tartrate), see *U. S. D.*, 17th ed., 611.

The late Dr. Ure proposed *ferric tartrate* for medical use. He made it by acting on clean iron filings, or bits of iron wire, with a solution of tartaric acid. It is a pulverulent salt, insoluble in water, and possessing a mild chalybeate taste.

Properties. Iron and potassium tartrate is in "thin, transparent scales, varying in color from garnet-red to reddish-brown, without odor, and having a sweetish, slightly ferruginous taste; slightly deliquescent in the air. Very soluble in water; insoluble in alcohol. When strongly heated, the salt chars, emits fumes having an odor resembling that of burning sugar, and finally leaves a dark brown residue, having a strongly alkaline reaction, and effervescing with acids (distinction from *iron and ammonium tartrate*). The aqueous solution of the salt is neutral to litmus paper, and is not precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it does not afford a blue color or precipitate unless it be acidulated with hydrochloric acid. When heated with potassium or sodium hydrate test-solution, it yields a brownish-red precipitate, and a slight odor of ammonia is evolved. If a 10-per-cent. solution of the salt be deprived of its iron by boiling it with an excess of potassium or sodium hydrate test-solution, the filtrate, when slightly acidulated with acetic acid, will gradually deposit a white, crystalline precipitate. If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 15 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.* "The aqueous solution, when acidulated with *hydrochloric acid*, affords a copious blue precipitate with *solution of potassium ferrocyanide*, but none or only a greenish turbidity with *solution of potassium ferricyanide*. When the salt is boiled with *solution of sodium hydroxide*, a reddish-brown precipitate separates, and the filtered solution, when slightly acidulated with *acetic acid*, yields, as it cools, a crystalline deposit, especially if the solution is previously mixed with a little *alcohol* (90 per cent.). By incinerating 10 grammes at a red heat, washing the residue with *water*, and again incinerating with free access of air, a residue of ferric oxide is obtained weighing not less than 3 grammes." *Br.* According to the view of its nature taken in the U. S. Pharmacopœia, it is a double salt, consisting of one molecule of ferric tartrate and one of potassium tartrate ($Fe_2(C_4H_4O_6)_3 + K_2C_4H_4O_6 + H_2O$). Flückiger (*Pharmaceutische Chemie*, 2d ed., 573, 1888), on the other hand, considers the salt formed to be one in which Fe_2O_2 is present as a bivalent group, and gives it the formula $C_4H_4O_6K_2 + C_4H_4O_6(Fe_2O_2) + 4H_2O$. The salt is incompatible with astringent vegetable infusions, which give rise to a dark-colored precipitate.

Medical Properties. Iron and potassium tartrate is a mild, agreeable chalybeate, with but little astringency. It is well borne by the stomach, whether taken fasting or with the food. From its slight taste and ready solubility, it is one of the best ferruginous preparations for children. Dose for an adult, five to ten grains (0·33–0·65 Gm.), given preferably in solution.

FERRI ET QUININÆ CITRAS. U. S., Br. Iron and Quinine Citrate.

(FĔR'RĪ ĔT QUĪ-NĪ'NÆ CĪ'TRĂS.)

Ferri et Quiniæ Citras, *Br.* 1867, *U. S.* 1870; Citrate of Iron and Quinia; Citrate de Fer et de Quinine, *Fr.*; Chininum Ferro-Citricum, *P. G.*; Citronensaures Eisen-Chinin, *G.*

"Ferric Citrate, *eighty-five grammes* [or 2 ounces, 436 grains]; Quinine, dried at 100° C. (212° F.) to a constant weight, *twelve grammes* [or 186 grains]; Citric Acid, *three grammes*

[or 46 grains]; Distilled Water, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferric Citrate in *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims] of Distilled Water by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid, previously triturated with *twenty cubic centimeters* [or 325 minims] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Lastly, evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

"Solution of Ferric Sulphate, 9 *fl. ounces* (Imperial measure) or 180 cubic centimetres; Quinine Sulphate, 2 *ounces* (Imp.) or 40 grammes; Diluted Sulphuric Acid, 3 *fl. ounces* (Imp. meas.) or 60 cubic centimetres; Citric Acid, 6 *ounces and* 60 *grains* (Imp.) or 123 grammes; Solution of Ammonia, Distilled Water, of each *a sufficient quantity*. Prepare ferric hydroxide from *nine fluid ounces* (Imp. meas.) or two hundred cubic centimetres of Solution of Ferric Sulphate as directed under 'Ferri et Ammonii Citras.'

"Mix the Quinine Sulphate with eight times its weight of Distilled Water; add the Diluted Sulphuric Acid; when the salt is dissolved precipitate the quinine with a slight excess of Solution of Ammonia; collect the precipitate on a filter; wash it with *three pints* (Imp. meas.) or twelve hundred cubic centimetres of Distilled Water.

"Dissolve the Citric Acid in its own weight of Distilled Water; warm the solution on a water-bath; add the ferric hydroxide, previously well drained; stir them together; when the hydroxide has dissolved, add the precipitated quinine; continue the agitation until this also has dissolved; let the solution cool; add, in small quantities at a time, *three fluid ounces* (Imp. meas.) or sixty cubic centimetres of Solution of Ammonia, diluted with *four fluid ounces* (Imp. meas.) or eighty cubic centimetres of Distilled Water; stir briskly, allowing the quinine which separates with each addition of ammonia to dissolve before the next addition is made; filter the solution; evaporate it to the consistence of a thin syrup; dry the latter in thin layers on flat porcelain or glass plates at a temperature of 100° F. (37·8° C.); remove the dry flakes of Iron and Quinine Citrate." *Br.*

The present process differs in several particulars from that formerly official;* the solution of ferric citrate has been replaced by a definite weight of ferric citrate, and, instead of using freshly precipitated quinine, the moisture is driven off entirely, and the perfectly dry alkaloid

* *Liquor Ferri et Quininæ Citratis*, U. S. 1880. *Solution of Citrate of Iron and Quinine.* (Citrate de Fer et de Quinine liquide, *Fr.*; Citronensaures Eisen- und Chinin-Lösung, *G.*) "Citrate of Iron and Ammonium, *sixty-five parts* [or five hundred and sixty-eight grains]; Quinine, dried at 100° C. (212° F.), until it ceases to lose weight, *twelve parts* [or one hundred and five grains]; Citric Acid, *twenty-eight parts* [or two hundred and forty-five grains]; Alcohol, *thirty parts* [or six fluidrachms]; Distilled Water, *a sufficient quantity*, To make *two hundred parts* [or four ounces av.]. Dissolve the Citrate of Iron and Ammonium in *two hundred parts* [or four fluidounces] of Distilled Water, contained in a tared porcelain capsule, heat the solution to 60° C. (140° F.), on a water-bath, add the Citric Acid, and, when it is dissolved, add the Quinine, stirring the mixture until a perfect solution has been obtained. Evaporate this to *one hundred and sixty parts* [or three ounces av.], allow it to cool, add the Alcohol, and finally enough Distilled Water to make the solution weigh *two hundred parts* [or four ounces av.]." *U. S.*

The introduction of this solution in the U. S. P. 1880 grew out of the necessity for a soluble form of iron and quinine citrate. That comparatively insoluble salt, the official iron and quinine citrate, has been but little used; whilst the readily soluble preparation of the manufacturers, which contains ammonia, is in extensive demand, and is official in the U. S. P. 1890. It is believed that the above solution will be satisfactory, as it bears a definite and easily remembered relation towards the official salt (see *Ferri et Quininæ Citras*), being *exactly half its strength*. Its principal use will undoubtedly be by the pharmacist, who will use it in manufacturing and in prescriptions, as it will save him the time and labor of dissolving the salt, whilst the process of assay, which is identical with that given under the salt, will serve as an efficient means of testing the solution should he be compelled to purchase it.

Properties. "A dark greenish-yellow to yellowish-brown liquid, transparent in thin layers, odorless, having a bitter and mildly ferruginous taste, and a slightly acid reaction. On supersaturating the diluted solution with a slight excess of ammonia, the color of the liquid is deepened and a white, curdy precipitate is thrown down, which is soluble in ether and answers to the reaction of quinine (see *Quinina*). A small portion of the filtrate, when mixed with test-solution of potassium ferrocyanide, does not produce a blue color or precipitate, unless it is acidulated with hydrochloric acid. If another portion of the filtrate be deprived of its iron, by boiling with an excess of potassa, the concentrated and cooled filtrate precipitated by test-solution of calcium chloride, and the new filtrate heated to boiling, a white granular precipitate is produced. On heating the solution with potassa, vapor of ammonia is evolved. The solution contains 6 per cent. of quinine. It may be assayed as follows: Dilute 8 Gm. of the solution with water to 30 C.c., introduce it, with any rinsings, into a glass separator, add an aqueous solution of 0·5 Gm. of tartaric acid, and then solution of soda in decided excess. Extract the alkaloid by agitating the mixture with four successive portions of chloroform, each of 15 C.c. Separate the chloroformic layers, mix them, evaporate them in a weighed capsule, on a water-bath, and dry the residue at a temperature of 100° C. (212° F.). It should weigh 0·48 Gm." *U. S.*

Medical Properties. The medical virtues of this solution are those of iron and quinine citrate. It may be given in the dose of from 10 to 20 minims (0·6 to 1·25 C.c.).

is used. There has been very little gained by the change in saving time, because of the slow solubility of both of the citrates, and this is particularly so if the temperature is strictly adhered to. If the quinine be previously triturated with a little citric acid and water, time can be saved. The *official* iron and quinine citrate has never been very largely used, because of its slow solubility, the manufacturers supplying a salt which is readily soluble, due to the presence of ammonia. But by the introduction of a soluble iron and quinine citrate (see *Ferri et Quininæ Citras Solubilis*) the salt may be now furnished in a very convenient form for use in solutions, whilst the above comparatively insoluble salt may be retained for use in pills, for which it is much better adapted.

The use of ferrous sulphate by the former British process is abandoned, and the solution of the persulphate retained. From this the freshly precipitated ferric hydrate is obtained by precipitation with ammonia. The next step is to separate quinine from the sulphate, by simply dissolving the salt in water with the aid of sulphuric acid, and then precipitating by ammonia. Thirdly, the hydrate and quinine are dissolved successively, aided by the heat of a water-bath, in solution of citric acid, whereby an iron and quinine citrate is obtained. The ammonia is added in order to render the iron and quinine citrate more soluble by the agency of a portion of ammonium citrate. It is important that the ammonia should not be added in excess; on the contrary, the solution should retain a slight acid reaction. (Fleurot.) After evaporation, the salt is dried, as in the other process, on glass or porcelain, so as to be obtained in thin scales.

The U. S. and Br. preparations are essentially different; both consist of citric acid, ferric oxide, and quinine, the British, however, containing the important addition of ammonium citrate. No analysis of either salt has been made that determines precisely its chemical composition. Both are undoubtedly mere mixtures of the iron and quinine citrates, the British containing ammonium citrate.

The characters of the U. S. salt, as given in the Pharmacopœia, are the following. "Thin, transparent scales, of a reddish-brown color, without odor, and having a bitter, mildly ferruginous taste; slowly deliquescent in damp air. Slowly but completely soluble in cold water, more readily soluble in hot water, and but partially soluble in alcohol. Its solubility is diminished by age. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (*absence of citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt has an acid reaction. On the addition of a slight excess of ammonia water the color of the solution is deepened, and a white, curdy precipitate is produced. The filtrate from this precipitate does not afford a blue color with potassium ferrocyanide test-solution, unless it be acidulated with hydrochloric acid. Another portion of the filtrate, treated with an excess of potassium or sodium hydrate test-solution, deposits a brownish-red precipitate. If a 10-per-cent. solution of the salt be deprived of its iron and quinine by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride test-solution, and again heated to boiling, gradually deposits a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of *tartrate*).

"*Estimation of the Quinine.* Dissolve 1·12 (1·1176) Gm. of Iron and Quinine Citrate in a capsule, with the aid of a gentle heat, in 20 C.c. of water. Transfer the solution, together with the rinsings of the capsule, to a separator, allow the liquid to become cold, then add 5 C.c. of ammonia water and 10 C.c. of chloroform, and shake. Allow the liquids to separate, draw off the chloroform layer, and shake the residuary liquid a second and a third time with 10 C.c. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0·1288 Gm. (corresponding to at least 11·5 per cent. of dried quinine), and should conform to the reactions and tests of quinine (see *Quinina*).

"*Estimation of the Iron.* Heat the aqueous liquid, from which the quinine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, allow it to cool, and dilute it with water to the volume of 50 C.c. Transfer 25 C.c. of the liquid to a glass-stoppered bottle (having the capacity of about 100 C.c.), add 2 C.c. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour at a temperature of 40° C. (104° F.). After it has been allowed to cool, and been mixed with a few drops of starch test-solution, it should require about 14·5 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.*

The British Pharmacopœia (1898) gives the following description and tests: "In thin scales of a greenish golden-yellow color, somewhat deliquescent. Soluble in half its weight of cold *water*. The solution is very slightly acid, and yields precipitates which are reddish brown with *solution of potassium hydroxide*, white with *solution of ammonia*, blue with *solution of potassium ferrocyanide* and with *solution of potassium ferricyanide*, and grayish black with *solution of tannic acid*. The salt has a bitter, chalybeate taste. When incinerated with free access of air, it leaves a residue which when moistened with *water* is not alkaline to test-paper (absence of fixed alkali). 5 grammes dissolved in 45 cubic centimetres of *water* and treated with a slight excess of *solution of ammonia* should yield a white precipitate, which, when dissolved out by repeated treatment of the liquid with *ether*, and the latter evaporated, and the residue completely dried at 248° F. (120° C.), weighs 0·75 gramme. This precipitate is almost entirely soluble in a little *purified ether;* when burned it leaves but a minute residue; neutralized by *sulphuric acid*, it should answer to the characters of and tests for Quinine Sulphate."

Amorphous quinine or chinoidine is sometimes substituted for the crystallizable alkaloid. For the detection of this fraud, Dr. de Vrij proposes a method which depends upon the fact that oxalic acid forms with crystallizable quinine, in a chloroformic solution, white crystals of quinine oxalate without discoloration. (See *N. R.*, 1881, 10.)

When dissolved by the aid of an acid, it forms a solution which, decolorized by a little purified animal charcoal, turns the plane of polarization strongly to the left,—a character of quinine; cinchonine turning it to the right. (Squire.) The salt is said to be sometimes adulterated by cinchonine, which would be at once detected by the test of solubility in ether and the effect on polarized light, above given. Oscar Zinn (*A. J. P.*, 1877, 550) examined six commercial samples, two of which contained no quinine, but cinchonine. H. G. Drueding found three out of six samples deficient in quinine. As it occurs in the British market, it is of exceedingly variable composition, containing, according to Mr. J. C. Braithwaite, who examined thirty-five different specimens, a proportion of quinine varying from 1·5 to 17 per cent. (*P. J. Tr.*, 1868, 157.) The proportion of alkaloid appears to be usually below the standard. (A. W. Gerrard, *Ibid.*, March, 1873, 763.) According to Mr. C. H. Wood (*Ibid.*, 2d ser., x. 644), this salt undergoes a rapid change of composition when exposed to the direct rays of the sun.

The new official process of assay will doubtless bring to light all shortcomings. (See results of examination of commercial iron and quinine citrate by E. C. Federer, *Proc. Mich. Pharm. Assoc.*, 1887, or *Pharm Era*, 1887, p. 357.)

Iron and quinine citrate combines the virtues of its two bases, and may be given in all cases in which they are jointly indicated, preferably in pill form. The dose, as a tonic, is five or six grains (0·33–0·4 Gm.), containing about half a grain (0·033 Gm.) of dry quinine, three or four times a day. This dose may be increased, if deemed advisable.

FERRI ET QUININÆ CITRAS SOLUBILIS. U. S. Soluble Iron and Quinine Citrate.

(FĔR'RĪ ĔT QUĮ-NĪ'NÆ CĪ'TRĂS SO-LŪ'BĮ-LĬS.)

"Ferric Citrate, *eighty-five grammes* [or 2 ounces av., 436 grains]; Quinine, dried at 100° C. (212° F.) to a constant weight, *twelve grammes* [or 186 grains]; Citric Acid, *three grammes* [or 46 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Dissolve the Ferric Citrate in *one hundred and sixty cubic centimeters* [or 5 fluidounces, 197 minims] of Distilled Water, by heating on a water-bath at a temperature not exceeding 60° C. (140° F.). To this solution add the Quinine and Citric Acid previously triturated with *twenty cubic centimeters* [or 325 minims] of Distilled Water, and stir constantly until the Quinine and Citric Acid are dissolved. Then add gradually, and with constant stirring, *fifty cubic centimeters* [or 1 fluidounce, 331 minims], or *a sufficient quantity*, of Ammonia Water, so that, after the addition of each portion of the latter, the precipitated Quinine will be redissolved and the liquid acquire a greenish-yellow tint. Lastly, evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

This is a new official salt which has been added to the list in answer to a demand which was very persistent. The iron and quinine citrate formerly official and the one in the U. S. P. 1890 are comparatively insoluble salts, and better adapted for use in pills; but the combination

of iron, quinine, and citric acid is wanted more frequently in solution, and hence a salt which will quickly dissolve will be a desirable addition: the only difference between the two salts consists in greater solubility, and this is effected by the use of ammonia water.

The U. S. Pharmacopœia describes it as in "thin, transparent scales, of a greenish, golden-yellow color, without odor, and having a bitter, mildly ferruginous taste; deliquescent in damp air. Rapidly and completely soluble in cold water, but only partially soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide, which should not have an alkaline reaction upon litmus paper (absence of *citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt has a slightly acid reaction. On the addition of a slight excess of ammonia water the color of the liquid is deepened, and a white, curdy precipitate is produced. If a portion of the filtrate from this precipitate be mixed with some potassium ferrocyanide test-solution, it does not afford a blue color or precipitate, unless it be acidulated with hydrochloric acid. Another portion of the filtrate, treated with an excess of potassium or sodium hydrate test-solution, gives a brownish-red precipitate. If a portion of the salt be heated with potassium or sodium hydrate test-solution, vapor of ammonia will be evolved. If a 10-per-cent. solution of the salt be deprived of its iron and quinine by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with a little calcium chloride test-solution, and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not give a white, crystalline precipitate (absence of *tartrate*). Soluble Iron and Quinine Citrate, when assayed for Quinine and Iron by the method described under *Ferri et Quininæ Citras*, should respond to the requirements for the latter." See modification of process by F. A. Sieker (*Pharm. Rund.*, 1895, 36).

FERRI ET STRYCHNINÆ CITRAS. U. S. Iron and Strychnine Citrate.

(FĔR'RĪ ĔT STRĬĢH-NĪ'NÆ CĪ'TRĂS.)

Ferri et Strychniæ Citras, *U. S.* 1870; Citrate de Fer et de Strychnine, *Fr.*; Citronensaures Eisen-Strychnin, *G.*

"Iron and Ammonium Citrate, *ninety-eight grammes* [or 3 ounces av., 200 grains]; Strychnine, *one gramme* [or 15·4 grains]; Citric Acid, *one gramme* [or 15·4 grains]; Distilled Water, *one hundred and twenty cubic centimeters* [or 4 fluidounces, 27 minims]. To make *one hundred grammes* [or 3 ounces av., 230 grains]. Dissolve the Iron and Ammonium Citrate in *one hundred cubic centimeters* [or 3 fluidounces, 181 minims] of Distilled Water, and the Strychnine, together with the Citric Acid, in *twenty cubic centimeters* [or 325 minims] of Distilled Water. Mix the two solutions, evaporate the mixture by means of a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in well-stoppered bottles, protected from light." *U. S.*

Iron and strychnine citrate, although long used in medicine, was first recognized in 1870. The present formula does not differ essentially from that of 1870.

This salt is well adapted for administration in pilular form, but should never be prescribed in solution. Dr. Squibb has shown that a whitish deposit will begin to settle from the solution within two or three hours after it is made, and continue to increase for several days; the deposit was found to contain fifty per cent. of strychnine. When ammonia water or ammonium citrate was added, the precipitate was redissolved, but the solution could not be made permanent by the addition, as the precipitate reappeared. There might be dangerous or alarming symptoms if this solution were dispensed without shaking. (*Ephemeris*, June, 1888, p. 1128.)

Properties. "Thin, transparent scales, varying in color from garnet-red to yellowish-brown, without odor, and having a bitter, slightly ferruginous taste; deliquescent in damp air. Readily and completely soluble in water, but only partly soluble in alcohol. When strongly heated, the salt chars, and finally leaves a residue of ferric oxide which should not have an alkaline reaction upon litmus paper (absence of *citrates* or *tartrates of the fixed alkalies*). The aqueous solution of the salt is slightly acid to litmus paper, and is not immediately precipitated, but rendered darker in color, by ammonia water. With potassium ferrocyanide test-solution it does not yield a blue color or precipitate, unless it be acidulated with hydrochloric acid. On heating it with potassium or sodium hydrate test-solution, a brownish-red precipitate is produced, and vapor of ammonia evolved. If a 10-per-cent. solution of the salt be deprived of its iron and strychnine by boiling it with an excess of potassium or sodium hydrate test-solution, and the filtrate slightly acidulated with acetic acid, a portion of the cooled liquid, mixed with

a little calcium chloride test-solution, and again heated to boiling, will gradually deposit a white, crystalline precipitate. Another portion of the acidulated and cooled liquid, when allowed to stand for some time, should not deposit a white, crystalline precipitate (absence of *tartrate*)." *U. S.*

"*Estimation of the Strychnine.* Dissolve 2·24 (2·2352) Gm. of Iron and Strychnine Citrate, in a separator, in 15 C.c. of water, add 5 C.c. of ammonia water and 10 C.c. of chloroform, and shake. Allow the liquids to separate, draw off the chloroform layer, and shake the residuary liquid a second and a third time with 10 C.c. of chloroform. Allow the combined chloroformic extracts to evaporate spontaneously in a tared capsule, and dry the residue at a temperature of 100° C. (212° F.) to a constant weight. This residue should weigh not less than 0·02 Gm. nor more than 0·0224 Gm. (corresponding to not less than 0·9 nor more than 1 per cent. of strychnine), and should respond to the reactions and tests of strychnine (see *Strychnina*).

"*Estimation of the Iron.* Heat the aqueous liquid, from which the strychnine has been removed in the manner just described, on a water-bath, until the odor of chloroform and ammonia has disappeared, allow it to cool, and dilute it with water to the volume of 100 C.c. Transfer 25 C.c. of the liquid to a glass-stoppered bottle (having the capacity of about 100 C.c.), add 2 C.c. of hydrochloric acid and 1 Gm. of potassium iodide, and allow the mixture to stand for half an hour, at a temperature of 40° C. (104° F.). After it has been allowed to cool, and been mixed with a few drops of starch test-solution, it should require about 16 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.*

Medical Properties. It is an efficient tonic, but has no advantages over the two active substances it contains when given conjointly in an uncombined state, and has the great disadvantage that the dose of one principle cannot be varied independently of that of the other. It occurs in beautiful red scales, of an intensely bitter, scarcely ferruginous taste, and is very soluble in water. It contains 1 per cent. of strychnine, there being in five grains one-twentieth of a grain of the alkaloid. Dose, from three to five grains (0·20–0·33 Gm.), in pill or solution.

FERRI HYPOPHOSPHIS. U. S. Ferric Hypophosphite.

$Fe_2(PH_2O_2)_6$; **501·04.** (FĔR'RĪ HĪ-PŌ-PHŌS'PHĪS.) $Fe_2(H_2PO_2)_6$; 501·8.

Hypophosphite of Iron; Ferrum Hypophosphorosum, Hypophosphis Ferricus; Hypophosphite de Fer, *Fr.;* Unterphosphorigsaures Eisenoxyd, *G.*

"Ferric Hypophosphite should be kept in well-stoppered bottles." *U. S.*

This is among the hypophosphites brought into notice in consequence of their recommendation by Dr. Churchill in the treatment of phthisis, in which they were thought to be useful by the introduction of phosphorus into the system. This particular salt may be considered preferable to others when a marked condition of anæmia indicates a deficiency of iron in the tissues. It may be made by the action of hypophosphorous acid on ferrous carbonate formed by precipitation from the sulphate; but, as some difficulty has been found in obtaining this acid perfectly pure, Mr. C. H. Wood, of London, prefers the plan of double decomposition. He proposes that ferrous sulphate and calcium hypophosphite be made to react on each other in molecular proportions represented by 480 grains of crystallized ferrous sulphate and 326 grains of commercial hypophosphite; in the latter an allowance of 10 per cent. being made for impurities ordinarily found in that salt. These quantities will yield 320 grains of ferric hypophosphite, and the reaction will be represented by the following formula: $Ca(H_2PO_2)_2 + FeSO_4 = CaSO_4 + Fe(H_2PO_2)_2$. Calcium sulphate is precipitated, and ferrous hypophosphite is held in solution. (*P. J. Tr.*, 1868, p. 342.) In this condition the salt is a ferrous compound; but on evaporation the ferrous salt becomes ferric, and acquires the properties detailed in the Pharmacopœia. Of this the following description is given in the late edition of that work.

Properties. "A white or grayish-white powder, odorless and nearly tasteless; permanent in the air. Only slightly soluble in water, more readily in presence of hypophosphorous acid, or in a warm, concentrated solution of an alkali citrate, forming with the latter a green solution. When strongly heated in a dry test-tube, the salt evolves spontaneously inflammable hydrogen phosphide gas, and, on complete ignition, leaves a residue of ferric pyrophosphate. The salt is readily oxidized by nitric acid or other oxidizing agents. If to 0·5 Gm. of the salt 5 C.c. of acetic acid be added, no effervescence should occur (absence of *carbonate*), and if the mixture be subsequently heated to boiling, the filtrate, upon cooling, should afford no turbidity with ammonium oxalate test-solution (absence of *calcium*). If 0·5 Gm. of the salt be boiled

with 10 C.c. of potassium or sodium hydrate test-solution, a reddish-brown precipitate will be produced; and if to the filtrate from the latter, slightly acidulated with hydrochloric acid, magnesia mixture be added, and subsequently an excess of ammonia water, no crystalline precipitate should be produced (absence of *phosphate*). If 0·1 Gm. of Ferric Hypophosphite be mixed with 10 C.c. of water, then 10 C.c. of diluted sulphuric acid and 50 C.c. of potassium permanganate decinormal volumetric solution added, and the mixture boiled for fifteen minutes, it should require not more than 3 C.c. of oxalic acid decinormal volumetric solution to discharge the red color (corresponding to at least 98·1 per cent. of the pure salt)." *U. S.*

Syrup of ferric hypophosphite may be prepared by simply adding syrup to the solution of the hypophosphite remaining after the separation of the calcium sulphate in the process of Mr. Wood above given. If two and a half ounces of water be used in the process, and the paste resulting from the precipitation of the calcium sulphate be pressed out, the remaining liquid, after filtration, will form with seven times its volume of syrup a liquid containing two grains of the hypophosphite in a fluidrachm. (*P. J. Tr.*, April, 1868.) But in this form, if the syrup be not thoroughly enclosed, it quickly absorbs oxygen, and in a few hours begins to exhibit the formation of a precipitate, rendering it in a short time unfit for use. A little phosphoric or citric acid added to the syrup will obviate this result; but it is better perhaps at once to form a syrup from materials which will not be liable to this objection. Mr. Wood employs the following process. "Take of granulated ferrous sulphate 480 gr., calcium hypophosphite 326 gr., diluted phosphoric acid f ʒi, water f ʒiss, syrup q. s. Dissolve, without heat, the ferrous sulphate in the phosphoric acid, previously mixed with the water. Rub the hypophosphite to fine powder, and pour on it the solution of the sulphate. Triturate together for two or three minutes, then pour the mixture on a piece of damp calico, and squeeze out the liquid with the hands. Filter this solution, and add to it seven times its volume of strong syrup. The resulting syrup will contain two grains of ferric hypophosphite in each fluidrachm." The dose may be from two to six fluidrachms (7·5–22·50 C.c.).

Prof. C. L. Diehl prepares the syrup from a freshly precipitated magma produced by precipitating a solution of calcium hypophosphite with solution of ferric chloride and dissolving the magma by the aid of potassium citrate. (*Proc. A. P. A.*, 1882, 71; see, also, National Formulary, PART II.) Ferric hypophosphite may be given in states of the system where deficient powers of the cerebral centres are attended with an anæmic condition of the blood. It may be administered in pill or in powder in the dose of from five to ten grains (0·324–0·648 Gm.); but a more eligible form, and one generally preferred, is that of syrup.

FERRI IODIDUM SACCHARATUM. U. S. Saccharated Ferrous Iodide.

(FĔR'RĪ Ī-ŌD'Ị-DŬM SĂC-ȼHẠ-RĀ'TŬM.)

Saccharated Iodide of Iron; Ferrum Iodatum Saccharatum, *P. G.*; Zuckerhaltiges Jodeisen, *G.*

"Iron, in the form of fine, bright wire, and cut into small pieces, *six grammes* [or 92 grains]; Reduced Iron, *one gramme* [or 15·5 grains]; Iodine, *seventeen grammes* [or 262 grains]; Distilled Water, Sugar of Milk, recently dried, each, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 231 grains]. Mix the Iron Wire, Iodine, and *twenty cubic centimeters* [or 325 minims] of Distilled Water in a flask of thin glass, shake the mixture occasionally, until the reaction ceases, and the solution has acquired a green color and lost the smell of Iodine; then filter it through a small, wetted filter into a porcelain capsule containing *forty grammes* [or 1 ounce av., 180 grains] of Sugar of Milk. Rinse the flask and Iron Wire with a little Distilled Water, pass the rinsings through the filter into the capsule, and evaporate, on a water-bath, with frequent stirring, until a dry mass remains. Transfer this quickly to a heated iron mortar, reduce it to powder, and mix it intimately, by trituration, with the Reduced Iron and enough Sugar of Milk to make the final product weigh *one hundred grammes* [or 3 ounces av., 231 grains]. Transfer the powder at once to small and perfectly dry bottles, which should be securely stoppered, and kept in a cool and dark place." *U. S.*

This official preparation is practically identical with the Saccharated Iodide of Iron of the German Pharmacopœia, and consists of ferrous iodide preserved by contact with sugar of milk. It is a more stable form of administering ferrous iodide than the salt in its pure state. (See *Ferri Iodidum.*)* The addition of reduced iron to the preparation just before the close

* *Tasteless Salts of Iron.* A class of preparations of iron has been introduced by Mr. J. L. A. Creuse (*A. J. P.*, xlv. 214). It has long been known that ammonium citrate has the property of rendering soluble many ordinarily insoluble preparations of iron. Mr. Creuse believes that all the salts of ferric oxide form chemical combi-

of the process is for the purpose of protecting it from change: any iodine which may be set free through exposure will combine with the reduced iron, and thus the irritating effects of free iodine will be avoided.

Properties. The Pharmacopœia gives the following description: "A yellowish-white or grayish, very hygroscopic powder, without odor, and having a sweetish, ferruginous taste. Soluble (with exception of the added reduced iron) in 7 parts of water at 15° C. (59° F.), but only partially soluble in alcohol. When strongly heated, the compound swells up, evolves the odor of iodine and of burning sugar, and, on complete ignition, leaves a residue which should yield nothing soluble to water (absence of *salts of the fixed alkalies*). The aqueous solution has a slightly acid reaction, and gives with potassium ferricyanide test-solution a blue precipitate. If the aqueous solution be mixed with a little starch test-solution, and afterwards with a few drops of chlorine water, it will assume a deep blue color. This color should not be developed in the aqueous solution by starch test-solution alone (absence of *free iodine*). If 1·55 (1·5447) Gm. of Saccharated Ferrous Iodide be dissolved in about 20 C.c. of water, in a small flask, and to this solution be successively added, first, 22 C.c. of silver nitrate decinormal volumetric solution, then 5 C.c. of diluted nitric acid and 5 C.c. of ferric ammonium sulphate test-solution, it should not require more than 2 C.c. of potassium sulphocyanate decinormal volumetric solution to produce a reddish-brown tint which persists after shaking (corresponding to about 20 per cent. of pure Ferrous Iodide)." *U. S.*

Medical Properties. The medical properties of this preparation are identical with those of ferrous iodide. The dose is from two to five grains (0·13 to 0·33 Gm.).

FERRI LACTAS. U. S. Ferrous Lactate.

$Fe(C_3H_5O_3)_2 . 3H_2O$; 287·34. (FĔR'RĪ LĂC'TĂS.) $Fe(C_3H_5O_3)_2 . 3H_2O$; 287·9.

Lactate of Iron; Ferrum Lacticum, *P. G.;* Lactas Ferrosus; Lactate de Fer, *Fr.;* Milchsaures Eisenoxydul, Eisenlactat, *G.*

"Ferrous Lactate should be kept in well-stoppered bottles." *U. S.*

A formula for this salt was omitted in the 1880 U. S. P. revision. In the process of the U. S. P. 1870* the lactic acid unites with the iron, forming ferrous lactate, a part of which crystallizes when the solution cools, and the remainder is obtained by evaporation and crystallization. It may be more cheaply prepared, on the large scale, by digesting the impure acid first obtained in M. Louradour's process, with iron filings, or by reaction between ferrous sulphate and the calcium lactate or zinc lactate prepared as a step in obtaining lactic acid. The following is M. Gobley's process for making calcium lactate preparatory to its conversion into ferrous lactate. Add to 2 pints of skim-milk, diluted with twice its bulk of water, and contained in an earthen pan, 64 drachms of powdered lactose, and 51 drachms of powdered chalk. Allow the whole to ferment for eleven or twelve days, at a temperature of from 26·6° to 32·2° C. (80° to 90° F.), supplying water as it evaporates. Transfer the liquor to a capsule, heat it gradually to boiling, and stir it constantly. Boil for a quarter of an hour to coagulate casein, allow the insoluble matters to subside, and strain the liquid through flannel. The clear liquid is a solution of cal-

nations with all the alkaline (ammonium, sodium, potassium, lithium) citrates, which combinations are all greenish, soluble in water, nearly insoluble in alcohol, free from ferruginous taste, perfectly stable, and so resist decomposition as to form no precipitate with Peruvian bark; indeed, chemical reagents do not reveal the iron in them unless strong acids of hydrogen sulphide be used. None of these salts coagulate the blood; they cannot be used as styptics.

Tasteless Iron Iodide is prepared in the following manner: 126·3 grains of iodine are combined with iron in the usual way to obtain the solution of ferrous iodide; this is filtered and 63 grains of iodine dissolved in it; a solution of 201 grains of citric acid is exactly saturated with potassa and then added gradually to the first solution. When the apple-green color has been developed, the solution is evaporated, with gentle stirring, to dryness, when cauliflower-like masses of acicular crystals will be obtained. These are stable except in direct sunlight. (See *Syrupus Ferri Citro-Iodidi,* National Formulary, PART II.)

Tasteless Iron Chloride is made by adding an alkaline citrate in solution to a solution of iron sesquichloride, in such proportion that there shall be two molecules of the former to three molecules of chlorine. Usually from 120 to 140 grains of citric acid saturated with soda, potassa, or ammonia are required for the preparation of an ounce of a tincture of corresponding strength to the official tincture. The addition should be made to the liquor, and the final solution must not contain more than 40 per cent. of alcohol. R. Rother affirms that these so-called salts are mere mixtures of iron citrate and iodide or chloride of the alkali used. (*A. J. P.,* 1876, p. 171; see, also, *Syrupus Ferri Protochloridi,* National Formulary, PART II.)

* "Take of Lactic Acid *a fluidounce;* Iron, in the form of filings, *half a troyounce;* Distilled Water *a sufficient quantity.* Mix the Acid with a pint of Distilled Water in an iron vessel, add the Iron, and digest the mixture on a water-bath, supplying Distilled Water, from time to time, to preserve the measure. When the action has ceased, filter the solution, while hot, into a porcelain capsule, and set it aside to crystallize. At the end of forty-eight hours, decant the liquid, wash the crystals with a little alcohol, and dry them on bibulous paper. By evaporating the mother-water in an iron vessel to one-half, filtering while hot, and setting the liquid aside, more crystals may be obtained." *U. S.* 1870.

cium lactate. In this process the casein of the milk, acting as a ferment, converts not only the lactose of the milk, but the lactose added, into lactic acid; a result which would not take place were it not for the presence of the chalk, which saturates the lactic acid as it is formed, and prevents it from uniting with the casein, whereby the power of the latter as a ferment would be destroyed. (*Journ. de Pharm.*, 3e sér., vi. 54.) (See, also, other methods under *Acidum Lacticum*, p. 65.) Calcium lactate may be expeditiously converted into iron lactate by the following process of M. Lepage. Dissolve 100 parts of calcium lactate, obtained by M. Gobley's process, in 500 parts of boiling water; dissolve also 68 parts of pure crystallized ferrous sulphate in 500 parts of cold distilled water. Mix the filtered solutions in a matrass, acidulate slightly with lactic acid, and heat in a water-bath, stirring frequently until the double decomposition is completed. Then filter to separate the calcium sulphate, and evaporate rapidly to one-half, either in an iron vessel, or in a porcelain capsule containing a few turnings of iron. Filter again, and set aside to crystallize; and, having washed the crystals in a funnel with a little alcohol, dry them on bibulous paper. (*Journ. de Pharm.*, 3e sér., ix. 272.) In relation to the precautions to be observed in preparing this lactate, so as to prevent the partial oxidation of the iron, see *A. J. P.*, 1853, p. 556.*

Ferrous lactate is in "pale greenish-white crusts, consisting of small, needle-shaped crystals, having a slight, peculiar odor, and a mild, sweetish, ferruginous taste. Slowly but completely soluble in 40 parts of water at 15° C. (59° F.), and in 12 parts of boiling water; freely soluble in a solution of an alkali citrate, yielding a green solution; almost insoluble in alcohol. When strongly heated, the salt froths up, gives out dense, white, acrid fumes, chars, and finally leaves a brownish-red residue. The aqueous solution of the salt has a greenish-yellow color, a slightly acid reaction, and gives with potassium ferricyanide test-solution a deep blue, and with potassium ferrocyanide test-solution a light blue, precipitate. A 2-per-cent. aqueous solution of the salt should not afford with lead acetate test-solution, nor, after acidulation with hydrochloric acid, with hydrogen sulphide test-solution, more than a whitish opalescence (limit or absence of *sulphate*, *chloride*, *citrate*, *tartrate*, *malate*, etc., and of *foreign metals*). The aqueous solution, acidulated with nitric acid, should not afford more than a slight opalescence with barium chloride test-solution, or with silver nitrate test-solution (limit of *sulphate* or *chloride*). If 25 C.c. of the aqueous solution (1 in 50), mixed with 5 C.c. of diluted sulphuric acid, be boiled for a few minutes, then precipitated by an excess of potassium or sodium hydrate test-solution, the filtrate, mixed with a few drops of alkaline cupric tartrate volumetric solution, and heated to boiling, should not afford a red precipitate (absence of *sugar*). If a portion of the salt be triturated with strong sulphuric acid, no offensive odor should be developed (absence of *butyric acid*), nor should any gas be evolved (absence of *carbonate*), and the mixture, after standing for some time, should not assume a brown color (absence of *sugar*, *gum*, or other *readily carbonizable impurities*). If 1 Gm. of the salt, contained in a porcelain crucible, be moistened with nitric acid, and carefully ignited, it should leave a residue of ferric oxide weighing not less than 0·270 nor more than 0·278 Gm. This residue should not have an alkaline reaction upon litmus paper, nor yield anything soluble to water (absence of *foreign salts*)." *U. S.* Ferrous lactate has an acid reaction. The aqueous solution quickly becomes yellow, in consequence of the iron passing to a higher state of oxidation. M. Louradour has seen several samples of this lactate variously adulterated, as with effloresced ferrous sulphate, starch, and lactin, the sophistication being concealed by the sale of the salt in powder. These impurities may be detected by appropriate reagents; but M. Louradour recommends the rejection of the salt when it is not in crystalline crusts.

Medical Properties. Ferrous lactate has the general medical properties of the ferruginous preparations, and has been especially used in chlorosis by Andral, Fouquier, Bouillaud, and other Parisian doctors. As much as twelve or even twenty grains (0·8–1·3 Gm.) may be given in the course of a day. It may be administered in lozenge, pill, or syrup. The *lozenge* may be made of one grain (0·065 Gm.) of the lactate to twelve grains (0·8 Gm.) of sugar; the *pill*, of one grain (0·065 Gm.) of the salt, with an equal weight of some inert powder free from astringent matter, and sufficient honey. The following is the formula for a *syrup* proposed by

* *Ferric Lactate.* Instead of the official ferrous lactate, Louis P. Carbonell recommends the ferric lactate, which he succeeded in obtaining in light-brown transparent scales by following the process for the other scale preparations of iron, taking particular care fully to saturate the acid and to avoid high temperature during the whole operation. If the first precaution be overlooked, a more or less pasty mass will be the result, and if the temperature rise too high a pulverulent salt will be obtained. The scaled salt is freely soluble in water and alcohol.

Iron and quinine lactate and *iron and strychnine lactate* may also be obtained in brown scales, have a bitter ferruginous taste, and are soluble in alcohol and water. (*A. J. P.*, 1876, p. 489.)

M. Cap. Take of ferrous lactate *a drachm;* white sugar *twelve ounces and a half;* boiling distilled water *six fluidounces and a half.* Rub the salt to powder with half an ounce of the sugar, and dissolve the mixture quickly in the boiling water. Pour the solution into a matrass placed on a sand-bath, and add to it the rest of the sugar in small pieces. When the sugar is dissolved, filter the syrup, and, as soon as it is cold, transfer it to bottles, which must be well stopped. This syrup has a very light amber color, and contains about four grains of the salt to the fluidounce. The dose is from two to four fluidrachms (7·5–15 C.c.). Bread, called *chalybeate bread*, containing ferrous lactate in the proportion of about a grain (0·065 Gm.) to the ounce (31·1 Gm.), has been used with advantage by chlorotic patients in one of the hospitals of Paris. The bread is not injured in taste or quality.

FERRI OXIDUM HYDRATUM. U. S. Ferric Hydrate.

[Ferric Hydroxide. Hydrated Oxide of Iron.]

$Fe_2(OH)_6$; 213·52. (FĔR′RĪ ŎX′Ĭ-DŬM HĪ-DRĀ′TŬM.) $Fe_2(HO)_6$; 213·8.

Ferri Sesquioxidum; Ferri Oxidum Rubrum; Hydrous Peroxide of Iron; Ferric Oxyhydrate; Ferrugo; Hydrated Peroxide of Iron, Hydrated Sesquioxide of Iron, Moist Peroxide of Iron; Hydras Ferricus: Sesquioxide (Péroxide) de Fer hydraté humide, Hydrate de Péroxyde de Fer gélatineux, *Fr.;* Feuchtes Eisenoxydhydrat, Gegengift der Arsenigensäure, *G.*

"Solution of Ferric Sulphate, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Ammonia Water, *one hundred and ten cubic centimeters* [or 3 fluidounces, 345 minims]; Water, *a sufficient quantity.* To the Ammonia Water, previously diluted with *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of cold Water, add, under constant stirring, the Solution of Ferric Sulphate, previously diluted with *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of cold Water. As soon as the precipitate has subsided, draw off the clear liquid by means of a siphon, then mix the precipitate intimately with about *one thousand cubic centimeters* [or 33 fluidounces, 390 minims] of cold Water, again draw off the clear liquid after subsidence of the precipitate, and repeat this operation, until a portion of the decanted liquid gives not more than a slight cloudiness with barium chloride test-solution. Finally transfer the precipitate to a wet muslin strainer, and, after it has drained, mix it with sufficient cold Water to make the mixture weigh *two hundred and fifty grammes* [or 8 ounces av., 358 grains]. When Ferric Hydrate is to be made in haste, for use as an antidote, the washing may be performed more quickly, though less perfectly, by transferring the precipitate at once to a wet muslin strainer, pressing forcibly with the hands, until no more liquid passes, and then adding enough Water to make the whole weigh about *two hundred and fifty grammes* [or 8 ounces av., 358 grains.]

"*Note.*—The ingredients for preparing Ferric Hydrate as an antidote should always be kept on hand in bottles containing, respectively, *two hundred cubic centimeters* [or 6 fluidounces, 366 minims] of the Solution of Ferric Sulphate, and *two hundred and twenty cubic centimeters* [or 7 fluidounces, 210 minims] of Ammonia Water." *U. S.*

This preparation was introduced into the U. S. Pharmacopœia on account of its importance as an antidote to arsenous acid. It is frequently used in the official processes as the source of iron when it is desired to produce a ferric compound, but the directions for making it always accompany the preparation in which it is used, because of the difficulty of preserving the ferric hydrate. In the former processes the first step was to convert ferrous sulphate into ferric sulphate; but in the present the official solution of ferric sulphate is taken already containing the iron in the proper state of oxidation. This is simply treated with ammonia water (*U. S.*), which throws down the oxide combined with water, constituting the hydrated oxide required.

It is the duty of the apothecary to be always prepared to make this antidote, by keeping the necessary solutions for its precipitation. Magnesia is probably a better precipitant than either of those official. (See next article.) In most cases of arsenical poisoning, minutes are of immense importance, and time must be lost in washing the precipitated iron if the official process be adhered to. Magnesia is not only not irritant, but is itself antidotal to arsenic: so that the precipitated mass may be given at once to the patient. The oxide should not be kept in stock, but when ordered as an antidote should be made fresh.

The British Pharmacopœia (1898) no longer includes ferric hydrate. This is to be regretted, for, although not a stable preparation, an official process to be used in the emergency arising from arsenical poison should be quickly available; in our opinion every Pharmacopœia should contain an official antidote to arsenic.

Properties. Ferric hydrate, as directed by the U. S. formula, "is a brownish-red magma, wholly soluble in hydrochloric acid without effervescence." As prepared by the Dublin pro-

cess, in which it was heated to redness, it lost the second molecule of water, and became the anhydrous sesquioxide (Fe_2O_3), identical with the *colcothar* of commerce.

The monohydrated sesquioxide is a reddish-brown, tasteless, insoluble powder, differing from colcothar in containing a molecule of water. Hence, "heated to dull redness in a test-tube it yields about 10 per cent. of moisture." *Br.* (1885). It should not be deliquescent, and should dissolve entirely in hydrochloric acid without effervescence. Its solution in diluted hydrochloric acid yields a copious blue precipitate with potassium ferrocyanide, but none with the ferricyanide, showing that it contains ferric oxide but no ferrous oxide. If it contain copper, its hydrochloric solution will deposit this metal on a bright piece of iron. M. Dawies states that if the hydrated oxide recently prepared be kept for four or five days in boiling water it loses a large proportion of its water, containing at the end of that time only 5·77 per cent.; the larger portion of the oxide has, therefore, become dehydrated; and the same thing happens at a lower temperature, 41·1° C. (106° F.), in two or three months: it becomes of a brick-red color, and is but slightly soluble in nitric acid. (*Journ. de Pharm.*, 4e sér., iv. 400.) This oxide is not used as a medicine. It is employed in making iron plaster and reduced iron, for which purposes other forms of oxidized iron would answer as well. The former Dublin *rubigo ferri*, or *rust of iron*, formed by exposing moistened iron wire to the air till converted into rust, is essentially the sesquioxide, containing a little ferric carbonate, and does not differ materially from the iron subcarbonate formerly official.*

If exposed to a red heat it loses the combined water, and becomes the anhydrous sesquioxide, less easily soluble in acids, improper for medical use, and altogether without effect as an antidote. Kept for some time in the pulpy state, it loses half its combined water, and becomes less soluble in acids and less efficient as an antidote. Dr. Hirsch has given some useful details in making precipitated ferric oxide upon a comparatively large scale, in *Amer. Drug.*, 1884, 66.

Medical Properties and Uses. Ferric hydrate is not an eligible ferruginous preparation for medical use. Its antidotal powers in poisoning by arsenic, the manner in which it acts, the circumstances which impair its efficiency, and the mode of using it, are fully explained under *Acidum Arsenosum*. Its power of rendering arsenous acid insoluble is readily shown by agitating a solution of the acid with a considerable excess of the moist oxide, filtering, and then testing the filtered solution for the acid: not a trace of the metal can be detected, even by hydrogen sulphide. It is stated, however, to be inferior as an antidote to the saccharated oxide. Ferric hydrate as obtained by the U. S. formula contains a little ammonia, which is thought by some to assist its antidotal powers. At least it has been ascertained that the sesquioxide when precipitated by potassa, as formerly directed by the Dublin College, is less efficient than when precipitated by ammonia, and must be employed in quantities three or four times as large to produce the same effect. The dry hydrate rubbed up with water is in the same proportion weaker than the pulpy hydrate. Ferric carbonate (formerly official) possesses

* *Ferri Subcarbonas*, U. S. 1870; *Subcarbonate of Iron; Sesquioxide of Iron; Red Oxide of Iron; Precipitated Carbonate of Iron; Aperitive Saffron of Mars.* "Take of Sulphate of Iron *eight troyounces*; Carbonate of Sodium *nine troyounces*; Water *eight pints*. Dissolve the salts separately, each in four pints of the Water; then mix the solutions thoroughly, and set aside the mixture until the precipitate has subsided. Then pour off the supernatant liquid, wash the precipitate with water until the washings pass nearly tasteless, and dry it on bibulous paper without heat." *U. S.* 1870.

When the solutions of sodium carbonate and ferrous sulphate are mixed together, a hydrated ferrous carbonate, of a pale-blue color, is thrown down, and sodium sulphate remains in solution. The precipitate during the washing and drying absorbs oxygen and loses nearly all its carbonic acid, whereby it is converted almost entirely into ferric oxide. The direction to dry the precipitate without heat is important, as even a moderate elevation of temperature has been shown by the experiments of Mr. J. A. Rex to modify the resulting product unfavorably, diminishing its solubility in hydrochloric acid in proportion to the heat employed. (*A. J. P.*, May 1862, p. 193.)

Properties. Ferric carbonate is a reddish-brown powder, of a disagreeable, slightly styptic taste, insoluble in water, and not readily dissolved by any acid except hydrochloric, with which it effervesces slightly. When of a bright-red color it should be rejected, as this color shows that it has been injured by exposure to heat. After precipitation from its hydrochloric solution by ammonia or potassa, either of which throws down ferric oxide, the supernatant liquor should give no indications of containing any metal in solution by the test of hydrogen sulphide or potassium ferrocyanide. It is incompatible with acids and acidulous salts. In composition it is a hydrated ferric oxide containing a little ferrous carbonate. By exposure to a red heat, it absorbs oxygen and loses water and carbonic acid, being converted into the *astringent saffron of Mars* of the French Codex. After ignition it is no longer a subcarbonate, but is converted into the pure sesquioxide, which is less soluble in acids and less efficient as a medicine than the preparation in its original state. Hence it is wrong to expose the subcarbonate to a red heat, as some manufacturing chemists are in the habit of doing in order to give it a bright-red color.

Medical Properties and Uses. Ferric carbonate is a rather feeble ferruginous tonic, nearly free from astringency, and causing, even in the largest doses, no obvious effects save a very slight gastric disturbance. It has been especially commended in neuralgia in doses of a teaspoonful (3·75 C.c.). Dose, five grains (0·33 Gm.).

antidotal powers to arsenic, though in an inferior degree; but this statement will not apply to it after it has been exposed to a red heat, to which it is improperly subjected by some manufacturing chemists. By ignition it becomes anhydrous, and altogether inefficient as an antidote.

FERRI OXIDUM HYDRATUM CUM MAGNESIA. U. S. Ferric Hydrate with Magnesia. [Arsenic Antidote.]

(FĔR'RĪ ŎX'Ĭ-DŬM HĬ-DRĀ'TŬM CŬM MĂG-NĒ'ŞĬ-Ą.)

Antidotum Arsenici, *P. G.;* Antidote to Arsenious Acid; Hydrated Oxide of Iron with Magnesia; Gegengift der Arsenigensäure, *G.*

"Solution of Ferric Sulphate, *fifty cubic centimeters* [or 1 fluidounce, 331 minims]; Magnesia, *ten grammes* [or 154 grains]; Water, *a sufficient quantity.* Mix the Solution of Ferric Sulphate with *one hundred cubic centimeters* [or 3 fluidounces, 183 minims] of Water, and keep the liquid in a large, well-stoppered bottle. Rub the Magnesia with cold Water to a smooth and thin mixture, transfer this to a bottle capable of holding about *one thousand cubic centimeters* [or 33 fluidounces, 390 minims], and fill it with Water to about three-fourths of its capacity. When the preparation is wanted for use, shake the Magnesia mixture to a homogeneous, thin magma, gradually add to it the Iron Solution, and shake them together until a uniform, smooth mixture results.

"*Note.*—The diluted Solution of Ferric Sulphate, and the mixture of Magnesia with Water, should always be kept on hand, ready for immediate use." *U. S.*

This is a preparation which has been introduced for the purpose of furnishing a ready and efficient antidote against arsenous acid. It is almost identical with the *Antidotum Arsenici* of the German Pharmacopœia, and experience has shown its effectiveness. Ferric hydrate is produced when the mixture of magnesia is added to the diluted solution of ferric sulphate, and, as the magnesia is in excess and acidity thus prevented, no harm can result from not separating the by-products of the reaction. When mixed as officially directed, and ready for use, it contains ferric hydrate with magnesium sulphate and hydrate. It has been shown that no soluble compound with arsenic is formed when it is used as an antidote, and the presence of the magnesium salts, from a therapeutical point of view, is not at all objectionable. (See *Acidum Arsenosum*, p. 19.)

FERRI PHOSPHAS. Br. Iron Phosphate.

(FĔR'RĪ PHŎS'PHĂS.)

"A powder containing not less than 47 per cent. of hydrous ferrous phosphate, $Fe_3(PO_4)_2 8H_2O$, with ferric phosphate and some iron oxide." *Br.*

Phosphate of Iron; Ferrum Phosphoricum, *P.G.;* Phosphas Ferroso-Ferricus; Ferroso-Ferric Phosphate; Phosphate de Fer, Phosphate ferroso-ferrique, *Fr.;* Phosphorsaures Eisenoxydul (Eisenoxydul-Oxyd), *G.*

"Ferrous Sulphate, 3 *ounces* (Imperial) or 60 grammes; Sodium Phosphate, 2¾ *ounces* (Imp.) or 55 grammes; Sodium Bicarbonate, ¾ *ounce* (Imp.) or 15 grammes; Distilled Water, boiling, *a sufficient quantity.* Dissolve the Ferrous Sulphate in *thirty fluid ounces* (Imp. meas.) or six hundred cubic centimetres of the Distilled Water, and the Sodium Phosphate in an equal quantity of Distilled Water; when each of the solutions has cooled to between 100° and 130° F. (37·8° and 54·4° C.), add the latter to the former, pouring in also a solution of the Sodium Bicarbonate in a little Distilled Water; mix thoroughly; transfer the precipitate to a calico filter; wash it with hot Distilled Water until the washings no longer afford any reaction with the tests for sulphates; finally dry the precipitate at a temperature not exceeding 120° F. (48·9° C.)." *Br.*

The title of the U. S. salt has been changed in the U. S. P. (1890) by the addition of the word "Solubilis:" this action should have been taken in 1880, for reasons set forth in the 16th ed. U. S. D. Considerable confusion has been caused in the past through mistaking the insoluble slate-colored ferric phosphate for the official scaled salt, which is soluble (see page 627). As obtained by the present process, the U. S. salt is not a definite chemical compound, but a mixture, which should probably be called sodio-ferric citro-phosphate, and bears a resemblance to the pyrophosphate, which is now directed to be made by a similar process. (See *Ferri Pyrophosphas.*)

The British iron phosphate is a very different salt. By double decomposition ferrous phosphate and sodium sulphate are produced, the former precipitating as a white bulky powder, which soon changes on exposure to a greenish-blue, and ultimately to a slate color; a portion of sulphuric acid is liberated from the ferrous sulphate during the reaction, and this, retaining in solution some of the ferrous phosphate, requires the addition of the solution of sodium

bicarbonate to decompose it and set free the remainder of the ferrous phosphate. This salt, when first formed, is represented by the formula $Fe_3(PO_4)_2$; but the strong affinity of its ferrous oxide for oxygen causes the gradual production of sesquisalt, which, therefore, to a certain extent, always exists in the preparation; hence the British authority requires it to contain at least 47 per cent. of ferrous phosphate, $Fe_3(PO_4)_2 8H_2O$. (See *P. J. Tr.*, 1897, 141.)

Ferric phosphate, as made by the U. S. Pharmacopœia, is in "thin, bright green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air when excluded from light, but becomes dark and discolored on exposure to light. Freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt has a slightly acid reaction. With potassium ferrocyanide test-solution it gives a blue color, but does not yield a blue precipitate, unless it has been acidulated with hydrochloric acid. If 1 Gm. of the salt be boiled with 10 C.c. of potassium or sodium hydrate test-solution, a reddish-brown precipitate will be produced, and if the colorless filtrate from this precipitate be strongly acidulated with hydrochloric acid, then magnesia mixture added, and subsequently a slight excess of ammonia water, an abundant, white, crystalline precipitate will be produced. If a portion of the filtrate from this precipitate be acidulated with acetic acid, and heated to boiling, no further precipitate should be produced (absence of *pyrophosphate*). If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 15 C.c. of water and 2 C.c. of hydrochloric acid, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 12 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.* When made by the British process, it is in the form of "A slate-blue amorphous powder, insoluble in *water*, soluble in *hydrochloric acid*. The solution yields a precipitate with *solutions of potassium ferrocyanide* and *ferricyanide;* and when treated with *tartaric acid* and an excess of *solution of ammonia*, and subsequently with the *solution of magnesium ammonio-sulphate*, it gives a white granular precipitate. Each gramme dissolved in *hydrochloric acid* should not cease to yield a blue precipitate with *solution of potassium ferricyanide* until at least 28·2 cubic centimetres of the *volumetric solution of potassium bichromate* have been added. It should yield no characteristic reaction with the tests for arsenium." This shows the presence of 47 per cent. of ferrous phosphate.

Ferric phosphate, dissolved to saturation in a boiling solution of metaphosphoric acid (HPO_3), under the name of *superphosphate of iron*, was proposed as a new remedy, in January, 1851, by Dr. Routh, of London. Mr. Thomas Greenish, of the same city, states that the solution of the salt, on cooling, hardens into a mass of pilular consistence, soluble in water in all proportions, and free from any disagreeable or inky taste.

Medical Properties. Ferric phosphate possesses the general properties of the ferruginous preparations, and has been given with advantage in amenorrhœa and dyspepsia. The dose is from five to ten grains (0·33–0·65 Gm.).*

* *Compound Syrup of Phosphate of Iron. Chemical Food.* For a formula for a compound syrup of phosphate of iron by Mr. Wiegand, made by introducing into it the phosphates of calcium, potassium, and sodium, and for remarks on the pharmacy of the phosphates by Prof. Procter, see *A. J. P.*, 1854 (pp. 111 and 112). A formula similar to Mr. Wiegand's, communicated by Mr. Edward Parrish as probably representing the process for a secret preparation considerably used in this city, may be found in *A. J. P.*, 1857 (p. 573). These formulas are too complicated to have any therapeutic value. Nevertheless, as the preparations have had much vogue, under the name of *chemical food*, we give the formula of Mr. Parrish from the journal referred to. "Take of Sulphate of Iron ℥x; Phosphate of Soda ℥xii; Phosphate of Lime ℥xii; Glacial Phosphoric Acid ℥xx; Carbonate of Soda ℈ij; Carbonate of Potassa ℥i; Hydrochloric Acid, Water of Ammonia, each, q. s.; Powdered Cochineal ℥ij; Water q. s. to make f℥xx; Sugar ℔iij (troy); Oil of Orange ♏x. Dissolve the Sulphate of Iron in f℥ij and the Phosphate of Soda in f℥iv of boiling Water. Mix the solutions, and wash the precipitated phosphate of iron till the washings are tasteless. Dissolve the Phosphate of Lime in f℥iv of boiling Water with sufficient Hydrochloric Acid to make a clear solution, precipitate it with Water of Ammonia, and wash the precipitate. To the freshly precipitated phosphates add the Phosphoric Acid previously dissolved in Water. When clear, add the Carbonates of Soda and Potassa, and afterwards sufficient Hydrochloric Acid to dissolve the precipitate. Now add Cochineal mixed with the Sugar, apply heat, and, when the syrup is formed, strain and flavor it. Each teaspoonful contains about one grain of phosphate of iron and two and a half grains of phosphate of lime, with smaller quantities of the alkaline phosphates, all in perfect solution." The objection to such preparations as this is not that each of the ingredients may not be useful, but that they are so numerous that a morbid state of system in which they can all be indicated must be extremely rare, and every medicine is more or less noxious if given when it is not needed. The probability is that the therapeutic value of the preparation depends mainly on its ferruginous ingredient, and that, as a rule, its therapeutic effects may be equally well if not better obtained from a simple syrup of ferric phosphate. (See *P. J. Tr.*, 1893, 795, 797.)

FERRI PHOSPHAS SOLUBILIS. U. S. Soluble Ferric Phosphate.

(FĔR'RĪ PHŎS'PHĂS SO-LŪ'BĬ-LĬS.)

Ferri Phosphas, *U. S.* 1880.

" Ferric Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Phosphate, unefflouresced, *fifty-five grammes* [or 1 ounce av., 411 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Ferric Citrate in the Distilled Water by heating on a water-bath. To this solution add the Sodium Phosphate, and stir constantly until it is dissolved. Evaporate the solution on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.* (See preceding article.)*

FERRI PYROPHOSPHAS SOLUBILIS. U. S. Soluble Ferric Pyrophosphate.

(FĔR'RĪ PĪ-RO-PHŎS'PHĂS SO-LŪ'BĬ-LĬS.)

Ferri Pyrophosphas, *U. S.* 1880; Ferric Pyrophosphate; Pyrophosphate of Iron; Ferrum Pyrophosphoricum cum Ammonio Citrico, *P. G.*; Pyrophosphas Ferricus cum Citrate Ammonico; Pyrophosphate of Iron with Ammonium Citrate; Pyrophosphate de Fer citro-ammoniacal, *Fr.*; Pyrophosphorsaures Eisenoxyd mit Citronensauren Ammonium, *G.*

" Ferric Citrate, *fifty grammes* [or 1 ounce av., 334 grains]; Sodium Pyrophosphate, unefflouresced, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]. Dissolve the Ferric Citrate in the Distilled Water, by heating on a water-bath. To this solution add the Sodium Pyrophosphate, and stir constantly, until it is dissolved. Evaporate the solution, on a water-bath, at a temperature not exceeding 60° C. (140° F.), to the consistence of thick syrup, and spread it on plates of glass, so that, when dry, the salt may be obtained in scales. Keep the product in dark amber-colored, well-stoppered bottles." *U. S.*

There does not seem to be a good reason for appending "Solubilis" to the title of this salt: it is practically the same ferric pyrophosphate as that of the U. S. P. 1880, which had no such addition (see *Ferri Phosphas Solubilis*). The unnecessary lengthening of the official Latin names which must be used in prescription-writing is to be strongly deprecated. This formula is based upon a method proposed by M. E. Robiquet to the Academy of Medicine at Paris, in February, 1857, of preparing ferric pyrophosphate for use, by dissolving a gelatinous precipitate of the salt in a solution of ammonium citrate, and forming a syrup with the solution.†

The view which obtained when this process was first made official was that a double salt was formed, consisting of ferric pyrophosphate and ammonium citrate, which might be called ammonio-ferric citro-ortho phosphate. According to R. Rother (*A. J. P.*, 1876, p. 174), there was an excess of ferric citrate in the pyrophosphate of iron of the U. S. P. 1870, and it was believed to be a complex mixture of the colloid salts ammonio-ferric pyrophosphate, ammonio-ferric citrate, and free ferric citrate, as shown in the reaction $2(Fe_4 3P_2O_7) + 6(NH_4)_3C_6H_5O_7 =$

Simple Syrup of Phosphate of Iron. Subsequently Mr. Wiegand gave a formula for a simple syrup of phosphate of iron, made by dissolving the recently precipitated salt in hydrochloric acid and adding the requisite quantity of sugar. By a misprint the sodium phosphate taken is double what it should be. The same writer has proposed to make a syrup of the iron and calcium phosphates, by dissolving in the above a definite quantity of recently precipitated calcium phosphate, made by double decomposition between solutions of calcium chloride and sodium phosphate. See his formulas in *A. J. P.*, 1855 (p. 104).

* W. A. Puckner (*Proc. A. P. A.*, 1897, 231) proposes the following modification of the official process, preferring potassium chlorate to nitric acid as an oxidizing agent. Ferrous sulphate, in clear crystals, 156 Gm.; sulphuric acid, 20 C.c.; potassium chlorate, 12 Gm.; ammonia water, 340 C.c.; citric acid, 120 Gm.; sodium phosphate, unefflouresced, 200 Gm.; water, a sufficient quantity. Add the sulphuric acid to 240 C.c. of water, contained in a glass or porcelain vessel, to this add the ferrous sulphate, warm gently until all is dissolved, then add the potassium chlorate and continue the heat for one-half hour, or until a drop of the solution added to potassium ferricyanide test-solution no longer produces a distinct green or bluish-green color. Add this solution, slowly and with constant agitation, to the ammonia water contained in a suitable vessel; to this mixture add hot water, 4000 C.c., and allow to subside, and, after one-half hour, decant or siphon off the clear supernatant liquid. To the residue add 2000 C.c. of hot water, allow to subside, and decant; repeat this washing with six portions of hot water, allowing the last portion to subside for at least six hours or overnight. Decant or siphon off the clear liquid as closely as possible, then add to the remaining magma the citric acid and the sodium phosphate, warm gently until solution results, and then evaporate on a water-bath at a temperature not exceeding 60° C. until the solution weighs 500 Gm., and spread it on plates of glass, so that, when dry, the salt may be obtained in scales.

Solution Ferric Phosphate (50 per cent.). By evaporating the solution made by Puckner's method (see above) on a water-bath until it measures 500 C.c., a solution is made containing 50 per cent. of ferric phosphate. (*U. S. P.*)

† For these processes in detail, and Soubeiran's *Syrup of Pyrophosphate of Iron*, see U. S. D., 15th edition, page 682.

$Fe_4 3P_2O_7.3(NH_4)_4P_2O_7 + 2(FeC_6H_5O_7.(NH_4)_3C_6H_5O_7) + 2(FeC_6H_5O_7)$. By mixing two molecules of ferric citrate and one of ammonium pyrophosphate a compound analogous to the official preparation was obtained, containing the same proportion of ammonio-ferric pyrophosphate, but mixed with twice as much ammonio-ferric citrate and free ferric citrate. Rother's views were adopted by the Committee of Revision of 1880, as well as the salt which he recommended, in which ammonia was replaced by soda, because of the greater stability of the latter. Soluble Ferric Pyrophosphate consists probably of sodio-ferric pyrophosphate, sodio-ferric citrate, and free ferric citrate.

Sodio-ferric pyrophosphate, dried at 100° C., is considered by Flückiger (*Pharm. Chem.*, 2d ed., p. 607, 1888) to have the following composition: $Fe_4(P_2O_7)_3 + 3Na_4P_2O_7 + 14H_2O$.

Properties. "Thin, apple-green, transparent scales, without odor, and having an acidulous, slightly saline taste. The salt is permanent in dry air, when excluded from light, but becomes dark and discolored on exposure to light. Freely and completely soluble in water, but insoluble in alcohol. The aqueous solution of the salt has a slightly acid reaction. With potassium ferrocyanide test-solution it gives a blue color, but does not yield a blue precipitate, unless it has been acidulated with hydrochloric acid. If 1 Gm. of the salt be boiled with 10 C.c. of potassium or sodium hydrate test-solution, a reddish-brown precipitate will be produced, and if the colorless filtrate from this precipitate be strongly acidulated with hydrochloric acid, then magnesia mixture added, and subsequently a slight excess of ammonia water, no precipitate should be produced (distinction from and absence of *ferric phosphate*). If a portion of the filtrate be acidulated with acetic acid, and heated to boiling, an abundant, white, flocculent precipitate (pyrophosphate) will be produced. If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 10 C.c. of water, then 10 C.c. of hydrochloric acid and subsequently 40 C.c. of water added, and, after the addition of 1 Gm. of potassium iodide, the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled, and mixed with a few drops of starch test-solution, it should require about 10 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron.)" *U. S.*

Medical Properties. It is a very good chalybeate, mild yet efficient in its action on the system, without disagreeable taste, and, from its solubility, readily administered in any form that may be desirable, whether that of pill, simple solution in water,* or syrup. The dose is from two to five grains (0·13–0·33 Gm.).

FERRI SULPHAS. U. S., Br. Ferrous Sulphate.

$FeSO_4.7H_2O$; 277·42. (FĔR'RĪ SŬL'PHĂS.) $FeSO_4.7H_2O$; 277·9.

"Ferrous Sulphate, $FeSO_4,7H_2O$, may be prepared by the interaction of diluted sulphuric acid and iron." *Br.* "Ferrous Sulphate should be kept in well-stoppered bottles." *U. S.*

Sulphate of Iron, Green Vitriol; Ferrum Sulfuricum Purum, *P. G.;* Sulfas Ferrosus, Ferrum Vitriolatum Purum, Vitriolum Martis Purum; Ferrous Sulphate; Sulfate (Protosulfate) de Fer, Sulfate ferreux, *Fr.;* Schwefelsaures Eisenoxydul, *G.*

The British Pharmacopœia (1885) contained the following process for this salt:

"Take of Iron Wire *four ounces* [avoirdupois]; Sulphuric Acid *four fluidounces* [Imperial measure]; Distilled Water *one pint and a half* [Imp. meas.]. Pour the Water on the Iron placed in a porcelain dish, add the Sulphuric Acid, and, when the disengagement of gas has nearly ceased, boil for ten minutes. Filter now through paper, and, after the lapse of twenty-four hours, separate the crystals which have been deposited from the solution. Let these be dried on filtering paper placed on porous bricks, and preserved in a stoppered bottle."

The object of this process is to make a pure ferrous sulphate by direct combination. Sulphuric acid, in a concentrated state, acts but imperfectly on iron; but when diluted, a vigorous action takes place, the oxygen of the water converts the metal into an oxide, with which the sulphuric acid unites, and hydrogen is evolved. The theoretical quantities for mutual reaction are 56 of iron to 98 of acid. This proportion is one part of iron to one and three-quarters of acid. The British Council uses an excess of acid, the weight of acid taken being 7·38 avoirdupois ounces, instead of 7. An excess of iron, however, is desirable, as it tends to secure the

* *Liquor Ferri Pyrophosphatis.* A permanent solution may be made by Rother's process by dissolving 120 grains of iron pyrophosphate in five fluidrachms of water with the aid of heat, filtering whilst hot, mixing the filtrate with two fluidrachms of glycerin, and adding enough water through the filter to make one fluidounce. (*Drug. Circ.*, 1886, p. 99.)

production of a perfect ferrous sulphate. A process for this salt was given in the U. S. P. 1870, which was based upon the method of Bonsdorff. This chemist found that, when a perfect ferrous sulphate was formed in solution by heating dilute sulphuric acid with an excess of iron, it might be crystallized free from sesquioxide, provided a little excess of sulphuric acid were added to the liquid before filtration, in order to prevent the formation of any sesquioxide during the process; at the same time avoiding, as much as possible, the contact of the air. Hence the directions in the former U. S. formula to acidulate with sulphuric acid, to cause the funnel to touch the bottom of the receiving vessel, which avoids the dropping of the liquid through the air, and to cover the vessel containing the concentrated liquid when it is set aside to crystallize.

Properties. Ferrous sulphate is in the form of "large, pale bluish-green, monoclinic prisms, without odor, and having a saline, styptic taste. Efflorescent in dry air, and, on exposure to a moist atmosphere, rapidly absorbing oxygen, and becoming coated with brownish-yellow, basic, ferric sulphate. Soluble in 1·8 parts of water at 15° C. (59° F.), and in 0·3 part of boiling water; insoluble in alcohol. When slowly heated to 115° C. (239° F.), the crystals fall to powder, and lose 38·84 per cent. of their weight (6 molecules of water of crystallization). The aqueous solution of the salt has an acid reaction, and, even when highly diluted, gives with potassium ferricyanide test-solution a blue color or precipitate, and with barium chloride test-solution a white precipitate insoluble in hydrochloric acid. If 1 Gm. of the salt be dissolved in about 25 C.c. of water, the solution heated to boiling, oxidized with nitric acid, and then mixed with a slight excess of ammonia water, the filtrate from the reddish-brown precipitate should be colorless, and should not be affected by hydrogen sulphide test-solution (absence of *copper*, *zinc*, etc.). If another portion of the filtrate be evaporated to dryness, and then ignited, it should not leave more than a trace of residue (limit of *salts of the fixed alkalies*). If 1·39 (1·3871) Gm. of the salt be dissolved in about 25 C.c. of water, and the solution acidulated with sulphuric acid, not less than 50 C.c. of potassium permanganate decinormal volumetric solution should be required to impart to the liquid a permanent pink color (each C.c. of the volumetric solution indicating 2 per cent. of crystallized Ferrous Sulphate)." *U. S.* "In oblique rhombic prisms, of a pale bluish-green color and astringent taste; insoluble in *alcohol* (90 per cent.), soluble in less than 2 parts of cold *water* and giving a clear solution (absence of oxysulphate). It affords the reactions characteristic of ferrous salts and of sulphates. Each gramme dissolved in *water* acidulated with *sulphuric acid* should not cease to yield a blue precipitate with *solution of potassium ferricyanide* until 36 cubic centimetres of the *volumetric solution of potassium bichromate* have been added. It should yield no characteristic reaction with the tests for copper, zinc, potassium, sodium, or ammonium. Its solution in *water* should not give any precipitate with *hydrogen sulphide* (absence of ferric compounds, etc.)." *Br.* As prepared by Bonsdorff's method, ferrous sulphate is blue verging upon green. When it becomes more green than blue, or entirely green, an indication is afforded that it contains some sesquioxide. By exposure to the air the crystals absorb oxygen, and become first green, and ultimately covered with a yellow efflorescence of subsulphate, insoluble in water. Sometimes the crystals are quite permanent when made by Bonsdorff's method, owing to the slight excess of acid which they contain. The aqueous solution is bluish green; but by standing it attracts oxygen, and becomes first green and then reddish, depositing, in the mean time, a portion of sesquisulphate, having the composition $Fe_2(SO_4)_3 + Fe_2O_3 + 8H_2O$. (Wittstein, *Chem. Gaz.*, May 15, 1849; from *Buchner's Repert.*) At a red heat it loses its acid, and is converted into the anhydrous ferric oxide called *colcothar*. It is incompatible with the alkalies and their carbonates, soaps, lime water, calcium and barium chlorides, sodium borate and phosphate, silver nitrate, and lead acetate and subacetate. It is decomposed also by astringent vegetable infusions, the tannic and gallic acids of which form, if any sesquioxide be present, a black compound of the nature of ink. The extent to which this change lessens the activity of the salt is not well ascertained. Ferrous sulphate, as found in commerce, is often the impure commercial sulphate, which is not fit for medicinal use.* The perfectly pure salt is precipitated

* *Commercial Ferrous Sulphate. Copperas.* This was formerly official in the London Pharmacopœia, in which it was employed for preparing the pure sulphate. It is manufactured on a large scale for the purposes of the arts, from the native ferric sulphide, or iron pyrites, by roasting, oxidation by exposure to air and moisture, and lixiviation. The constituents of the mineral become sulphuric acid and ferrous and ferric oxides, which, by their union, form the salt. Ferrous sulphate is also obtained in many chemical processes as a collateral product, as in the manufacture of alum, in the precipitation of copper from solutions of copper sulphate by scraps of iron, etc.

Commercial ferrous sulphate is far from being pure. Besides containing some ferric sulphate, it is generally contaminated with metallic and earthy salts: such as those of copper, zinc, alumina, and magnesia. Two principal kinds occur in the market, one in large grass-green crystals, the surface of which is studded with ochreous spots;

white by potassium ferrocyanide; but that of ordinary purity gives a greenish precipitate, more or less deep, with this test, owing to the presence of some ferric oxide. Copper may be detected by immersing in the solution a bright piece of iron, on which a cupreous film will be deposited. Both copper and zinc may be discovered by oxidizing the iron by boiling the solution of the salt with nitric acid and then precipitating the iron by an excess of ammonia. If the filtered solution be blue, copper is present; and if it contain zinc, this will be separated in flakes of white oxide on expelling the excess of ammonia by ebullition.

It is often desirable to protect ferrous sulphate against the oxidation to which it is liable on exposure. Sugar acts as a preservative in the case of this salt, as in that of ferrous iodide. It may be added to the solution, or incorporated with the sulphate in substance. M. E. Latour has given a formula for crystallizing the salt with sugar. Mr. Geo. Welborn has found a small lump of camphor, wrapped in tissue-paper and placed in the bottle with the sulphate, to prevent its oxidation. (*P. J. Tr.*, May, 1868, p. 537.) M. Pavesi, of Mortara, effects the same object by incorporating it with an equal weight of gum arabic, by evaporating a joint solution of the two substances with a gentle heat. (*Journ. de Pharm.*, 4e sér., iii. 49.)

Medical Properties and Uses. Ferrous sulphate is a very astringent chalybeate. In overdoses it produces nausea, vomiting, griping, and purging, and other evidences of gastro-enteric irritation or inflammation. Its astringency fits it especially for use when anæmia is conjoined with marked relaxation or a tendency to immoderate discharges, such as *passive hemorrhages*, *colliquative sweats*, *leucorrhœa*, *gleet*, etc. Externally, the solution is used in chronic *ophthalmia*, *leucorrhœa*, and *gleet*, made of various strengths, from one or two to eight or ten grains of the salt to the fluidounce of water. M. Velpeau has found it an excellent remedy in *erysipelas*, applied topically in the form of solution or ointment. The solution was made of three and a half drachms of the salt to a pint of water, and applied by compresses kept constantly wet. In a few cases convenience required the application of the ointment, made of eight parts of the salt to thirty of lard. An ointment made of one or two parts of the sulphate to sixty of lard was found by M. Devergie to be particularly efficacious in certain skin diseases, especially in *eczema*. In scaly affections it had no effect. The dose is from one to two grains (0·065–0·13 Gm.), in the form of pill, which should be made from the dry sulphate. (See *Ferri Sulphas Exsiccatus.*)

Ferrous sulphate, usually in the form of the impure salt or commercial copperas, is a powerful disinfectant, although, according to experiments, its germicidal power is very feeble. When thrown into a mass of decomposing organic matter, a portion of it is at once precipitated as a sulphide or as an oxide by the hydrogen sulphide and ammonia present. It is asserted that ferric sulphate unites with organic substances to form definite stable compounds, and that animal substances kept in a 3-per-cent. solution of neutral ferric sulphate for a length of time and afterwards removed from it mummify without decomposition. (*New Remedies*, Dec. 1883, 685.)

FERRI SULPHAS EXSICCATUS. U. S., Br. Dried Ferrous Sulphate.

(FĔR'RĪ SŬL'PHĂS ĔX-SIC-CĀ'TŬS.)

Approximately $2FeSO_4.3H_2O$; 357·28. $FeSO_4.H_2O$; 169·9.

Ferri Sulphas Exsiccata, *Br.* 1885; Dried Sulphate of Iron; Exsiccated Ferrous Sulphate; Ferrum Sulfuricum Siccum, *P. G.*; Sulfate de Fer desséché, *Fr.*; Entwässertes Schwefelsaures Eisenoxydul, *G.*

"Ferrous Sulphate, in coarse powder, *one hundred grammes* [or 3 ounces av., 231 grains]. Allow the salt to effloresce at a temperature of about 40° C. (104° F.), and then heat it in a porcelain dish, on a water-bath, constantly stirring, until the product weighs from *sixty-four to sixty-five grammes* [or 2 ounces av., 113 grains, to 2 ounces av., 128 grains]. Lastly, reduce the residue to a fine powder, and transfer it at once to perfectly dry, well-stoppered bottles." *U. S.*

"Expose Ferrous Sulphate, $FeSO_4,7H_2O$, in a porcelain or iron dish to a temperature of 212° F. (100° C.), stirring occasionally until aqueous vapor ceases to be given off; reduce the residue, which should weigh about 60 per cent. of the original salt, to a fine powder." *Br.*

Properties. "A grayish-white powder, slowly but completely soluble in water, and conforming approximately to the reactions and tests given under *Ferri Sulphas.*" *U. S.* 100 parts of crystallized ferrous sulphate yield about 65 per cent. of the dried salt. "A nearly white powder, slowly but entirely soluble in *water*. Each gramme dissolved in *water* acidulated with *sulphuric acid* should not cease to yield a blue precipitate with *solution of potassium*

the other of a bluish-green color, and ordinarily mixed with the powder of the effloresced salt. The commercial sulphate should never be dispensed by the pharmacist until it has undergone purification by recrystallization from a slightly acid solution.

ferricyanide until at least 54·6 cubic centimetres of the *volumetric solution of potassium bichromate* have been added, corresponding to at least 92½ per cent. of Exsiccated Ferrous Sulphate, $FeSO_4,H_2O$." *Br.*

In this process six mols. out of seven of the water of crystallization of the salt are driven off. The heat should not exceed 149° C. (300° F.); otherwise the salt itself would suffer decomposition. If the heat has been excessive, the color of the salt will be brownish instead of grayish white. Dried ferrous sulphate is used for making pills, the crystallized sulphate not being adapted to that purpose. In prescribing the dried sulphate it is necessary to recollect that about three grains of it are equivalent to five grains of the crystallized salt.

FERRI SULPHAS GRANULATUS. U. S. Granulated Ferrous Sulphate.

[Ferri Sulphas Præcipitatus, Pharm. 1880.]

$FeSO_4.7H_2O$; 277·42. (FĔR′RĪ SŬL′PHĂS GRĂN-Ū-LĀ′TŬS.) $FeSO_4.7H_2O$; 277·9.

Granulated Sulphate of Iron; Precipitated Ferrous Sulphate, Precipitated Sulphate of Iron.

"Ferrous Sulphate, *one hundred grammes* [or 3 ounces av., 231 grains]; Distilled Water, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Diluted Sulphuric Acid, *five cubic centimeters* [or 81 minims]; Alcohol, *twenty-five cubic centimeters* [or 406 minims]. Dissolve the Ferrous Sulphate in the Distilled Water previously heated to boiling, add the Diluted Sulphuric Acid, and filter the solution while hot. Evaporate the solution immediately in a tared porcelain capsule, on a sand-bath, until it weighs *one hundred and fifty grammes* [or 5 ounces av., 127 grains], and then cool it quickly, under constant stirring. Transfer the product to a glass funnel stopped with a plug of absorbent cotton, and, when it has thoroughly drained, pour upon it the Alcohol. When this also has drained, spread the crystalline powder on bibulous paper, dry it quickly in the sunlight, or in a dry room, at the ordinary temperature, and transfer it at once to perfectly dry, well-stoppered bottles." *U. S.*

The process of the U. S. P. (1890) differs radically in manipulation from that of 1880; instead of pouring the filtered solution of ferrous sulphate into alcohol and collecting the precipitate which falls, the solution is granulated by heat with constant stirring (not quite to dryness), and this salt is then washed with alcohol, which displaces impurities and facilitates the rapid drying of the granular powder.

The product is practically identical with the granulated sulphate of iron of the British Pharmacopœia (1885). The British Pharmacopœia (1898) omitted the granulated salt entirely. The process of the U. S. Pharmacopœia of 1880 had the advantage of being more manageable and convenient, ferrous sulphate being used directly instead of being made by the action of sulphuric acid on the metal. The directions given in the first part of the British process are precisely the same as those laid down by the British Council for making ferrous sulphate; but the hot solution of the iron in the sulphuric acid, instead of being allowed to filter into an empty vessel, is made to drop into a portion of rectified spirit, the mixture being stirred while it cools. The acid directed is in excess; and the filtrate is consequently an acid solution of ferrous sulphate mixed with spirit. The stirring as the mixture cools, finely granulates the salt, which separates perfectly pure, the spirit holding in solution any ferric sulphate which may have been formed, and the excess of acid dissolving any free sesquioxide. This process, in its main features, is that of M. Berthemot. (See 8th ed. U. S. D.)

Properties. "Granulated Ferrous Sulphate is a very pale bluish-green, crystalline powder, which should conform in every respect to the reactions and tests given under *Ferri Sulphas*." *U. S.* Barckhauser, Salzer, and others have stated that ferrous sulphate precipitated by alcohol did not always contain seven molecules of water, and it could not be relied upon for making volumetric solutions because of this lack of uniformity in composition. Caro (*Annalen*, clxv. 29) and Schlickum (*Pharm. Zeitung*, No. 49), on the other hand, maintain that precipitated ferrous sulphate is constant in composition, and Schlickum proved that if the precipitation took place in the cold it always contained seven molecules of water, but *boiling* with strong alcohol diminished the proportion of water of crystallization. This salt is less liable to oxidation on exposure than is the sulphate in its ordinary form, and experience has shown that it is admirably adapted for dispensing.

FERRI VALERIANAS. U. S. Ferric Valerianate.

(FĔR′RĪ VĂ-LĒ-RĬ-Ā′NĂS.) $Fe_2(C_5H_9O_2)_6$; 717·8.

"Ferric Valerianate should be kept in small, well-stoppered bottles, in a cool and dark place." *U. S.*

This preparation, which was official in the old Dublin Pharmacopœia, has been introduced into the United States Pharmacopœia. It is rarely used, because of its insolubility. It may be made by precipitating a diluted solution of ferric sulphate with a solution of sodium valerianate, and collecting and washing the precipitate.

Properties. It is officially described as "a dark brick-red, amorphous powder of somewhat varying chemical composition, having the odor of valerianic acid, and a mildly styptic taste; permanent in dry air. Insoluble in cold water, but readily soluble in alcohol. Boiling water decomposes it, setting free the valerianic acid, and leaving ferric hydrate. When slowly heated, the salt parts with its acid, without fusing, but, when rapidly heated, it fuses and gives off inflammable vapors having the odor of butyric acid, and, on complete ignition, leaves a residue of ferric oxide. The stronger acids decompose the salt with the liberation of valerianic acid. If 0·56 (0·5588) Gm. of the salt be dissolved in a glass-stoppered bottle (having a capacity of about 100 C.c.) in 2 C.c. of hydrochloric acid and 15 C.c. of water, and after the addition of 1 Gm. of potassium iodide the mixture be kept for half an hour at a temperature of 40° C. (104° F.), then cooled and mixed with a few drops of starch test-solution, it should require not less than 15 nor more than 20 C.c. of decinormal sodium hyposulphite volumetric solution to discharge the blue or greenish color of the liquid (each C.c. of the volumetric solution indicating 1 per cent. of metallic iron)." *U. S.*

Medical Properties and Uses. Ferric valerianate is a chalybeate tonic, which has been especially used by some practitioners in anæmia associated with nervous exhaustion and hysteroidal states. It has also been alleged to have almost specific properties in *diabetes insipidus*. Dose, from two to five grains (0·13–0·33 Gm.)

FERRUM. U. S., Br. Iron.

Fe; 55·88. (FĔR'RŬM.) **Fe; 55·9.**

"Metallic Iron, in the form of fine, bright, and non-elastic wire." *U. S.* "Annealed iron wire, having a diameter of about 0·005 inch (0.1 millimetre) (about No. 35 wire gauge), or wrought-iron nails, free from oxide." *Br.*

Fer, *Fr.;* **Eisen,** *G.;* **Ferro,** *It.;* **Hierro,** *Sp.;* **Mars,** *Fr.*

In the U. S. Pharmacopœia, this metal is employed in different preparations, in the form of wire; it was official in 1850 as *Ferri Ramenta*, Iron Filings.

Iron is the most abundant and useful of the metals, and so interwoven with the wants of mankind that the extent of its consumption by a nation may be taken as an index of progress in civilization. It is universally diffused in nature, not only in the mineral but also in the vegetable and animal kingdoms. There are very few minerals in which traces of it are not to be found, and it is an essential constituent in many parts of animals, but particularly in the blood. It is one of the few metals which are not deleterious to the animal economy. Iron occurs 1—native (almost exclusively, however, of meteoric origin); 2, sulphuretted, in the minerals pyrites (simple ferric sulphide), pyrrotine or magnetic pyrites, and arsenopyrite or mispickel (a sulph-arsenide of iron); 3, oxidized, embracing the magnetic, specular, red, brown, and argillaceous iron oxides, also chromite (mixed iron, chromium, and magnesium oxides) and franklinite (mixed iron, manganese, and zinc oxides); 4, in saline combination, forming ferrous carbonate, sulphate, phosphate, and arsenate. Those minerals of iron which admit of being worked to advantage are called iron ores. These include the different native oxides, and the carbonate (spathic iron). The best iron is obtained from varieties of the native oxide, usually called magnetic iron ore and specular iron ore. These occur abundantly in Sweden, and furnish the superior iron of that country. The upper peninsula of Michigan now yields similar ores. As a rule, those ores yield the best iron which occur in primitive formations.

Extraction. The mode of extracting iron from its ores varies somewhat with the nature of the ore; but the general principles of the operation are the same for all. The ore, previously broken into small pieces and roasted, is exposed to the action of an intense heat, urged by an air-blast, in contact with carbonaceous matter, such as charcoal, coke, or anthracite, and in connection with some flux capable of fusing with the impurities of the ore. The flux varies with the nature of the ore, and is generally limestone. Fluorspar is occasionally used, but is not often found in sufficiently large deposits to be available. The flux, whatever it may be, enters into fusion with the impurities, and forms what is called the slag, which is a fusible lime silicate chiefly; while the carbon monoxide formed from the carbonaceous matter, acting on the ferric oxide, reduces it to the metallic state. The reduced metal, from its density, occupies

the lower part of the furnace, and is protected from the action of the air by the melted slag which floats on its surface. When the reduction is completed, the slag is allowed to run out by a hole in the side of the furnace, and the melted metal by an aperture at the bottom, the latter being received into a series of sand-moulds, where it solidifies in masses, known in commerce by the name of *pig-* or *cast-iron*. In this state the metal is brittle and far from being pure, as it contains from 3 to 6 per cent. of carbon, with silicon, phosphorus, sulphur, and manganese. It is purified, and brought to the state of *malleable iron*, by being fused and subjected, while stirred, to the action of a current of air on its surface. By these means the carbon is nearly burnt out, and the other impurities are oxidized and made to rise to the surface as a slag. Instead of this process, called "refining," usage in this country and in England substitutes what is called "pig-boiling,"—that is, the pig-iron is at once submitted to the operation of puddling without previous refining. The "puddling" process consists in heating the charge of pig-iron on the hearth of a reverberatory furnace in contact with ferric oxide and in a reducing flame. The silicon is first burnt out, and then the carbon gradually disappears; the phosphorus goes into the "tap cinder" as phosphide and phosphate; the sulphur in part disappears as sulphur dioxide and in part remains in the cinder as ferrous sulphide. As the metal approaches to purity, it becomes tough and less liquid, and its particles agglutinate so as to form semi-fused lumps, though the temperature of the furnace continues the same. These lumps are then taken out of the furnace, and their particles, by means of ponderous hammers moved by steam or water power, or by great pressure, are forced together so as to form one tenacious mass. The metal is finally rolled out into bars of a convenient size, when it constitutes the malleable iron of commerce.

The third form of commercial iron, known as "steel," is made either by the *cementation* process, the *Bessemer* process, or the *open-hearth* process. In the first case, wrought-iron is packed with charcoal and heated until combination takes place, and the resulting steel is cast into ingots. In the second case, cast-iron is melted in large vessels called converters, when a blast of air is blown through the mass, burning out the requisite amount of carbon, and then, after addition of a small amount of *spiegeleisen*, or manganiferous cast-iron, the finished product is run into moulds; while in the third or open-hearth process, a mixture of pig-iron and ore is heated with a reverberatory flame, as in the puddling process, or bars and blooms of wrought-iron are heated with the pig-iron, and steel is made by the combination of the two. Steel contains from $\frac{1}{2}$ to 1 per cent. of carbon.

The production of pig-iron in the United States in 1896 was 8,623,127 tons, and in 1897, 9,652,680 tons, while in Great Britain the output for the same years was 8,659,681 tons and 8,850,000 tons respectively. The steel production of the United States was, for 1886, 5,582,606 tons, and for 1897, 7,174,508 tons.

Iron mines occur in most countries, but more particularly in northern ones. In Spain the principal mines furnish spathic iron and the red oxide. The chief iron ores of France are the spathic iron, and the specular, brown, and argillaceous oxides; of Germany, the spathic iron and brown oxide. The island of Elba is celebrated for its rich and abundant specular iron ore. In the United States iron is abundant. The principal ores that are worked are the magnetic, red, and brown oxides. The magnetic oxide is found in large beds in Essex Co., N.Y., on the borders of Lake Champlain, and in the Lake Superior district; the red oxide in New York, New Jersey, Pennsylvania, Alabama, and especially in a very pure state in Missouri, at Iron Mountain and Pilot Knob; the brown oxide in Eastern Pennsylvania.

Properties. Iron is a hard, malleable, ductile, and tenacious metal, of a grayish-white color and fibrous texture, a slightly styptic taste, and a sensible odor when rubbed. In tenacity it yields only to nickel and cobalt. (*Deville.*) Its sp. gr. is about 7·7 (7·8, *U. S.*), and its fusing point very high. It possesses the magnetic and welding properties. It is combustible, and, when heated to whiteness, burns in atmospheric air, and with brilliant scintillations in oxygen gas. At a red heat, its surface is converted into black oxide, and at common temperatures, by the combined agency of air and moisture, it becomes covered with a yellowish-brown matter, called *rust*, which is the hydrated sesquioxide. It combines with all the non-metallic elements, except hydrogen and nitrogen, and with most of the metals. It forms three compounds with oxygen, a ferrous oxide and a ferric oxide, which by their union form the native magnetic oxide, hence often termed ferroso-ferric oxide, and a trioxide, which forms an acid called ferric acid. The *monoxide*, or ferrous oxide, is of a dark blue color, attracted by the magnet, and spontaneously combustible in the air, being converted into sesquioxide or ferric oxide. It is the base of ferrous sulphate, and of the green salts of iron generally. It is

very prone to absorb oxygen; and hence the salts which contain it are soon partially converted, when in solution, into salts of the ferric oxide. Its formula is FeO, consisting of one atom of iron, Fe, and one of oxygen, O. The *sesquioxide*, or ferric oxide, is readily obtained by dissolving iron in hydrochloric acid, precipitating by ammonia, and igniting the precipitate. It is of a red color, not attracted by the magnet, and forms salts which for the most part have a reddish color. Its formula is Fe_2O_3, consisting of two atoms of iron, Fe, and three atoms of oxygen, O. An allotropic variety of the sesquioxide, soluble in water, and not responding to the ordinary tests of iron, has been discovered by M. Péan de Saint-Gilles. The *native black oxide*, the magnetic oxide of mineralogists, consists of one molecule of FeO and one molecule of Fe_2O_3. Under the name of *Ferri Oxidum Magneticum*, the British Pharmacopœia has a preparation consisting of this oxide with three mols. of water. *Ferric acid*, discovered by Frémy, may be obtained, in union with potassa, by passing chlorine through a very concentrated solution of the alkali, holding the hydrated ferric oxide in suspension, or by fusing iron filings with potassium nitrate. The acid anhydride consists of one atom of iron and three of oxygen. Iron forms a number of important salts.

Iron is readily detected, even in minute quantities, by bringing it to the state of ferric salt in solution, and adding potassium ferrocyanide or tincture of galls; the former of which will strike a deep blue, the latter a black color. Bringing it to the state of a ferric salt is readily effected by boiling the solution containing it with a little nitric acid. The testing of the official scaled salts of iron has attracted the attention of chemists, it being well known that these are not definite chemical compounds. Dr. F. B. Power prefers the *iodometric method* for estimating the quantity of iron in scaled salts. It is based on the liberation of iodine by a solution of ferric chloride, and the subsequent estimation of the liberated iodine by a decinormal solution of sodium thiosulphate. (*Pharm. Rund.*, 1891, 205.)

General Therapeutic Effects of Iron. Since iron constitutes an integrant portion of the red blood-corpuscles, it is a necessity for their production, and the great indication for its use is lack of hæmoglobin in the blood,—*i.e.*, *anæmia*. It is plain that the lack of hæmoglobin may be due to the lessening of the number of the red blood-corpuscles, or it may be the outcome of a lack of the normal amount of hæmoglobin in the individual blood-corpuscles. The distinction between these two varieties of anæmia is important, since clinical experience has shown that in anæmia of the first of these classes—the so-called "*essential anæmias*," in which there is a marked diminution of the number of the red blood-corpuscles—the prognosis is very grave; whilst in *simple anæmias* in which there is simply poverty of hæmoglobin the prognosis is favorable. In essential anæmias iron may be administered, but is of very little value. In the non-essential or simple anæmias the effect of the administration of iron varies with the cause of the anæmia, but is usually more or less favorable. In the so-called *accidental anæmias*, in which the poverty of the blood is due to some temporary, removable, or self-disappearing cause, such as hemorrhage, snake or other poisonings that destroy the red blood-corpuscles, iron is of great service in hastening the recovery after the immediate activity of the cause has ceased. In *secondary anæmias*, such as those which follow impaired digestion, diarrhœa, abscesses, and various chronic diseases, iron should be exhibited, provided it has no injurious effect upon the disease which is producing the anæmia. In the class of anæmias typified by *chlorosis*, in which the anæmia is part of a subacute disease of obscure nature, iron is often an extraordinarily effective remedy, evidently doing something more than merely supplying material for the making of the red blood-corpuscles. By stimulating the organs which produce the red blood-corpuscles, or in some other less direct manner, it evidently increases the manufacture of hæmoglobin in the system.

The old belief that iron is a tonic, independent of its influence upon anæmia, is a mistake, there being no sufficient reason for supposing that iron has other therapeutic properties than those of astringency and of chalybeate action, except some special preparations, such as the iodide and the chloride, which are peculiar in their influence by virtue of some substance in them other than the iron.

The question of the selection of a preparation of iron for an individual case is often one of great importance. If it be simply desired to combat anæmia, a preparation should be selected which is free as may be from astringency or peculiar property and is suitable to the individual taste of the patient. Most of the liquid preparations of iron are more or less injurious to the teeth, so that commonly it is preferable to give a solid salt in pill or capsule rather than one of the liquid forms, unless the latter be especially indicated.

The question of the capability of iron preparations of being absorbed is one which has called

for an amount of chemical investigation which is so great that even to epitomize it would carry us beyond the proper bounds of this article, and we are therefore forced to refer our readers to the last edition of H. C. Wood's *Therapeutics*. It is sufficient to note that many chemists have asserted that most, if not all, of the official preparations of iron are practically not absorbed,—a conclusion which is so at variance with an overwhelming amount of clinical evidence that it could not, under any circumstances, be accepted by clinicians; moreover, it is at present opposed by recent chemical researches, which show many fallacies underlying the older work, and strongly indicate the correctness of the position which clinicians have steadily held to,—namely, that the human body is capable of absorbing iron from almost all, if not all, of the pharmacopœial preparations. Spurred on by the theory that the inorganic salts of iron are not absorbed, pharmaceutical chemists have devised various organic compounds which will be considered in detail in the second part of this book. There is, however, no sufficient reason for believing that these complicated and costly preparations of iron are in any way superior to the older official forms. Even in the official list the hand of the pharmaceutical chemist shows very plainly in useless multiplication. It would probably be much better if the Pharmacopœia recognized only a fraction of the present official preparations. All that can be accomplished with any preparation in simple anæmia can be done with reduced iron or pill of the carbonate for exhibition in solid form and the ammonio-citrate for liquids. No compounds in which iron is combined with an alkaloid should be recognized by the Pharmacopœia or used by the practitioner. Of course such combinations are to a greater or less extent effective, but the proportionate amount of the alkaloid and the iron required in individual cases varies indefinitely, and the habitual use of a fixed proportion, such as is demanded by the pharmacopœial combinations, strongly inclines the practitioner of medicine to careless and routine practice. The official alkaloidal-ferruginous preparations have no advantage whatever over extemporaneous prescriptions combining iron and the alkaloid.

Certain salts of iron are extremely astringent and more or less irritant. The most important of these are the sulphates and the chlorides. These salts should never be employed as chalybeates, except in those cases in which, for some reason, astringency is desired. Although the mildest of the pure chalybeate preparations of iron are somewhat astringent, and have a tendency to produce constipation, they are also somewhat irritant to the mucous membrane of the gastro-intestinal tract. Such salts as the sulphate or the chloride are very astringent and very irritating. Any functional disarrangement of the digestive organs is a contraindication of greater or less force to the use of iron, and when the loss of functional power depends upon gastric or intestinal catarrh, or upon other organic diseases of the gastro-intestinal mucous membrane, iron is strongly contraindicated. We have often seen great injury done to patients suffering from gastro-intestinal catarrh by the iron given with the hope of relieving the anæmia, which has been secondary to the interference with digestion by the disease. A second contraindication to the use of iron is a rheumatic diathesis, though in rare cases of *chronic rheumatism* in which there is pronounced anæmia iron may do good. In most cases some laxative should be combined with iron to overcome its constipating influence.

The hypodermic use of iron has been tried to some extent. It has been shown by the chemists working under Prof. Kobert, of Dorpat, that when a solution of iron and sodium citrate is injected subcutaneously in man, 40 per cent. of the iron escapes in the urine unaltered, the elimination of the iron usually being accompanied by pronounced renal irritation. The hypodermic use of some of the organic compounds of iron has been strongly recommended by investigators. The latest researches seem, however, to show that the iron citrate is as good a preparation for the hypodermic administration of iron as any other, the iron appearing in the urine half an hour after its injection and being present for twenty-four hours. According to Gloevecke, 1 C.c. of a 10 per cent. solution, thrown into the muscles of the back, causes an enduring sharp pain, but Lepine asserts that 2.5 C.c. of a 4 per cent. solution produces little or no disturbance. It is stated that after the hypodermic injection of large doses the irritation of the alimentary canal is more severe than when the drug is given by the mouth,—a statement which finds confirmation in the experiments of Gottlieb, who found that when he injected iron subcutaneously into the dog he was able to obtain nearly 97 per cent. of it from the fæces. The effort at intestinal elimination is evidently accompanied by irritation if the amount of iron to be eliminated is large. Unsoundness of the kidney is an absolute contraindication to the hypodermic use of iron; hæmaturia and urinary suppression have been pro-

duced by the remedy under such circumstances. In ordinary cases of anæmia iron should not be used hypodermically, but when, under the influence of certain poisons, there is very rapid destruction of the hæmoglobin the method may be employed, and trials of it in the essential anæmias are justifiable.

IRON FILINGS. *Ferri Ramenta.* U. S. 1850. *Limatura Ferri.*

Limailles de Fer, *Fr.;* Eisenfeilicht, *G.;* Limatura di Ferro, *It.;* Limatura de Hierro, *Sp.*

Iron, when employed in pharmaceutical operations, should be of the purest kind; and hence the Pharmacopœias generally direct it, when wanted in small masses, to be in the form of *iron wire*, which is necessarily made from the purest, because the softest and most ductile, iron, and is readily cut into pieces. The wire is very flexible and without elasticity.

Iron filings are usually obtained from the workshops of the blacksmith; but, as furnished from this source, they are generally very impure, and unfit for medicinal use. M. Gobley, upon examining thirty-six samples of iron filings, found but three exempt from copper; the rest, besides wood, sand, and ferric oxide, contained as high as 2 per cent. of this metal. Iron filings cannot be completely purified by the magnet, as they often have adhering to them bits of foreign matter which are carried up with them. The only way to obtain them pure is to file a piece of pure iron with a clean file. The French Codex directs iron in an *impalpable powder* prepared by porphyrizing bright and clean iron filings without water. A dull black powder is formed, which must be carefully preserved from moisture. An impalpable powder of the metal, *Ferrum Reductum*, is official.

FERRUM REDUCTUM. U. S. (Br.) Reduced Iron.

(FĔR'RŬM RĒ-DŬC'TŬM.)

"A fine powder, containing at least 75 per cent. of metallic iron, with a variable amount of iron oxide; prepared by reducing ferric hydroxide, heated to dull redness, by a stream of dry hydrogen." *Br.*

Ferrum Redactum, *Br., P. G., U. S.* 1870; Ferri Pulvis, *U. S.* 1850; Powder of Iron; Ferrum Hydrogenio Reductum, Ferrum Ope Hydrogenii Paratum; Iron reduced by Hydrogen, Iron by Hydrogen; Fer réduit par l'Hydrogène, *Fr.;* Reducirtes Eisen, *G.*

A process for this form of iron is no longer given in the United States Pharmacopœia.*

This preparation was introduced into the United States and Dublin Pharmacopœias of 1850, and is retained in the present edition of our own, although the process for it has been abandoned. It consists of metallic iron in fine powder, obtained by reducing the ferric oxide by hydrogen at a dull red heat. The subcarbonate of the U. S. Pharm. 1870, which is essentially the ferric oxide, is deprived of water by calcination, and then subjected to the reducing influence of a stream of hydrogen, purified from hydrogen sulphide and other acid by passing successively through a solution of lead subacetate and milk of lime. The hydrogen unites with the oxygen of the ferric oxide to form water, and leaves the iron in the metallic state. The subcarbonate should be perfectly free from sodium sulphate, which it is apt to contain when imperfectly washed. If this salt be present, it will be reduced by the hydrogen to the state of sodium sulphide, which will contaminate and spoil the metallic iron formed, and cause the preparation, when taken, to give rise to unpleasant eructations. The heat should be carefully regulated; for if it fall below dull redness, part of the oxide will escape reduction; and if it exceed that point considerably, the particles of reduced iron will agglutinate, and the prepara-

* *Ferrum Redactum.* "Take of Subcarbonate of Iron *thirty troyounces.* Wash the Subcarbonate thoroughly with water until no traces of sulphate of sodium are indicated by the appropriate tests, and calcine it in a shallow vessel until free from moisture. Then spread it upon a tray, made by bending an oblong piece of sheet-iron in the form of an incomplete cylinder, and introduce this into a wrought-iron reduction-tube, of about four inches in diameter. Place the reduction-tube in a charcoal furnace; and, by means of a self-regulating generator of hydrogen, pass through it a stream of that gas, previously purified by bubbling successively through solution of subacetate of lead, diluted with three times its volume of water, and through milk of lime, severally contained in four-pint bottles, about one-third filled. Connect with the further extremity of the reduction-tube a lead tube bent so as to dip into water. Make all the junctions air-tight by appropriate lutes; and, when the hydrogen has passed long enough to fill the whole of the apparatus to the exclusion of atmospheric air, light the fire, and bring that part of the reduction-tube, occupied by the Subcarbonate, to a dull-red heat, which must be kept up so long as the bubbles of hydrogen, breaking from the water covering the orifice of the lead tube, are accompanied by visible aqueous vapor. When the reduction is completed, remove the fire, and allow the whole to cool to the ordinary temperature, keeping up, during the refrigeration, a moderate current of hydrogen through the apparatus. Withdraw the product from the reduction-tube, and, should any portion of it be black instead of iron-gray, separate such portion for use in a subsequent operation. Lastly, having powdered the Reduced Iron, keep it in a well-stopped bottle. When thirty troyounces of Subcarbonate of Iron are operated on, the process occupies from five to eight hours." *U. S.* 1870.

tion will be heavy and not readily pulverizable. The 1885 British process is not so well fitted for practical purposes as is that of the U. S. Pharm. 1870. In the 1885 revision of the British Pharmacopœia, instead of directing a certain quantity of hydrated ferric oxide, a process is given in the formula for making the ferric oxyhydrate by precipitating a solution of ferric chloride. The direction to dry the hydrogen is unnecessary. On the subject of powder of iron, manufacturing chemists will find it useful to consult the paper of MM. Soubeiran and Dublanc, in which full directions are given for purifying the hydrogen, constructing the furnace, regulating the heat, and avoiding explosions. (*A. J. P.*, xviii. 303.) For improvements by Prof. Procter, see *A. J. P.*, xix. 11. The necessity for purification of the hydrogen by passing it successively through concentrated potassium permanganate solution, lead acetate solution, and sulphuric acid has been proved by T. Appel. (*Oest. Zeit. f. Pharm.*, 1892, 395.)

Since the tenth edition of this work was published, several processes have been proposed for obtaining powder of iron. Mr. Arthur Morgan, of Dublin, recommended the use of dried potassium ferrocyanide, thoroughly mixed with anhydrous ferric oxide, and calcined with pure potassium carbonate at a low red heat. The product contains all the iron in a reduced state, mixed with soluble matters, which are carefully washed away. (See *A. J. P.*, 1854, p. 450). A similar process to the above has been proposed by a German chemist, named Zängerle, iron oxalate being substituted for the ferric oxide. (See *P. J. Tr.*, 1857, p. 565.) Prof. Wöhler recommended the use of the same oxalate, not in connection with potassium ferrocyanide, but as a suitable compound of iron for reduction by hydrogen. W. Müller found that ferric oxide obtained by heating the metal in the air is reduced when moist at 293° C. (559·4° F.); when quite dry, at 305° to 339° C. (581° to 642·2° F.); the oxalate moist, at 278° C. (532.4° F.). Another eligible compound for reduction is the crystalline powder of ferric oxide, prepared by fusing, in a clay crucible, pure dried ferrous sulphate with three times its weight of sodium chloride, and then washing the melted mass when cold, until everything soluble is removed. (*Wöhler.*) M. Crolas prepares a pure ferric oxide by adding barium chloride to the solution of ferric chloride to precipitate the contaminating sulphate, getting rid of the barium chloride by crystallization and precipitating by solution of ammonia. The ammonium chloride is driven off by heat. (*Journ. de Pharm.*, 4e sér., xx. 30.) The process of M. Eugène Fegueux consists in reducing the ferric oxide by carbonic oxide, formed by passing a stream of carbonic acid over red-hot charcoal in the reduction-tube, before it reaches the ferric oxide. The carbonic acid, thus reduced to carbonic oxide, is formed again by the deoxidizing of the ferruginous oxide.

Under the name of "*alcoholized iron*," a powder of iron has been introduced into this country, said to be prepared, in the eastern parts of Germany, by attrition of iron filings with honey, by some cheap method, as by attachment to a saw-mill or steam machinery. It has the appearance of powdered plumbago, but under the magnifying glass is seen to contain particles with the metallic lustre and rounded as if by friction. It is soluble in diluted sulphuric acid, with the escape of hydrogen free or nearly so from sulphur; but a small quantity of a black powder remains undissolved. (*A. J. P.*, 1867, p. 11.) The relation of the epithet "alcoholized" to this powder is not very obvious, as this name was given originally to iron obtained by passing alcohol vapor over ferric oxide. It is not much inferior to reduced iron, and is better than some preparations sold by that name.

Properties. Powder of iron, called by the French *fer réduit*, is a light, tasteless powder, soft to the touch, of an iron-gray color, and without metallic lustre. If black, the preparation is to be rejected as not being fully deoxidized. When thrown into a dilute acid, it causes a lively effervescence of hydrogen without odor. A small portion of it, struck on an anvil with a smooth hammer, forms a scale having a brilliant metallic lustre. It takes fire upon the application of a burning body. On account of its great liability to oxidation, it should be kept in a dry bottle, well stopped. A black powder, having a composition corresponding with that of the magnetic oxide of iron, has been sold in London and Edinburgh under the name of Quevenne's iron. The spurious powder may be known by its having a black instead of an iron-gray color, and by its effervescing but slightly with acids. In the process for making reduced iron, part of the sesquioxide almost always escapes full deoxidation, and comes out of the tube a black color. This part should be rejected, instead of being sold as reduced iron, as appears to have been done by some manufacturing chemists. If the preparation has been very badly made, its solution in dilute sulphuric acid will produce an intensely red color with potassium sulphocyanide. It is officially described as "a very fine, grayish-black, lustreless powder, without

odor or taste; permanent in dry air. Insoluble in water or alcohol. When treated with diluted sulphuric acid, it causes the evolution of nearly odorless hydrogen gas, which should not affect paper moistened with lead acetate test-solution (absence of *sulphide*), and, on applying a gentle heat, the Iron should dissolve in the acid without leaving more than 1 per cent. of residue. When ignited, in contact with air, it glows and is converted into black ferroso-ferric oxide. If 1 Gm. of Reduced Iron be shaken with 5 C.c. of water, the liquid should not change the color of litmus paper. If 0·5 Gm. of Reduced Iron be added to 5 C.c. of arsenic-free hydrochloric acid, and the mixture be poured upon a filter while still effervescing, 1 C.c. of the clear filtrate should, after the addition of 2 C.c. of stannous chloride test-solution (see List of Reagents, Bettendorff's Test for Arsenic), together with a small piece of pure tin-foil, and gentle heating, show no brown coloration within half an hour (limit of *arsenic*).

"*Estimation of the Metallic Iron.* Introduce 0·56 (0·559) Gm. of Reduced Iron into a glass-stoppered bottle, add 50 C.c. of mercuric chloride test-solution, and heat the bottle, well stoppered, during one hour on a water-bath, frequently agitating. Then allow it to cool, dilute the contents with water to the volume of 100 C.c., and filter. To 10 C.c. of the filtrate, contained in a glass-stoppered bottle (having a capacity of about 100 C.c.), add 10 C.c. of diluted sulphuric acid, and subsequently potassium permanganate decinormal volumetric solution, until a permanent red color is produced. The number of C.c. of the volumetric solution required, when multiplied by *ten*, will indicate the percentage of metallic iron. To confirm the assay, decolorize the liquid by a few drops of alcohol, then add 1 Gm. of potassium iodide, and digest for half an hour at a temperature of 40° C. (104° F.). The cooled solution, mixed with a few drops of starch test-solution, should require not less than 8 C.c. of sodium hyposulphite decinormal volumetric solution to discharge the blue or greenish color (each C.c. of the volumetric solution indicating 10 per cent. of metallic iron)." *U. S.* "A fine grayish-black powder, strongly attracted by the magnet, and producing metallic streaks when rubbed with firm pressure in a mortar. It dissolves in *hydrochloric acid* with the evolution of hydrogen, and without any smell of hydrogen sulphide, and the solution gives a light blue precipitate with *solution of potassium ferrocyanide*. If 0·25 gramme be added to a hot solution of 1 gramme of *copper sulphate* in 15 cubic centimetres of *water*, in a flask that can immediately be well corked, and the whole be shaken occasionally during ten minutes, the liquid, after being rapidly filtered with the minimum of exposure to air, and acidulated with sulphuric acid, should not cease to yield a blue precipitate with *solution of potassium ferricyanide* until at least 33·7 cubic centimetres of the *volumetric solution of potassium bichromate* have been added." *Br.*

J. Creuse communicated a valuable paper to the Amer. Pharm. Association in 1874, in which he showed the deficiencies of many brands of commercial iron by hydrogen, and recommended a test based on an estimation of the amount of hydrogen liberated from a definite weight of the reduced iron. An examination of the commercial *Ferrum Reductum* has also been made and the results given in *Proc. A. P. A.*, 1894, 172, 292. O. Wilner (*A. J. P.*, 1881, 15) states that—1. The amount of metallic iron in reduced iron can be accurately determined by treatment with mercuric chloride and titration with potassium permanganate. 2. If metallic iron be treated by the aid of a gentle heat with an excess of a concentrated solution of mercuric chloride, mercurous chloride and metallic mercury will be separated, and the metallic iron pass as ferrous chloride into solution; the ferrous and ferric oxides which may be present remain undissolved, and therefore do not prevent the estimation of the amount of metallic iron in the reduced iron. 3. The amount of ferrous oxide in the preparation may be estimated by treating the same portion with hydrochloric acid, digesting the mixture in a closed vessel until the finely divided ferrous oxide becomes dissolved, and titrating with potassium permanganate. 4. The ferric chloride which is thus formed at the same time has no appreciable action upon the precipitated metallic mercury and mercurous chloride.

Medical Properties. Powder of iron, reduced from the oxide by hydrogen, was first prepared for medicinal purposes by Quevenne and Miquelard of Paris. It is one of the best of chalybeate tonics, nearly free from astringency, and, according to Quevenne and M. Costes of Bordeaux, yields the largest proportion of iron to the gastric juice. The chief objection to it is the difficulty of obtaining it well prepared. Much of the powder of iron found in commerce is not to be depended on, in consequence of imperfect reduction. Observations to determine its therapeutic value, compared with that of the other ferruginous preparations, were made by M. Costes, for nearly four years, at the Saint-André hospital of Bordeaux, with results highly favorable to it. The dose is from three to six grains (0·20–0·40 Gm.) several times a day, given in powder or in pill. It is sometimes prepared with chocolate in the form of lozenges.

FICUS. U. S., Br. Fig.

(FĪ'CŬS.)

"The fleshy receptacle of Ficus Carica, Linné (nat. ord. Urticaceæ), bearing fruit upon its inner surface." *U. S.* "The dried fleshy receptacles of Ficus Carica, Linn." *Br.*

Caricæ, *P. G.;* Ficus Passa, Fici, Fructus Caricæ; Figues, *Fr.;* Feigen, *G.;* Fichi, *It.;* Higos, *Sp.*

Engler and Prantl divide the Urticaceæ into three distinct orders,—viz., Urticaceæ proper, including Urtica; Ulmus, including Ulmus; and the Moraceæ, including Ficus, Humulus, and Cannabis.

The genus Ficus yields a number of economic products. Many species possess a milky juice containing caoutchouc, as *F. elastica* Roxb., of Sumatra, etc. Some of the juices are employed externally as well as internally, as that of *F. indica* L. Some possess anthelmintic properties, as *F. anthelmintica* Mart. Some yield gum lac or shellac as a result of the puncture of an insect, as *F. religiosa* L., *F. laccifera* Roxb.; and some are esteemed for their fruits, as *F. Carica* L., *F. religiosa* L., etc.

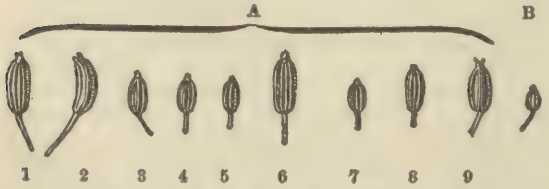
Ficus Carica. Willd. *Sp. Plant.* iv. 1131; Woodv. *Med. Bot.* p. 714, t. 244. The fig-tree, though often not more than twelve feet high, sometimes rises in warm climates twenty-five or even thirty feet. Its trunk, which seldom exceeds seven inches in diameter, is divided into numerous spreading branches, covered with a brown or ash-colored bark. Its large, palmate leaves, usually divided into five obtuse lobes, are deep green and shining above, pale green and downy beneath, and stand alternately on strong, round footstalks. The flowers are situated within a common receptacle, placed upon a short peduncle in the axils of the upper leaves. This receptacle, the walls of which become thick and fleshy, constitutes what is commonly called the fruit; though this term is, strictly speaking, applicable to the small seed-like bodies found in great numbers on the internal surface of the receptacle, to which they are attached by fleshy pedicels. Cultivation has produced in the fig, as in the apple and peach, a great diversity in shape, size, color, and taste. It is usually, however, turbinate, or top-shaped, umbilicate at the large extremity, of the size of a small pear, of a whitish, yellowish, or reddish color, and of a mild, mucilaginous, saccharine taste. The dried figs can be partially restored to their original shape by soaking. The fig-tree is supposed to have come originally from the Levant. It was introduced at a very early period into various parts of the south of Europe, and is now very common throughout the whole basin of the Mediterranean, particularly in Italy and France. Large numbers of Syrian fig-trees were planted in the Pomona Valley, California, in 1890, and California figs may now be found in commerce. To hasten the ripening of the fruit, it is customary to puncture it with a sharp-pointed instrument covered with olive oil. The ancient process of *caprification* is still practised in the Levant. It consists in attaching branches of the wild fig-tree to the cultivated plant. The fruit of the former contains great numbers of the eggs of an insect of the genus Cynips, the larvæ of which, as soon as they are hatched, spread themselves over the cultivated fruit, and, by conveying the pollen of the male organs over which they pass to the female florets, hasten the impregnation of the latter, and cause to quickly come to perfection the fig which might otherwise ripen very slowly, or wither and drop off before maturity. Some authors attribute the effect to the piercing of the fruit by the young insects. According to Landerer, the unripe fig contains an irritant juice, which inflames the skin, and may even disorganize it. (See *A. J. P.*, xxxiii. 215.) The figs, when perfectly ripe, are dried by the heat of the sun, or in ovens. Those imported into this country come chiefly from Smyrna, packed in drums or boxes. They are more or less compressed, and are usually covered in cold weather with a whitish saccharine efflorescence, which melts in the middle of summer and renders them moist. The best are yellowish or brownish, somewhat translucent when held to the light, and filled with a sweet viscid pulp, in which are lodged numerous small yellow seeds. They are much more saccharine than is the fresh fruit. Their chief constituents are grape sugar, and gum or mucilage. An average of several analyses of dried figs as quoted by König (*Nahrungsund Genussmittel*, 3te Aufl., Bd. i. 781) gives—water, 31·20; nitrogenous material, 4·01; sugar, 49·79; ash, 2·86. Reckoned on the weight of absolutely dry material, the nitrogenous matter amounted to 5·75 per cent. and the sugar to 72·26 per cent.

Medical Properties and Uses. Figs are nutritious, laxative, and demulcent. In the fresh state they are considered, in the countries where they grow, a wholesome and agreeable aliment, and have been employed from time immemorial. They are apt, however, when eaten freely, to produce flatulence, pain in the bowels, and diarrhœa. Their chief medical use is as

a laxative article of diet in constipation. They occasionally enter into demulcent decoctions, and, roasted or boiled, and split open, are sometimes applied as a cataplasm to inflamed gums.

FŒNICULUM. U. S. (Br.) Fennel.

(FŒ-NĬC'Ŭ-LŬM—fē-nĭk'yŭ-lŭm.)



"The fruit of Fœniculum capillaceum, Gilibert (nat. ord. Umbelliferæ)." *U. S.* "The dried ripe fruit of Fœniculum capillaceum, Gilib., collected from cultivated plants." *Br.*

Fœniculi Fructus, *Br.;* Fructus Fœniculi, *P. G.;* Fennel Fruit (Seed), Sweet Fennel Fruit; Fenouil, Fruits (Semences) de Fenouil, *Fr.;* Fenchel, Fenchelsamen, *G.;* Finnochio, *It.;* Hinojo, *Sp.*

The plant producing fennel-seed was attached by Linnæus to the genus *Anethum*, but was separated from it by De Candolle, and placed, with three or four others, in a new genus styled *Fœniculum*, which has been generally adopted by botanists. The *Anethum Fœniculum* of Linnæus embraced two varieties, the *common* or *wild fennel*, and the *sweet fennel;* the latter being the plant usually cultivated in the gardens of Europe. These are considered by De Candolle as distinct species, and named respectively *Fœniculum vulgare* and *Fœniculum dulce*, but the correctness of the opinion of the great Swedish botanist is now generally admitted.

Fœniculum capillaceum. Gilib. *Fl. Lithuan.* iv. 1782.—*Fœniculum vulgare.* De Cand. *Prodrom.* iv. 142.—*Anethum Fœniculum.* Linn.—*Fœniculum Fœniculum* (L.). Karst., Britton, and Brown. *Common Fennel* has a biennial or perennial tapering root, and an annual, erect, round, striated, smooth, green, and copiously branching stem, which usually rises three or four feet in height. The leaves, which stand alternately at the joints of the stem, upon membranous striated sheaths, are many times pinnate, with long, linear, pointed, smooth, deep-green leaflets. The flowers are in large, flat, terminal umbels, with from thirteen to twenty rays, and destitute both of general and partial involucres. The corolla consists of five petals, which, as well as the stamens, are golden yellow. The fruit is ovate, rather less than two lines in length by about a line in breadth, and of a dark color, especially in the channels. The plant is a native of Europe, growing wild upon sandy and chalky ground throughout the continent, and is also abundant in Asia, possibly extending as far as China. The variety *F. officinale* of Mérat and De Lens is chiefly characterized by its fruit being twice as long as is that of the ordinary plant, and also a little curved, of a less dark color, with prominent ridges, and a persistent peduncle. It is sweeter and more aromatic than is common fennel-seed. In India fennel is said to be obtained from *F. panmorium* D. C., which is probably, however, only a variety of the official plant. Sicilian fennel is affirmed to be the fruit of *F. piperitum.*

F. dulce. De Cand. *Prodrom.* iv. 142. *Sweet Fennel* bears a general resemblance to *F. vulgare*, but differs in having its stem somewhat compressed at the base, its radical leaves

A, Fennel Fruits: 1, German; 2, French (curved, sweet); 3, Galician; 4, Russian; 5, French (bitter); 6, Indian; 7, Japanese; 8, Persian; 9, French (straight, sweet). B. Italian Anise (natural size). (After Umney.)

Fennel Fruits: 1, French (bitter); 2, Indian; 3, Russian; 4, French (sweet); 6, German; 7, Japanese; 8, Persian; 9, Galician. Italian Anise, 5. (After Umney.)

somewhat distichous, and the number of rays in the umbel only from 6 to 8. It is also a much smaller plant, being only about a foot high; its flowers appear earlier; and its young sweet shoots or turiones are eaten in Italy boiled or as a salad.

The roots of fennel were formerly employed in medicine, but are generally inferior in virtues to the fruit, which is now the only official portion. It is stated that manufacturers of the oil usually distil the whole plant. Commerce is partly supplied from the product of our own gardens; but much the larger portion of the medicine is imported from Europe, and chiefly, we have been informed, from Germany. During the winter of 1879 much of the seed in the German market was adulterated with fennel-seed partially deprived of its oil. The fennel-seed

cultivated here is sweeter and more aromatic than that from abroad, probably in consequence of its greater freshness. Fennel-seeds (half-fruits) are oblong oval, from one to three or four lines in length, flat on one side, convex on the other, not infrequently connected by their flat surfaces, straight or slightly curved, brownish or of a dark grayish-green color, with five prominent, obtuse, yellowish ribs or ridges on the convex surface. On section the vittæ, or oil-tubes, are seen to be very well developed and to be situated one between each pair of ridges and two upon the flat face of each mericarp.* There are eight chief varieties of fennel known to European commerce, the fruits differing very much in size and considerably in taste. The accompanying table, originally compiled by J. C. Umney, and the illustrations (p. 640), represent sufficiently for the purposes of identification these different varieties.

Fennel Fruits.

Variety.	Average Length.	Average Length of Vittæ in Transverse Section.	Average Breadth of Vittæ in Transverse Section.	Percentage of Oil.	Odor and Taste of Oil.
	Mm.	Mm.	Mm.		
1. French (sweet)	7–8	·11	·04 to ·05	2·1	Sweet, anise-like, and fatty.
2. French (bitter)	4–5	·18 to ·2	·07 to ·08	Not distilled	. . . . .
3. German (Saxon)	8–10	·2 to ·22	·07 to ·08	4·7	Sweet and very camphoraceous.
4. Indian	6–7	·1	·03 to ·04	·72	Sweet and anise-like.
5. Russian	4–5	·2	·04 to ·05	4·8	Very camphoraceous.
6. Galician	5–6	·2 to ·22	·08 to ·10	4·4	Very camphoraceous.
7. Persian	6–7	·15	·05	1·7	Sweet and anise-like.
8. Japanese	3–4	·15 to ·16	·07 to ·08	2·7	Very sweet and camphoraceous.

Schimmel & Co.'s Semi-Annual Report for April, 1897, gives as additional varieties of fennel —Aleppo, oil amounting to 0·75 per cent.; Macedonian, 3·4 to 3·8 per cent.; Moravian, 4 per cent.; Milanese, 4·2 per cent.; Roumanian, 4·6 per cent.; Spanish, amount not stated; and Syrian (Damascus), 1·6 per cent. Of these, the Syrian may be the same as that called Persian by Umney, and the Roumanian the same as that called Russian.

The odor of fennel-seed is fragrant, its taste warm, sweet, and agreeably aromatic. It yields its virtues to hot water, but more freely to alcohol. The essential oil may be separated by distillation with water. (See *Oleum Fœniculi.*) From 960 parts of the seed Neumann obtained 20 parts of volatile and 120 of fixed oil.

Medical Properties and Uses. Fennel-seed was used by the ancients. It is one of our most grateful aromatics, and in this country is much employed as a carminative, and as a corrigent of other less pleasant medicines, particularly senna and rhubarb. It is recommended for these purposes by the absence of any highly excitant property. An infusion may be prepared by introducing two or three drachms of the seeds into a pint of boiling water. The dose of the bruised or powdered seeds is from a scruple to half a drachm (1·3–1·95 Gm.). In infants the infusion is frequently employed as an enema for the expulsion of flatus.

FRANGULA. U. S. Frangula. [Buckthorn.]

(FRĂN'GŪ-LĄ.)

"The bark of Rhamnus Frangula, Linné (nat. ord. Rhamneæ), collected at least one year before being used." *U. S.*

Rhamni Frangulæ Cortex, *Br.* (1885); Frangula Bark; Alder Buckthorn; Cortex Frangulæ, *P. G.;* Bourdaine, Bourgène, *Fr.;* Faulbaumrinde, *G.*

* Mrs. L. R. Stowell states that the centres of the prominent ridges of fennel fruit are small vascular bundles, surrounded by large clear cells, of which those near the vascular bundles are elongated and narrow, whilst those more distant are irregular in shape and have large oval communicating openings.

R. frangula. Linn. *B. & T.* 65.—*Frangula vulgaris.* Reichert. The *Alder Buckthorn* is an erect glabrous shrub from ten to fifteen feet high, without thorns, with broadly ovate obtuse leaves, with the margins entire or slightly sinuate, the under side sometimes slightly downy, and the rather numerous lateral veins diverging equally almost from the whole length of the midrib. Flowers all hermaphrodite, two or three together in each axil, with the calyx, teeth, petals, and stamens in fives. Fruit dark purple, the size of a pea. This plant grows in hedges and bushy places throughout Europe and Russian Asia, except in the far north.

Frangula bark. *t*, bast-parenchyma; *s*, bundles of bast-cells. (After Berg.)

It is probable that most of the species of the genus Rhamnus have cathartic properties. An article upon *R. purshiana* will be found on page 1158, as it is official in both of the Pharmacopœias. The *R. catharticus*, Linn., or common buckthorn, grows in Europe along with the official species, and has become naturalized in this country. Its bark is probably often sold for the official article. It is distinguished by its more spreading, thorny habit, and its diœcious flowers, which are thickly clustered in the axils and have their parts in fours. The leaves also are more acute, have their margins finely serrate and their lateral veins mostly proceeding from the proximal half of the midrib. The fruit is black.*

Properties. This bark is officially described as "quilled, about 1 Mm. thick; outer surface grayish-brown, or blackish-brown, with numerous small, whitish, transversely-elongated lenticels; inner surface smooth, pale brownish-yellow; fracture in the outer layer short, of a purplish tint; in the inner layer fibrous and pale yellow; when masticated, coloring the saliva yellow; nearly inodorous; taste sweetish and bitter." *U. S.*

According to Prof. Schrenk (*Amer. Drug.*, April, 1887), the bark of *Rhamnus frangula* can be distinguished from that of *R. purshiana* (*Cascara Sagrada*) by the absence of the irregular angular sclerenchymatous cells, which in *R. purshiana* are wedged together in large compact groups, increasing in size and number towards the surface, and causing the short fracture of the outer bark.

It is not certainly known which of the several bodies isolated from frangula bark is the purgative principle. The most important body, *frangulin*, the *rhamnoxanthin* ($C_{20}H_{20}O_{10}$) of Buchner and Binswanger, may be obtained by Phipson's process by macerating the bark for three or four days in carbon disulphide, then permitting the liquid to evaporate, exhausting

* The berries, which are ripened in September, are of the size of a pea, round, somewhat flattened at top, black, smooth, shining, with four seeds in a green, juicy parenchyma. Their odor is unpleasant, their taste bitterish, acrid, and nauseous. Their blackish, expressed juice was formerly recognized in the Br. Ph. under the name of *Rhamni Succus*. It has the color, odor, and taste of the parenchyma, is reddened by the acids, and from deep green is rendered light green by the alkalies. Upon standing it soon begins to ferment, and becomes red in consequence of the formation of acetic acid. Evaporated to dryness, with the addition of lime or an alkali, it forms the color called by painters *sap-green*. The dried fruit of another species, *R. infectorius*, yields a rich yellow color, and is employed in the arts under the name of *French berries*. M. Fleury obtained a peculiar crystallizable principle, *rhamnin*; but he did not ascertain whether it possessed cathartic properties. (See *Journ. de Pharm.*, xxvii. 666.) Winckler obtained from the ripe fruit a principle which he called *cathartin*, and believes that the rhamnin of Fleury, which was obtained from the unripe berries, is converted into that principle and grape sugar as the fruit matures. (*Chem. Gaz.*, viii. 232.) Lefort (*Journ. de Pharm.*, 1866, p. 420) studied Fleury's rhamnin, and describes it as forming pale yellow, translucent tables. It is scarcely soluble in cold water, soluble in hot alcohol, insoluble in ether or carbon disulphide. It is very soluble in caustic alkalies, from which it is precipitated by mineral acids. He gives it the formula $C_{12}H_{12}O_5 + 2H_2O$. Lefort also found a principle, *rhamnegin*, soluble in cold water, but otherwise agreeing in properties with rhamnin. Schützenberger (1868) decomposed rhamnegin, proving it to be a glucoside, having the formula $C_{24}H_{32}O_{14}$, and yielding *rhamnetin*, $C_{12}H_{16}O_5$, and a sugar isomeric with mannite. Schützenberger also found a body isomeric with rhamnegin, and distinguished the two as *α rhamnegin* and *β rhamnegin*, which, with Lefort's rhamnin, are present in buckthorn juice. Liebermann and Hörmann (*Ber. Chem. Ges.*, xi. (1878), pp. 952, 1618) confirm Schützenberger's results, and give the name of *xanthorhamnin* to his α rhamnegin. They find his formula $C_{12}H_{10}O_5$ for rhamnetin to be correct, but get results that give for xanthorhamnin rather the formula $C_{48}H_{66}O_{29}$. Both the berries and their expressed juice are active hydragogue cathartics, apt to cause nausea and severe griping, and at one time much used in dropsy and also in rheumatism and gout. The dose of the recent berry is said to be about a scruple (1·3 Gm.), of the dried a drachm (3·9 Gm.), and of the expressed juice a fluidounce (30 C.c.).

Among other species of Rhamnus which have claimed attention are *R. wightii*, a common shrub of Madras and Bombay (*P. J. Tr.*, Feb. 1888), and *R. humboldtiana*, of Mexico, which Dr. S. E. Sosa states sometimes produces paralysis in children (*El Estudio*, 1890).

the residue with alcohol, which leaves the fatty matter behind, evaporating the alcoholic liquid to dryness, and recrystallizing from ether. As thus obtained it is in fine yellow crystals, melting at about 226° C. (438·8° F.), and subliming in golden-yellow needles. It is insoluble in water, soluble in 160 parts of warm 80-per-cent. alcohol, nearly insoluble in cold alcohol, soluble in hot fixed oils, benzin, and oil of turpentine. It communicates its color to cotton, silk, and wool. Faust (*Archiv d. Pharm.*, 187, 8) first proved the glucosidal character of frangulin by boiling it in alcoholic solution with hydrochloric acid, obtaining glucose and *frangulinic acid*, $C_{14}H_8O_4$. This forms fine microscopic needles of reddish color, fusing at 248°–250° C. Liebermann and Waldheim (*Ber. Chem. Ges.*, 9, p. 1775) obtained in this decomposition instead of frangulinic acid *emodin*, $C_{15}H_{10}O_5$, which they consider to be trioxymethylanthraquinone. Frangulinic acid, on the other hand, would be a dioxyanthraquinone and an isomer of alizarin. Schwabe, in 1888, also found that *emodin* and *rhamnodulcite* were the decomposition products of *frangulin*, to which latter he gave the formula $C_{21}H_{20}O_9$, instead of that given above by Buchner. (Planchon et Collin, *Drogues Simples* (1896), vol. ii. 590.)

Medical Properties. In its fresh state this drug is very irritant to the gastro-intestinal mucous membrane, producing, when taken in sufficient quantity, violent catharsis, accompanied by vomiting and much pain. During drying it is said to lose much of its irritant powers, and the dried bark is affirmed to resemble rhubarb in its action: hence the direction of the British Pharm. 1885 that the bark should be at least one year old. A *decoction* (half an ounce to the half-pint) may be used in tablespoonful doses, or a dessertspoonful of an *elixir*, four fluid-ounces of the fluid extract to twelve of elixir of orange, or the official fluid extract in doses of from fifteen to thirty minims (0·9 to 1·9 C.c.).

GALBANUM. Br. Galbanum.

(GĂL'BĄ-NŬM.)

"A gum-resin obtained from Ferula galbaniflua, Boiss. and Buhse, and probably from other species." *Br.*

Gummi-Resina Galbanum; Galban, Mutterharz, *G.*; Galbano, *It.*, *Sp.*

It is uncertain from what plant galbanum is derived. At one time it was supposed to be the product of *Bubon galbanum*, an umbelliferous plant of the eastern coast of Africa. It has also been referred to the *Ferula ferulago* of Linnæus, the *Ferula galbanifera* of Lobel, which inhabits the coast of the Mediterranean and is found also in Transylvania and the Caucasus. But no part of either of these plants has the odor of galbanum; and it is, therefore, scarcely probable that they yield the drug. Mr. Don, having found the seeds taken from a parcel of galbanum to belong to an undescribed genus of umbelliferous plants, and concluding that they came from the same source as the gum-resin itself, gave the title of Galbanum to the new genus, and named the species *Galbanum officinale*. This was rather hastily adopted by the London College: it is by no means certain that the same plant produced the seeds and the gum-resin. Specimens of a plant were received in England from Persia having a concrete juice adhering to them, which was taken by Dr. Lindley for galbanum; and that botanist, finding that the plant belonged to an undescribed genus, named it *Opoïdia*, with the specific name *galbanifera*. Dr. Pereira, however, found the substance not to be galbanum; and this supposed origin of the drug, therefore, must be considered as extremely doubtful. A German traveller, F. A. Buhse, who has resided in Persia, states that in 1848 he met with the *galbanum* plant on the declivities of the Demavend, near the southern coast of the Caspian. He saw the gum-resin exuding spontaneously from the plant, and was informed by the natives that the drug was collected from it. The plant is a Ferula, and has received the name of *F. galbaniflua*, Boissier and Buhse. Buhse also states that the Persian galbanum is yielded by a second plant, which is doubtfully distinct from *F. galbaniflua;* this is the *F. rubricaulis*, Boissier (*F. erubescens*, Berg). Mr. Holmes is of the opinion (*P. J. Tr.*, 1891, 194) that "Levant" galbanum is yielded by *Ferula galbaniflua* and its variety *β-Ancheri;* that *solid* "Persian" comes possibly from *F. Schair*, Borsez; while the *liquid* "Persian," judging from the fruits found in it, is derived from an undescribed species allied to *F. galbaniflua*. It would also appear that the *F. galbanum* of Aitchison is not identical with that of Boissier, and that neither this species nor *F. rubricaulis* yields galbanum; and that, further, all the varieties of galbanum of commerce come through Persia. Galbanum is said to be obtained by making incisions into the stem, or cutting it off a short distance above the root. A cream-colored juice exudes, which concretes upon exposure to the air. A portion of juice also exudes spontaneously from the joints, and

hardens in the shape of tears. It was formerly official in the U. S. Pharmacopœia, but was dropped in the 1890 revision.

Properties. Galbanum usually appears in the form of masses composed of whitish, reddish, or yellowish tears, from the size of a pin's head to that of a pea and larger, irregularly agglutinated by a darker-colored yellowish-brown or greenish substance, more or less translucent, and generally mixed with pieces of stalk, seeds, or other foreign matters. It is also found, though rarely, in our markets, in the state of distinct roundish tears, about as large as a pea, of a yellowish-white or pale brownish-yellow color, shining externally as if varnished, translucent, and often adhering together. Galbanum has in cool weather the consistence of firm wax, but softens in summer, and by the heat of the hand is rendered ductile and adhesive. At 100° C. (212° F.) it is sufficiently liquid to admit of straining; and it generally requires to be strained before it can be used. A dark-brown or blackish color, a consistence always soft, the absence of whitish grains, a deficiency in the characteristic odor and taste, and the intermixture of earthy impurities are signs of inferiority. According to Hirschsohn (*Pharm. Zeit. f. Russl.*, 1893, 353), galbanum of commerce differs from that formerly found in the market; its consistence is now like that of white turpentine, although the odor is still that of Levant galbanum; the greatest difference is shown in the action of strong acids and solvents on it. (See *A. J. P.*, 1893, 384.)

The odor of galbanum is peculiar and disagreeable; its taste bitterish, warm, and acrid; its sp. gr. 1·212. Triturated with water, it forms an imperfect milky solution, which on standing deposits the greater portion of what was taken up. Wine and vinegar act upon it in a similar manner. Alcohol dissolves a considerable proportion, forming a yellow tincture, which has the smell and taste of galbanum, and becomes milky with water, but affords no precipitate. In dilute alcohol it is wholly soluble, with the exception of impurities. Ether dissolves the greater portion. "When moistened with alcohol, galbanum acquires a purple color on the addition of a little hydrochloric acid." *U. S.* 1880. According to Conrady, the composition of galbanum is: ethereal oil, 9·5 per cent.; resin, soluble in alcohol, 63·5 per cent.; and gum and impurities, 27 per cent. The purified resin was found by Conrady to contain about 20 per cent. of combined *umbelliferone*, about 0·25 per cent. of free umbelliferone, and about 50 per cent. of *galbaresino-tannol*. This latter representative of the class of resino-tannols first established by Tschirch was proved to have the alcohol character by forming the acetyl and benzoyl derivatives. Conrady also considers that the umbelliferone is combined with this galbaresino-tannol in the form of an ester. The volatile oil he found to consist essentially of a hydrocarbon of the formula $C_{10}H_{16}$, with small amounts of a sesquiterpene, $C_{15}H_{24}$. When the oil is extracted by solvents it is free from acid reaction, but when distilled with steam it acquires an acid reaction, and notable quantities of isovaleric acid are developed. These fatty acids are probably bound up as esters in the cold extracted oil. (*Archiv d. Pharm.*, 232 (1894), 98.) The crude oil is dextrogyrate. The resin, constituting about 60 per cent., is very soft, and dissolves in ether or in alkaline liquids, even in milk of lime, but only partially in carbon disulphide. When heated with hydrochloric acid for some time, it yields umbelliferone, $C_9H_6O_3$, which may be dissolved from the acid liquid by means of ether or chloroform, and obtained on evaporation in colorless acicular crystals. The aqueous solution of umbelliferone exhibits, especially on addition of an alkali, a brilliant blue fluorescence, which is destroyed by an acid. If a small fragment of galbanum be immersed in water, a fluorescence will be produced by a drop of ammonia. Asafetida shows the same reaction, but ammoniac does not.

Galbanum submitted to dry distillation yields a thick oil of brilliant blue color. This oil on rectification yields a greenish portion, and then a superb blue oil. Kachler (*Ber. Ch. Ges.*, 1871, p. 36) found a colorless oil, $C_{10}H_{16}$, and a blue oil, $C_{10}H_{16}O$, boiling at 289° C. The blue oil, according to Kachler, after purification, agrees with the blue oil of the flowers of *Matricaria chamomilla*. By fusing galbanum resin with potash, Hlasiwetz and Barth (*Ann. Ch. Pharm.*, 130, p. 354) obtained *resorcin*, together with acetic and volatile fatty acids.

According to Ludewig, a gum-resin, designated as *Persian galbanum*, is received in Russia by the way of Astrakhan or Orenburg, and is the kind used in that country. It comes enclosed in skins, and is in masses of a reddish-brown color with whitish streaks, of a disagreeable odor, somewhat like that of asafetida, and of an unpleasant, bitter, resinous taste. It is so soft as to melt with a slight elevation of temperature. It differs from common galbanum in its odor, in its color, which is never greenish, and in the absence of tears, and is probably derived from a different plant. It abounds in impurities. This variety of galbanum is probably the same as that obtained by Dr. Aitchison in Afghanistan, which on chemical examination yielded—

volatile oil, 3·108 per cent.; resin (ether extractive, 61·2, alcohol extractive, 7·576), 68·776; water extractive (gum), 17·028; insoluble matter, 10·56. (*P. J. Tr.*, Dec. 11, 1886.)

Medical Properties and Uses. Galbanum was known to the ancients. It is stimulant, expectorant, and antispasmodic, and is considered as intermediate in power between ammoniac and asafetida. It has chiefly been used in chronic affections of the bronchial mucous membrane, *amenorrhœa*, and chronic *rheumatism*. It is occasionally applied externally as a plaster to *indolent swellings*, with the view of promoting resolution or suppuration. The dose is from ten to twenty grains (0·65–1·3 Gm.), and may be given in pill, or triturated with gum arabic, sugar, and water, so as to form an emulsion.

GALLA. U. S., Br. Nutgall. [Galls.]

(GĂL'LĄ.)

"An excrescence on Quercus lusitanica, Lamarck (nat. ord. Cupuliferæ), caused by the punctures and deposited ova of Cynips Gallæ tinctoriæ, Olivier (class, Insecta; order, Hymenoptera)." *U. S.* "Excrescences on Quercus infectoria, Olivier, resulting from the puncture and deposition of an egg or eggs of Cynips Gallæ tinctoriæ." *Br.*

Gallæ, *P. G.*; Gale Halepense, vel Hercica, vel Levantica, vel Tinctoria, vel Quercina; Galle de Chêne, Noix de Galle, *Fr.*; Gallăpfel, *G.*; Galla, *It.*; Agallas de Levante, *Sp.*

Many plants, when pierced by certain insects, particularly those of the genus *Cynips*, are affected at the points of puncture with a morbid action, resulting in excrescences, which, as they are derived from the juices of the plant, partake more or less of its chemical character. Most of the oaks are occasionally thus affected; and the resulting excrescences, having in a high degree the astringency of the plant, have been employed for various practical purposes. They are known by the name of *galls*, a term which, as well as their use in medicine, has been handed down from the ancients. *Quercus infectoria*, *Q. ægilops*, *Q. excelsa*, *Q. ilex*, *Q. cerris*, and *Q. robur* have been particularized as affording this product; but it is now generally admitted, on the authority of Olivier, that the official galls are derived chiefly, if not exclusively, from *Q. infectoria*.*

Quercus infectoria. Willd. *Sp. Plant.* iv. 436; Olivier, *Voy. Orient.* t. 14 *et* 15; Carson, *Illust. of Med. Bot.* ii. 40, pl. 85. The *dyer's oak* is a small tree or shrub, with a crooked stem, seldom exceeding six feet in height. The leaves are obtusely toothed, smooth, of a bright-green color on both sides, and stand on short footstalks. The acorn is elongated, smooth, two or three times longer than the cup, which is sessile, somewhat downy, and scaly. This species of Quercus grows, according to Olivier, throughout Asia Minor, from the Archipelago to the confines of Persia. Captain M. Kinnier found it also in Armenia and Kurdistan; General Hardwicke observed it growing in the neighborhood of Adwanie; and it probably pervades the middle latitudes of Asia.

The gall originates from the puncture of the *Cynips quercûsfolii* of Linnæus, the *Diplolepis gallæ tinctoriæ* of Geoffroy, a hymenopterous insect or fly, with a fawn-colored body, dark antennæ, and the upper part of its abdomen shining brown. The insect pierces the shoots and young boughs, and deposits its egg in the wound. This irritates the part, and a small tumor quickly rises, which is the result of a morbid growth, exhibiting various cells under the microscope, but no proper vegetable fibre. The egg grows with the gall, and is soon converted into

* Under the name of *Chinese galls*, a product has been brought from China, supposed to be caused by an insect allied to the aphis, as such an insect has been found in the interior of them. They are irregularly spindle-shaped, often more or less bent, with obtusely pointed protuberances, about two inches long by an inch in diameter at the central thickest part, of an ash color and a soft velvety feel, very light, hollow, with translucent walls about a line in thickness, of a slight odor recalling that of ipecacuanha, and a bitter astringent taste. From an examination of fragments of leaves and petioles found among these galls, Dr. Schenck concluded that the tree on which they are found is a species of Rhus; but according to M. Decaisne, professor at the Museum of Natural History in Paris, their true source is probably the *Distylium racemosum* of Zuccarini (*Flor. Japon.*, i. p. 178, t. 94), a large tree of Japan, the leaves of which produce a velvety gall, resembling the one in question. (Guibourt, *Hist. Nat. des Drogues*, 1850, iii. 703.) More recently, however, it has been asserted by Mr. Daniel Hanbury that this opinion of Decaisne is erroneous (*P. J. Tr.*, Feb. 1862, p. 421), as in his examination of the packages imported from China and Japan he has found remains of different parts of a species of Rhus, but never any of a Distylium. Besides, the form of the galls of the Distylium, as figured by Siebold and Zuccarini, is entirely different. The species of Rhus which yields the commercial Chinese galls is the *R. semi-alata*. (Murray.) The Chinese make great use of this product both in dyeing and as a medicine. L. A. Buchner, Jr., has found it to contain 65 per cent. of tannic acid identical with that of the official galls. (*Pharm. Centralblatt*, July, 1851, p. 526.) It is recommended by Stenhouse for the manufacture of gallic acid, being preferable for this purpose to the official galls, in consequence of its less amount of coloring matter. (*P. J. Tr.*, Dec. 1862.) An inferior kind of galls is produced in great quantities in England, by the attack of the *Cynips kollari* of Hartig, upon the common English oak; but they have been ascertained to contain little tannic acid, and are of little value.

a larva, which feeds upon the vegetable matter around it, and thus forms a cavity in the centre of the excrescence. The insect at length becomes a fly, and escapes by eating its way out. The galls are in perfection when fully developed, before the egg has been hatched or the fly has escaped. Collected at this period, they are called, from their dark color, *blue*, *green*, or *black galls*, and are most highly esteemed. Those which are gathered later and have been injured by the insect are *white galls*. They are usually larger, less heavy and compact, and of a lighter color than the former.

The galls collected in Syria and Asia Minor are brought to this country chiefly from the ports of Smyrna and Trieste, or from London. As they are produced abundantly near Aleppo, it has been customary to designate them by the name of that town; though the designation, however correct it may formerly have been, is now wholly inapplicable, as they are obtained from many other places, and the produce of different parts of Asiatic Turkey is not capable of being discriminated, at least in our markets. Great quantities of galls, very closely resembling those from the Mediterranean, have been brought to the United States from Calcutta. Dr. Royle states that they are taken to Bombay from Bussorah through the Persian Gulf. We are, nevertheless, informed that galls are among the products of Moultan. Those of France and other southern countries of Europe have a smooth, shining reddish surface, are little esteemed, on account of their small yield of tannin, and are seldom brought to the United States.

Properties. Galls are nearly round, from the size of a pea to that of a very large cherry, with a surface usually studded with small tuberosities, in the intervals of which it is smooth. The best are externally of a dark bluish or lead color, sometimes with a greenish tinge, internally whitish or brownish, hard, solid, brittle, with a flinty fracture, a striated texture, and a small spot or cavity in the centre, indicating the presence of the undeveloped or decayed insect. Their powder is of a light yellowish gray. Those of inferior quality are of a lighter color, sometimes reddish or nearly white, of a loose texture, with a large cavity in the centre, communicating externally by a small hole through which the fly has escaped. The U. S. P. directs that "light, spongy, and whitish-colored Nutgalls should be rejected," but allows "in the centre a cavity containing either the partly developed insect, or pulverulent remains left by it," and therefore permits white galls of good quality. Galls have a bitter, very astringent taste, and when whole are inodorous or nearly so, but bruised or in powder they have a decided and peculiar though not very strong smell. The tannin of galls, usually known as *gallo-tannic acid*, appears to exist in the galls, in part at least, as a glucoside, but one very easily broken up by ferments like pectase into glucose and *di-gallic acid*, $C_{14}H_{10}O_9$, which is the material, therefore, extracted from the galls. This di-gallic acid may be considered as the anhydride of *gallic acid*, $C_7H_6O_5$, formed from two molecules of this latter by the elimination of one molecule of water. Commercial tannin yields from 0 to 22 per cent. of glucose, showing the presence of varying amounts of the unaltered glucoside. Galls yield, on an average, from 65 to 77 per cent. of tannin. (See *Acidum Tannicum* and *Acidum Gallicum*, pages 98 and 48; see also "The Tannins," by Henry Trimble, J. B. Lippincott Co., 1892.) All the soluble matter of galls is taken up by forty times their weight of boiling water, and the residue is tasteless. Alcohol dissolves seven parts in ten, ether five parts. (*Thomson's Dispensatory.*) A saturated decoction deposits upon cooling a copious pale-yellow precipitate. The infusion or tincture affords precipitates with sulphuric and hydrochloric acids, lime water, and ammonium and potassium carbonates, with solutions of lead acetate and subacetate, copper and iron sulphates, silver and mercury nitrates, and potassio-antimonyl tartrate; with solution of gelatin; and with the infusions of Peruvian bark, columbo, opium, and many other vegetables, especially those containing alkaloids, with most of which tannic acid forms insoluble compounds. The infusion of galls reddens litmus paper, is rendered orange by nitric acid, milky by mercuric chloride, and has its color deepened by ammonia, but yields no precipitate with either of these reagents. Zinc sulphate was said by Dr. A. T. Thomson to slowly occasion a precipitate, but this result was not obtained by Dr. Duncan. Infusion of galls is rendered more permanent by the addition of 10 per cent. of glycerin.

A variety of galls was imported into Germany, which was said to be derived from Central Asia, especially from the provinces of Khokan, Khiva, and Bokhara, where they are used in dyeing. They are of various forms, some being long, others round, cylindrical, or angular; and sometimes they are grouped upon a single stalk, and covered with little elevations. They differ from all other galls by their color, being on one side yellow, and on the other of a fine red. Most of them present a little opening; and in the interior are eggs and larvæ of a pe-

culiar species of aphis. They have yielded, on analysis, 43·10 per cent. of tannin, 3·03 of a green wax, 16 of cellulose, and an undetermined quantity of fecula and volatile oil. (R. Palne, *Journ. de Pharm.*, Avril, 1873.)

Medical Properties and Uses. Galls are powerfully astringent, but are no longer used internally.*

GELATINUM. Br. Gelatin.

(JĔ-LĂT'Ĭ-NŬM.)

Gelatine; Gallerte, *G.*

"The air-dried product of the action of boiling water on such animal tissues as skin, tendons, ligaments, and bones." *Br.*

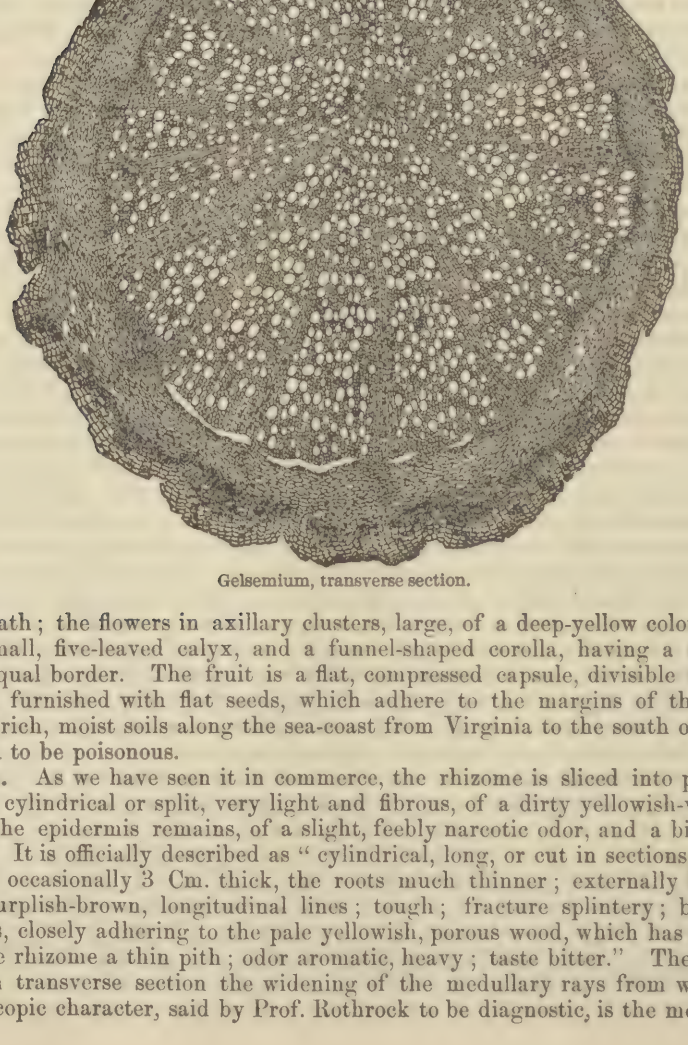
Gelatin is the term applied to purified forms of the substance ordinarily known as glue, and the bones and animal matter from which the best qualities of gelatin are prepared are carefully selected so as to be free from decomposed products and odorous substances. The hot solution of gelatin must be thoroughly clarified if the so-called sparkling gelatin is to be made. The surface of sheet gelatin is covered with lozenge-shaped marks, due to impressions left by the knotted netting upon which it is dried. Shred gelatin is made by cutting sheet gelatin into very narrow shreds by a shearing-machine. (See *Nat. Drug.*, 1894, 134.) *Gelatose* and *Paragelatose* are terms used by Dastre and Floresco to define gelatin which has lost its power of "gelatinization" through the action of ferments or microbes, saline solutions, or the prolonged action of boiling water. (*P. J. Tr.*, 1895, 454.)

It is officially described as "In translucent and almost colorless sheets or shreds. A solution in 50 parts of hot *water* is inodorous, and solidifies to a jelly on cooling. Gelatin is insoluble in *alcohol* (90 per cent.) and *ether*. It dissolves in *acetic acid*. Its aqueous solution yields a precipitate with *solution of tannic acid*, but not with solutions of other acids, nor with *solution of alum*, *solution of lead acetate*, or *test-solution of ferric chloride*." *Br.*

Gelatin is largely used for making *capsules*. Certain medicines are so offensive to the taste, and consequently so apt to sicken the stomach, that it is highly desirable to administer them in such a way as to prevent their contact with the tongue and palate. This object is fully accomplished, so far as regards many disagreeable liquid medicines, by the use of the capsules of gelatin. A polished bulb of iron, ivory, or bone, of the size and shape of the capsules required, and connected by a slender rod with a handle, is first greased by rubbing with an oiled cloth, and then dipped into a solution of gelatin made by heating six parts of pure gelatin with one of sweetened water. Upon being withdrawn, it is held for a short time so as to allow the excess of the solution to run off, and then fixed with the handle in a board, the coated bulb being upward, until the coating becomes cold and firm. The capsule is now removed by the fingers, and further dried by exposure on a tray. A number of capsules having been prepared, they are placed each in a small cell upon a board, with their mouths upward; and the liquid they are to contain is introduced by means of a syringe with a fine point. Their mouths are then closed with a drop of the solution of gelatin applied by means of a camel's-hair pencil, which is afterwards strengthened by an additional coating, given by dipping the mouth of the capsule into the solution diluted with a little water. (*Redwood's Supplement*, p. 664.) The capsules may be made of such a capacity as to contain from ten to fifteen grains of copaiba or other liquid. Capsules are now largely used for enclosing dry powders like quinine, etc. These are ovoid in shape, and, after being filled with the powder by the pharmacist, are closed by putting upon the open end a rounded gelatin cap and pressing it down tightly. When so-called *soft capsules* are desired, a small quantity of glycerin is introduced into the gelatin mass: this makes the film elastic by preventing its drying completely.

Medical Properties. Gelatin is devoid of medical properties. It was recognized by the British Pharmacopœia solely because of its use in making the suppositories of glycerin.

* *Aromatic Syrup of Galls.* The following old formula based upon one of Dr. Physick's is still sometimes employed. Macerate for twenty-four hours half an ounce of powdered galls, two drachms of bruised cinnamon, and two drachms of bruised nutmeg, in half a pint of brandy; then percolate, and, when the liquor has ceased to pass, add enough diluted alcohol to yield half a pint of filtered liquor. Put this into a shallow capsule, suspend over it two ounces of sugar on a slip of wire gauze, and set the tincture on fire. The sugar melts with the flame, and falls into the liquid beneath. When the combustion ceases, agitate and filter. A highly astringent aromatic syrup is obtained, a fluidrachm of which may be given in diarrhœa. (*A. J. P.*, xxvii. 416.)



GELSEMIUM. U. S. (Br.) Gelsemium. [Yellow Jasmine.]

(ĢĘL-SĔM'Ị-ŭM.)

"The rhizome and roots of Gelsemium sempervirens (Linné), Persoon (nat. ord. Loganiaceæ." *U. S.* "The dried rhizome and roots of Gelsemium nitidum, Michaux." *Br.*

Gelsemii Radix, *Br.*, Gelsemium Root, Yellow Jessamine; Jasmin sauvage, *Fr.;* Gelsemie, Giftjasmin, *G.;* Gelsemio, *Sp.*

Gelsemium sempervirens (L.), Ait. f. Britton and Brown; also Ait. f. (1811).—*Bignonia sempervirens*, L. (1753).—*Gelsemium nitidum*, Michx. (1803). The *yellow* or *Carolina jasmine* is one of the most beautiful climbing plants of our Southern States, ascending lofty trees, and forming festoons from one tree to another, and during its flowering season, in the early spring, scenting the atmosphere with its delicious odor. The stem is twining, smooth, and shining; the leaves perennial, opposite, shortly petiolate, lanceolate, entire, dark green above,

Gelsemium, transverse section.

and paler beneath; the flowers in axillary clusters, large, of a deep-yellow color, and fragrant, with a very small, five-leaved calyx, and a funnel-shaped corolla, having a spreading, five-lobed, nearly equal border. The fruit is a flat, compressed capsule, divisible into two parts, two-celled, and furnished with flat seeds, which adhere to the margins of the valves. The plant grows in rich, moist soils along the sea-coast from Virginia to the south of Florida. The flowers are said to be poisonous.

Properties. As we have seen it in commerce, the rhizome is sliced into pieces, about an inch in length, cylindrical or split, very light and fibrous, of a dirty yellowish-white color, but darker where the epidermis remains, of a slight, feebly narcotic odor, and a bitterish, not unpleasant taste. It is officially described as "cylindrical, long, or cut in sections, mostly from 5 to 15 Mm. and occasionally 3 Cm. thick, the roots much thinner; externally light yellowish-brown, with purplish-brown, longitudinal lines; tough; fracture splintery; bark thin, with silky bast-fibres, closely adhering to the pale yellowish, porous wood, which has fine, medullary rays, and in the rhizome a thin pith; odor aromatic, heavy; taste bitter." The accompanying figure shows in transverse section the widening of the medullary rays from within outward; another microscopic character, said by Prof. Rothrock to be diagnostic, is the more or less com-

plete division of the pith into four parts by plates of large, thin-walled cells. (*A. J. P.*, 1884.) For elaborate study of structure of Gelsemium, see *A. J. P.*, 1898. Gelsemium yields its virtues to water, and readily to diluted alcohol. Analyzed by Mr. Henry Kollock, it was found to contain gum, starch, pectic acid, albumen, gallic acid, fixed oil, a fatty resin, a dry acrid resin, yellow coloring matter, volatile oil, extractive lignin, a peculiar alkaloid called *gelsemine*, salts of potassa, lime, and magnesia, iron, and silica. The alkaloid, however, was not obtained sufficiently pure to admit of a full investigation of its properties. (*A. J. P.*, xxvii.) After Mr. Kollock's experiments, the alkaloid was obtained in a crystalline form, but still impure, by Prof. Maisch, from a tincture of the root, by a process of which a very brief abstract is given in *A. J. P.*, 1869, by Mr. C. L. Eberle, who in the same paper publishes the results of his own investigation. Mr. Eberle not only extracted gelsemine, but also satisfactorily established its alkaline properties, and proved that it was not contained in the wood of the root. Soon afterwards, the chemistry of yellow jasmine was more thoroughly investigated by Prof. Theo. G. Wormley. (*A. J. P.*, 1870.) He obtained pure gelsemine from the root, and a peculiar acid, which he called *gelseminic* (gelsemic) *acid.*

Gelsemic or *Gelseminic Acid.* Prof. Wormley obtains the acid from a fluid extract of the root, which is actually a concentrated tincture, by evaporating it on a water-bath to about one-eighth of its volume, adding to the residue several times its bulk of pure water, allowing the mixture to stand until the supernatant liquid is nearly or quite clear, then transferring to a filter, washing the solids well with water, and reducing the filtrate thus obtained, together with the washings, on a water-bath, to about the volume of the concentrated fluid extract. To this, filtered if necessary, hydrochloric acid is added in the proportion of a drop of the pure acid to each fluidounce of the original fluid extract; the acidulated liquid is then agitated with twice its volume of ether; and, after the liquids have separated, the ethereal portion is decanted, the aqueous liquid again agitated with a similar quantity of ether, which is in its turn decanted, and the watery part finally washed with about its volume of ether. On mixing the ethereal liquids thus obtained, and allowing them to evaporate spontaneously, the gelsemic acid is left, chiefly in the form of nearly colorless groups of crystals, together with more or less yellowish or brownish resinous matter. From this the crystals are separated by washing with a little cold absolute alcohol, which dissolves the resin, with but a little of the crystals. To purify the crystals further, they are mixed with a little hot water, and extracted from the mixture when cool by chloroform, which, on spontaneous evaporation, yields them nearly if not quite colorless. The acid, when pure, is colorless, inodorous, almost tasteless, and readily crystallizable, usually in groups or tufts of fine needles. The action of concentrated nitric acid may be considered as a test. If a drop of this acid be added to gelsemic acid or any of its salts, it forms a yellow, reddish, or red solution, which if treated with ammonia in excess becomes of a deep blood-red color, lasting for hours. The $\frac{1}{1000}$ of a grain will exhibit these changes. Caustic potassa, soda, or ammonia, added to the acid, causes it to become intensely yellow, and forms with it highly fluorescent solutions. The acid is fusible, and, at a high heat, volatilizable without change. Robbins (*Deut. Chem. Ges.*, 1876, 1182), who has also investigated gelsemic acid, states that it is identical with *æsculin* (the glucoside of the horse-chestnut), and gives it the formula $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$. Dragendorff and Schwartz both believed with Robbins that gelsemic acid was identical with æsculin. The subject was (*A. J. P.*, July, 1882) re-examined by Prof. Wormley, who found that gelsemic acid differs from æsculin in the following well-marked particulars: 1, in crystallization, the gelsemic acid crystallizing much more readily; 2, in solubility, the gelsemic acid being more soluble in ether and less soluble in water than æsculin; 3, gelsemic acid is not soluble in hydrochloric acid, while æsculin is; 4, corrosive sublimate gives a copious yellow precipitate with gelsemic acid, while it gives no result with æsculin; 5, copper sulphate and lead acetate yield precipitates with gelsemic acid differing from those of the same reagents with æsculin. The conclusion of Wormley, that they are "very different substances," has been confirmed by Coblentz. (*Proc. A. P. A.*, 1897, 225.) He found that gelsemic acid was not a glucoside, as it remained unchanged after prolonged boiling with dilute acids, no reaction with phenylhydrazine being obtainable. Robbins's reaction with Fehling's solution Coblentz explains by showing that gelsemic acid has active reducing powers upon copper, silver, mercury, and other similar metallic salts. The differences between it and æsculin may be thus summarized. Æsculin, formula $C_{15}H_{16}O_9 + 1\frac{1}{2}H_2O$, melts at 160° C.; gelsemic acid, formula $C_{13}H_{11}O_5$, melts at 206° C.; æsculin forms a penta-acetyl derivative melting at from 203°–206° C.; gelsemic acid forms a diacetyl derivative melting at 180° C.; æsculin splits up into sugar and æsculetin;

gelsemic acid does not hydrolyze; æsculin forms a bromine derivative melting at from 193°–195° C.; gelsemic acid forms a bromine derivative melting at 250° C.

Coblentz found that one part of gelsemic acid was soluble in 1490 parts of distilled water at 30° C., in 415 parts of absolute ether at 22° C., in 135 parts of chloroform at 24° C., and readily soluble in hot alcohol and glacial acetic acid.

Gelsemine. This may be obtained, according to Wormley, from the concentrated extract from which gelsemic acid has been separated by ether, by rendering it slightly alkaline with potassa (Schwartz prefers soda solution on account of the too great energy of the caustic potassa), then agitating repeatedly with chloroform, which dissolves the alkaloid with some impurities, and yields it, when evaporated at a very moderate heat, in the form of a hard, gum-like, yellowish or brownish-yellow solid. If this be treated with a little water, and acidulated with hydrochloric acid, it yields the alkaloid with some impurities to the liquid, which, if now filtered, evaporated to about one-sixteenth by volume of the original fluid extract employed, and then treated with a slight excess of caustic potassa, will give up the alkaloid in the form of a more or less white precipitate. This, upon being separated, and allowed to dry, shrinks greatly, and becomes dark. To purify it, the dry mass is powdered, and dissolved, with the aid of a few drops of hydrochloric acid, in a little water, from which the alkaloid is precipitated by a slight excess of caustic potassa, and then taken up by ether, which leaves it, on spontaneous evaporation, in the state of a very hard, brittle, and transparent mass, strongly adhering to the surface of the vessel employed. If now detached and pulverized, it forms a powder nearly or quite colorless. If still colored, it may be again treated with ether. Gelsemine was obtained in a much purer state than had been previously made by A. W. Gerrard. (*A. J. P.*, 1883, p. 258.) It is a brittle, transparent solid, crystallizing with difficulty from alcohol. Boiling water sparingly dissolves it. It softens at 38° C., and fuses at 45° C. The pure base gives no color reaction with strong nitric acid, and the mixture is scarcely changed in color by heating. Strong sulphuric acid has no apparent action upon it; but if to the mixture a little manganic oxide be added and rubbed with a glass rod a deep crimson-red is obtained, passing to green. This reaction is so delicate that it can be demonstrated with a solution of 1 in 100,000. If this reaction be performed upon the pure alkaloid, the color may be sufficiently intense to cause it to be mistaken for strychnine; but if a parallel experiment be carried on with strychnine, the two alkaloids cannot be mistaken, for the strychnine gives an intense purple, passing to red. Gerrard analyzed the alkaloid with care, and gives the formula $C_{12}H_{14}NO_2$ as its correct composition. F. A. Thompson (*Pharm. Era*, 1887, p. 3) announced the presence of a second alkaloid, which he called *gelseminine*. After obtaining a solution of the alkaloids as sulphates he agitates it with an alkali and ether; the ethereal solution is shaken with water acidulated with hydrochloric acid, and the alkaloids are converted into hydrochlorates; gelseminine hydrochlorate being easily soluble, and gelsemine hydrochlorate less soluble, the latter is deposited on standing, and may be obtained pure by repeated crystallizations. He asserts that gelseminine differs greatly in physical and chemical properties from gelsemine, but, as he had not succeeded in obtaining it absolutely pure, does not give the differences.

Medical Properties.* Gelsemium produces in the healthy adult agreeable sensations of languor, with muscular relaxation, so that the subject finds some difficulty in moving the eyelids and keeping the jaws closed. More largely taken, it occasions dizziness, dimness of vision, dilated pupil, general muscular debility, and universal prostration, reducing the frequency and force of the pulse, and the frequency of respiration. After very pronounced poisonous doses the symptoms which have just been enumerated are intensified: double or impaired vision, ptosis, dilated insensible pupils, falling of the lower jaw, loss of power of enunciation, and excessive muscular relaxation are associated with slow, labored breathing, which in some cases is interrupted by violent spells of dyspnœa; consciousness is long unimpaired, but is apt to be lost before death, and in rare cases unconsciousness has been present even although recovery followed. Of the various symptoms of gelsemium poisoning the most characteristic are the dropping of the

* Gelsemium is said to have been long popularly employed as a vermifuge in the Southern and Southwestern States; but its more valuable properties have been known but for a few years. Their discovery was accidental. A planter of Mississippi, laboring under an obstinate bilious fever, directed his servant to get a particular root from the garden and prepare a tea from it. The tea was prepared accordingly, and drunk by the invalid, who was soon afterwards affected with great prostration, and especially muscular debility, so that he could not raise a limb, but without stupor. These effects gradually passed off, and with them the fever. The servant had made a mistake in the root, and dug that of the gelsemium instead of the one intended. The planter, having made this discovery, employed the root afterwards with success upon his own plantation and in the neighborhood. The remedy passed into the hands of irregular practitioners, and was used by the "eclectic physicians" before its virtues came to the knowledge of the profession.

jaw and the ocular manifestations, combined with general muscular relaxation. The effects usually begin in half an hour, but sometimes almost at once. According to Prof. Wormley, death has occurred at periods which vary from one to seven and a half hours. Twelve minims of the fluid extract are said to have proved fatal to a boy three years old, and thirty-five drops of a tincture of the bark have caused death in one hour and a half. In several instances a drachm of the fluid extract has under treatment been recovered from. Dr. M. P. Hatfield has recorded a case in which fifteen grains of a resinoid extract of gelsemium caused death in a woman in one hour.

The treatment of poisoning by gelsemium should consist in evacuating the stomach, maintaining absolute rest in the horizontal position, keeping up the bodily temperature, if required, by external warmth, and administering spinal and arterial stimulants. We have very little experimental data as to the physiological antidotes to gelsemium. Our general knowledge indicates that morphine, atropine, strychnine, and digitalis given hypodermically should be of service in the treatment of the poisoning, and Dr. Courtright (quoted by Wormley) narrates a case in which the hypodermic injection of three grains of morphine, in divided doses, within a few moments was followed by marked improvement and recovery, although the patient had taken between one and two teaspoonfuls of the tincture of gelsemium. The combined injection of atropine and morphine probably affords the best available treatment.

Recent physiological studies, whilst by no means complete, have thrown much light upon the action of gelsemium. The muscular weakness which it causes is always associated with a depression of reflex activity, and is the result of a direct paralyzing influence upon the spinal cord, as probably is also the diminution of sensibility, the nerves and muscles not being sensibly affected by the poison. The action upon the circulation is less marked than upon the nervous system, the heart and arterial pressure not being much affected by therapeutic doses. After toxic amounts there is great depression of the circulation, which has been shown by Dr. I. Ott to be at least in part due to a direct action upon the heart. The dilatation of the pupil which is present in poisoning with the drug, and which is also produced by its local application to the eye, is probably due to a paralysis of the oculo-motor nerve; to which also may be ascribed the palsy of accommodation and of the external rectus muscle. The diseases in which the medicine has been prescribed are *intermittent*, *remittent*, *typhoid*, and *yellow fevers*, *inflammation* of the *lungs* and *pleura*, *dysentery*, *rheumatism*, *neuralgia*, *dysmenorrhœa*, *delirium tremens*, *trismus nascentium*, *chorea*, *hysteria*, and *epilepsy*. The drug is, however, not applicable to the treatment of low fevers, and is not sufficiently powerful as a cardiac depressant to be relied upon in very sthenic inflammations; its use should be chiefly restricted to spasmodic and neuralgic affections. In supraorbital *neuralgia* and in *odontalgia* it has been especially commended.

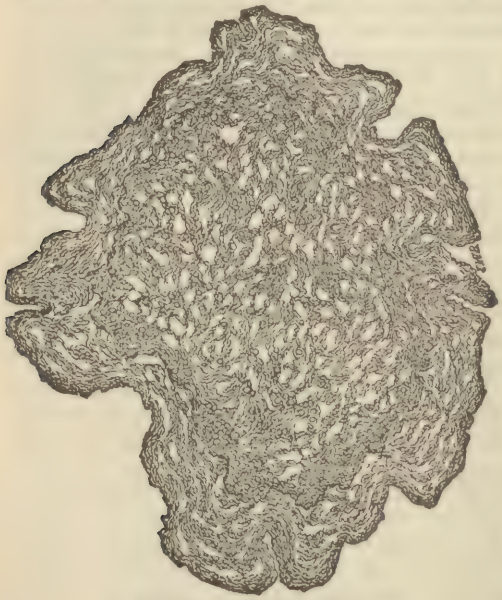
There is much testimony as to its antiperiodic properties; and it may be used as an adjuvant to quinine in the treatment of remittent fever. Dr. James D. McGarghey praises it especially in cases of intermittent, when the attacks are disposed to return obstinately and irregularly. (*Phila. Med. Times*, March 7, 1874.) It has also been employed with a measure of success in controlling cardiac palpitations.

Gelsemium should be administered in the form either of the tincture or of the fluid extract; the dose of the tincture being ten minims (0·6 C.c.), that of the fluid extract two minims (0·12 C.c.); to be repeated, if necessary, every 2, 4, or 6 hours, and be gradually increased till the object is obtained, or some obvious effect is produced on the system. The alkaloid gelsemine is exceedingly powerful. Prof. Wormley injected one-eighth of a grain into a strong cat, with the result of death in one and a half hours. He also found, as the average result of several experiments, that eight fluidounces of the fluid extract yield 3·20 grains of the pure alkaloid. On the basis of this result, the dose of gelsemine may be estimated at the 200th or 300th of a grain, supposing all the virtue of the root to reside in the alkaloid. But this estimate probably exceeds its strength, and the proper dose can be determined only by a series of carefully conducted trials.

GENTIANA. U. S. (Br.) Gentian.

(ĢĔN-TI-Ā'NA.)

"The root of Gentiana lutea, Linné (nat. ord. Gentianeæ)." *U. S.* "The dried rhizome and roots of Gentiana lutea, Linn." *Br.*



Gentianæ Radix, *Br.*, Gentian Root; Radix Gentianæ, *P. G.*; Radix Gentianæ Rubræ (vel Luteæ vel Majoris); Racine de Gentiane (de Gentiane jaune), Gentiane jaune, *Fr.*; Enzian, Enzianwurzel, Bitterwurzel, Rother Enzian, *G.*; Genziana, *It.*; Genciana, *Sp.*

Gentiana lutea. Willd. *Sp. Plant.* i. 1331; Woodv. *Med. Bot.* p. 273, t. 95; Carson, *Illust. of Med. Bot.* ii. 12, pl. 60. *Yellow Gentian* is among the most remarkable of the species which

compose this genus, both for its beauty and great comparative size. From its thick, long, branching, perennial root, an erect, round stem rises to the height of three or four feet, bearing opposite, sessile, ovate, acute, five-nerved leaves of a bright-green color, and somewhat glaucous. The lower leaves, which spring from the root, are narrowed at their base into the form of a petiole. The flowers are large and beautiful, of a yellow color, peduncled, and placed in whorls at the axils of the upper leaves. The calyx is monophyllous, membranous, yellowish, and semi-transparent, splitting when the flower opens, and reflected when it is fully expanded; the corolla is rotate, and deeply divided into five or six lanceolate, acute segments; the stamens are five or six, and shorter than the corolla. This plant grows among the Apennines, the Alps, the Pyrenees, and in other mountainous or elevated regions of Europe. The root is the only part employed.

Several other species possess analogous virtues, and are used for similar purposes. The roots of *G. purpurea* and *G. punctata*, inhabiting the same regions as *G. lutea*, and of *G. pannonica*, growing in Austria, are said to be often mingled with the official, from which they are scarcely distinguishable. The *G. macrophylla* of Pallas is used in Siberia; one indigenous species, *G. catesbæi* (now *G. Elliottii* Chapm.),* growing in the Southern States, formerly had a place in the secondary catalogue of the U. S. Pharmacopœia, and is reputed to be but little inferior to the official species. *G. quinquefolia* L. (*G. quinqueflora* Lam.), growing throughout the Northern and Northwestern States, is said to be much used in domestic practice.

Properties. As found in commerce, gentian is in pieces of various dimensions and shape, usually of considerable length, consisting sometimes of longitudinal slices, sometimes of the root cut transversely, twisted, wrinkled externally, sometimes marked with close transverse rings of a grayish-brown color on the outside, yellowish or reddish within, and of a soft, spongy texture. It is officially described as occurring "in nearly cylindrical pieces or longitudinal slices, about 25 Mm. thick, the upper portion closely annulate, the lower portion longitudinally wrinkled; externally deep yellowish-brown; internally lighter; somewhat flexible and tough when damp; rather brittle when dry; fracture uneven; the bark rather thick, separated from the somewhat spongy meditullium by a black cambium line; odor peculiar, faint, more prominent when moistened; taste sweetish and persistently bitter." *U. S.* There are no distinct pith, liber cells, starch granules, or raphides. (See *P. J. Tr.*, 1872, 42.) The odor is feeble, but decided and peculiar. The taste is slightly sweetish and intensely bitter, without being nauseous. The powder is yellowish. Water and alcohol extract the taste and virtues of the root. "Gentian Root should not yield any definite reactions with the tests for starch." *Br.*

Gentian, transverse section.

Kromayer, in 1862, first obtained the bitter principle of gentian in a state of purity, and gave it the name of *gentiopicrin*, and the formula $C_{20}H_{30}O_{12}$. It is a neutral body, crystallizing in colorless needles, which readily dissolve in water. It is soluble in spirit of wine, but in absolute alcohol only when aided by heat; it does not dissolve in ether. A solution of caustic soda forms with it a yellow solution. Under the influence of dilute acids, gentiopicrin is resolved into glucose and an amorphous yellowish-brown neutral substance named *gentiogenin*.

* *Gentiana Elliottii* Chapm. The blue gentian has a perennial, branching, somewhat fleshy root, and a simple, erect, rough stem, rising eight or ten inches in height, and bearing opposite leaves, which are ovate-lanceolate, acute, and rough on their margin. The flowers are of a palish-blue color, crowded, nearly sessile, and axillary or terminal. The divisions of the calyx are linear-lanceolate, and longer than the tube. The corolla is large, ventricose, plaited, and divided at its border into ten segments, of which the five outer are more or less acute, the five inner bifid and fringed. The number of stamens is five, and the two stigmas are seated on the germ. The capsule is oblong, acuminate, with two valves, and a single cell. *G. Elliottii* Chapm. grows in the grassy swamps from Virginia to Florida, where it flowers from September to December. It was named by Elliott (1817) in honor of Catesby. It may be given in powder in the dose of from fifteen to thirty grains, or in the form of extract, infusion, wine, or tincture.

Fresh gentian roots yield about $\frac{1}{10}$ per cent. of gentiopicrin. Another constituent is *gentianin* or *gentisin*, $C_{14}H_{10}O_5$. It forms tasteless, yellowish prisms, subliming with partial decomposition at a temperature over 300° C., sparingly soluble in alcohol, and with alkalies yields intensely yellow, crystallizable compounds, easily decomposed by carbonic acid. Von Kostanecki (*A. J. P.*, 1891, p. 192), by boiling gentisin with hydriodic acid, succeeded in demethylating it, and so obtained *gentisein*, $C_{13}H_8O_5$, which crystallizes with $2H_2O$ in fine straw-colored needles; these become anhydrous at 100° C. A triacetyl derivative was then formed from this gentisein. Gentisin is therefore the methyl ether of gentisein, and can be written $C_{13}H_5O_2\begin{cases}OCH_3\\OH\\OH\end{cases}$. Hlasiwetz and Habermann showed, in 1875, that when *gentianin* was melted with caustic potash it yielded *phloroglucin*, $C_6H_3(OH)_3$, and *oxysalicylic acid*, $C_6H_3(OH_2)COOH$. The latter was at first called *gentianic* or *gentisinic acid*. Prof. Maisch believes that tannin is absent from gentian root, and states that the dark olive-green coloration observed when ferric chloride is added to its preparations is due to gentisic acid (*A. J. P.*, 1876). Ville (*A. J. P.*, 1877) and Davies (*P. J. Tr.*, 1879) maintain that there is a small quantity of tannin in gentian root. Prof. Patch (*A. J. P.*, 1876) found that an alcoholic solution of an ethereal extract of gentian yielded a dark-green coloration with ferric salts, but if the alcoholic solution were diluted with water it yielded no precipitate with gelatin. Subsequently (*Proc. A. P. A.*, 1881) he showed there was a principle associated with the resinous matter in gentian (but which was not isolated in a state of purity) that produced the reactions of a tannin, viz., a greenish-black color with ferric chloride, and precipitates with tartar emetic, cinchonidine sulphate, and gelatin. M. Louis Magnes found in the root, when perfectly dried at 100° C. (212° F.), 15 per cent. of glucose, and 12 per cent. in the root in its ordinary state. (*A. J. P.*, pp. 333–4.) When gentian is macerated in cold water, it undergoes the vinous fermentation, in consequence of the presence of this saccharine principle. From the fermented infusion a spirituous liquor is obtained by distillation, which, though bitter and unpleasant to the smell, is said to be relished by the Swiss and Tyrolese. A. Meyer (*Pharm. Centralb.*, 1882, May) obtained a sweet principle, which he called *gentianose*, $C_{16}H_{66}O_{31}$, by precipitating the filtered juice with alcohol, treatment with ether, and crystallization from alcohol. It does not reduce Fehling's solution. Infusion of gentian is precipitated by tannic acid and the soluble salts of lead, but is compatible with the salts of iron. Pectin, so frequently found in fleshy roots, exists in gentian. (Bourquelot and Herissey, *Répert. de Pharm.*, 1898.) The yellow coloring matter of the root was investigated by E. V. Howell, who concludes that it is quercitrin.

Medical Properties and Uses. Gentian possesses in a high degree the tonic powers of the simple bitters. It excites the appetite and invigorates digestion. In very large doses, however, it is apt to oppress the stomach, to irritate the bowels, and even to occasion nausea and vomiting. It has been known from the highest antiquity, and is said to have derived its name from Gentius, a king of Illyria. Many of the complex preparations handed down from the Greeks and Arabians contain it among their ingredients; and it enters into most of the stomachic combinations employed in modern practice. It may be used in all cases of pure debility of the digestive organs, or where a general tonic impression is required. *Dyspepsia*, *atonic gout*, *amenorrhœa*, *hysteria*, *scrofula*, and *intermittent fever* are among the many affections in which it has proved useful; but it is the condition of the stomach and of the system generally, not the name of the disease, which must be taken into consideration in prescribing it; and there is scarcely a complaint in which it can be advantageously given under all circumstances. It should be administered only in the form of preparation. A syrup may be prepared by forming a saccharated infusion by means of percolation, and incorporating this at a boiling heat with simple syrup; or, perhaps more eligibly, by dissolving two drachms of the extract of gentian, and afterwards fifteen ounces of sugar, in half a pint of water. The porous property of the root causes it to expand with moisture, and it has been employed as a substitute for sponge tent in the enlargement of strictured passages.

GERANIUM. U. S. Geranium. [Cranesbill.]

(ĢĒ-RĀ'NI-ŬM.)

"The rhizome of Geranium maculatum, Linné (nat. ord. Geraniaceæ)." *U. S.*

Cranesbill Root; Racine de Bec-de-Grue tacheté, Racine de Pied-de-Corneille, *Fr.*; Fleckstorchschnabel-Wurzel, *G.*

Geranium maculatum. L. *Sp. Pl.* (1753), 681. Willd. *Sp. Plant.* iii. 705; Bigelow, *Am. Med. Bot.* i. 84; Barton, *Med. Bot.* i. 149. This plant has a perennial, horizontal, fleshy

rhizome, which is furnished with short fibres, and sends up annually an herbaceous stem, with several radical leaves. The stem is erect, round, dichotomously branched, from one to two feet high, of a grayish-green color, and thickly covered, in common with the petioles and peduncles, with reflexed hairs. The leaves are deeply divided into three, five, or seven lobes, which are variously incised at their extremities, hairy, and of a pale green color, mottled with still paler spots. Those which rise from the root are supported on footstalks eight or ten inches long; those of the stem are opposite, the lower petiolate, the upper nearly sessile, with lanceolate or linear stipules. The flowers are large, and usually of a purple color. The peduncles spring from the forks of the stem, and severally support two flowers upon short pedicels. The calyx is composed of five oblong, ribbed, cuspidate leaves; the petals are five, obovate, and entire; the stamens ten, with oblong, deciduous anthers, the five alternate filaments being longer than the others, and having glands at their base; the ovary is ovate, supporting a straight style as long as the stamens, and surmounted by five stigmas. The fruit consists of five aggregate, one-seeded capsules, attached by a beak to the persistent style, curling up and scattering the seeds when ripe. The plant is indigenous, growing throughout the United States in moist woods, thickets, and hedges, and generally in low grounds. It flowers from May to July. The root should be collected in autumn.

Properties. Geranium occurs in pieces from one to three inches long, from a quarter to half an inch in thickness, somewhat flattened, contorted, wrinkled, tuberculated, and beset with slender fibres. It is externally of an umber-brown color, internally reddish gray, compact, inodorous, and of an astringent taste, without bitterness or other unpleasant flavor. "Of horizontal growth, cylindrical, 5 to 7 Cm. long; about 1 Cm. thick; rather sharply tuberculated, longitudinally wrinkled, dark brown; fracture short, pale reddish-brown; bark thin; wood-wedges yellowish, small, forming a circle near the cambium line; medullary rays broad; central pith large; roots thin, fragile; inodorous; taste strongly astringent." *U. S.* Water and alcohol extract the virtues of geranium. According to Dr. Edward Staples, it contains tannic and gallic acids, mucilage, red coloring matter, resin, and a crystallizable vegetable principle. (*A. J. P.*, 1829, p. 171.) The Messrs. Tilden found, besides tannic and gallic acids, gum, pectin, sugar, starch, albumen, resin soluble in alcohol, oleoresin soluble in ether only, coloring matter, chlorophyll, lignin, and various salts. (*P. J. Tr.*, 1863, p. 22.) Tannic and gallic acids are probably the sole active ingredients. Henry Trimble and J. C. Peacock (*A. J. P.*, 1891, p. 265) collected the plant at periods of the year ranging from January to October, and determined the percentage of tannin as calculated for the perfectly dry drug to vary from 9·72 to 27·85 per cent. They also determined that it belonged to the class of tannins analogous to gallo-tannic acid, yielding pyrogallol on heating. They decomposed the tannin by the action of hydrochloric acid, obtaining gallic acid, glucose, and geranium red as products.

Medical Properties and Uses. Geranium is one of our best indigenous astringents, and may be employed for all the purposes to which these medicines are applicable. The absence of unpleasant taste and of other offensive qualities renders it peculiarly serviceable in the case of infants and of persons of very delicate stomach. *Diarrhœa*, *chronic dysentery*, *cholera infantum* in the latter stages, and the various hemorrhages, are the forms of disease in which it is most commonly used and with greatest advantage; but care should be taken, before it is administered, that the condition of the system and of the part affected is such as not to contra-indicate the use of astringents. As an application to *indolent ulcers*, an injection in *gleet* and *leucorrhœa*, and a gargle in relaxation of the uvula and aphthous ulcerations of the throat, it answers the same purpose as kino, catechu, and other medicines of the same class. It is a popular domestic remedy in various parts of the United States, and is said to be employed by the Indians. It may be given in substance, decoction, tincture, or extract. The dose of the powder is from twenty to thirty grains (1·3–1·95 Gm.); that of a decoction, made by boiling an ounce of the root in a pint and a half of water to a pint, from one to two fluidounces (30–60 C.c.); that of the fluid extract, from twenty to thirty minims (1·25–1·9 C.c.). The medicine is sometimes given to children, boiled in milk.

GLUSIDUM. Br. Gluside.

(GLŪ'SI-DŬM.)

"Gluside, or benzoyl sulphonimide, is a sweet imide derivable from toluene. Its constitution is represented by the formula $C_6H_4 < \begin{matrix} CO \\ SO_2 \end{matrix} > NH$." *Br.*

Saccharin; Glucusimide; Benzoyl-sulphonicimide, $C_6H_4COSO_2NH$; Anhydro-orthosulphaminbenzoic Acid; Glukusin; Neo-saccharin.

This substance, which is now official in the British Pharmacopœia additions, is one of the remarkable derivatives from coal tar. As saccharin is a trade product and controlled as a proprietary compound, the United States Pharmacopœia has not admitted it to its list. Its name is suggestive of its predominant characteristic, that of intense sweetness. Its composition is $C_6H_4 < \begin{matrix} CO \\ SO_2 \end{matrix} > NH$, and it is prepared from toluene by first converting this into the mixture of mono-sulphonic acids, which are changed into the corresponding toluene-sulphonic chlorides. The ortho compound is then acted upon by ammonia, converting it into the sulphamide, which by oxidation yields the imide, as above. It forms a white powder, melting at 200° C. with partial decomposition, evolving the odor of bitter almonds. It is soluble in water, from which it can be crystallized in alcohol ether, glycerin, and glucose. Its taste in diluted solutions is intensely sweet, so that 1 part of saccharin will sweeten quite strongly 10,000 parts of water. Saccharin may be detected in sugar solutions by extracting with ether, evaporating, and fusing the residue, which, if saccharin, will melt at about 200° C., and fused with nitre and sodium carbonate will show sulphuric acid. The weight of $BaSO_4$ obtained in this way from 100 Gm. of sugar multiplied by 0·785 will give the weight of saccharin extracted. Saccharin occurs as a white powder, composed of irregular crystals, very slightly soluble in water readily soluble in glycerin, alcohol, and ether. Its aqueous solution has a distinctly acid reaction and forms salts. Its most remarkable property is its sweet taste, which is said to be three hundred times more intense than that of sugar. The commercial product, according to Pope, frequently contains para-sulphamine-benzoic acid, from which impurity it can be freed by recrystallization, acetone being used as the solvent. Hefelman has furnished a process for assaying saccharin. (See *Proc. A. P. A.*, 1895, 701.) The difference in melting points of pure saccharin and para-sulphamine-benzoic acid is also used for distinguishing them; the former melts at 224·5° C. and the latter at 286·5° C. (*Pharm. Central.*, 1896, 279.)

The British Pharmacopœia furnishes the following characters and tests: "A light, white, minutely crystalline powder, having an intensely sweet taste in dilute solutions. When heated it fuses, and then sublimes with partial decomposition. It is soluble in 400 parts of cold *water*, in 24 parts of boiling *water*, in 25 parts of *alcohol* (90 per cent.), and but slightly in *ether* or *chloroform*. It is very soluble in diluted *solution of ammonia;* also in solution of *sodium bicarbonate*, with evolution of carbonic anhydride. A warm solution of *sodium bicarbonate*, when neutralized with Gluside and evaporated to dryness, yields 'soluble gluside' or 'soluble saccharin,' which is very soluble in *water*, 100 parts of Gluside yielding nearly 113 parts of neutral 'soluble gluside.' Neither Gluside nor soluble gluside is blackened by *sulphuric acid*, even when the mixture is gently warmed for a short time (absence of sugar, etc.). On evaporating either variety with excess of *solution of potassium hydroxide*, maintaining the residue in a state of semi-fusion for a few minutes, cooling, dissolving in *water*, faintly acidulating with *hydrochloric acid*, and adding a few drops of *test-solution of ferric chloride*, a reddish-brown or purplish color is produced. A solution of 0·5 gramme of Gluside in 80 cubic centimetres of warm *water*, set aside for 12 hours, deposits tabular crystals which melt between 426° F. and 428° F. (218·8° C. and 220° C.); and it should not, even when briskly shaken, deposit crystals melting at a higher temperature (absence of sulphamido-benzoic acid)."

Medical Properties and Uses. U. Morro and V. Aducco (*Arch. Ital. de Biolog.*, 1886, vii.) find that when a solution of saccharin is rendered neutral with soda, frogs will live in it for months; also that the injection of concentrated solutions of saccharin into the cellular tissue has no influence on the batrachian. Six hundred grains given to a dog during ten days caused no alteration in the weight or general health of the animal. A careful study failed to detect any change in the urine as to the daily excretion of water, urea, hippuric acid, or phosphoric acid. The chlorides seemed to be somewhat increased. The saccharin escaped unchanged from the kidneys, rendering the urine very sweet, and having a notable effect in delaying its putrefaction. No saccharin could be found either in the milk or in the saliva of a nursing woman to whom it was administered, and a dose of 75 grains caused no symptoms in man. These statements are confirmed by Stutzer and Salkowski (*Virchow's Archiv*, cv. p. 46), and are in accord with the general results obtained by clinicians. Saccharin is chiefly useful for the purpose of replacing sugar in *diabetes*, *obesity*, and other diseases in which sugar is contra-indicated. It is true that Plugge has found that outside of the body saccharin retards both salivary and pancreatic digestion, and Sawitzki believes that he has experimentally demonstrated that saccharin inhibits nitrogenous metamorphosis by a direct action on metabolism. Nevertheless, saccharin may be used for a great length of time without appar-

ent effect; and it is probably often employed on a large scale to sweeten glucose in the place of cane sugar. For use as a sweetener, two parts of saccharin should be incorporated with three parts of sodium bicarbonate, which renders it soluble. It is probably safer not to allow more than from twenty to twenty-five grains (1·29–1·62 Gm.) of saccharin a day.

GLYCERINUM. U. S., Br. Glycerin.

(GLĬÇ-Ē-RĪ'NŬM.)

"A liquid obtained by the decomposition of fats and fixed oils, and containing not less than 95 per cent. of absolute Glycerin [$C_3H_5(OH)_3 = 91·79$]." *U. S.* "Glycerin, or glycerol, is a trihydric alcohol, $C_3H_5(OH)_3$, associated with a small percentage of water; it is obtained by the interaction of alkalies, or of superheated steam, with fats and fixed oils." *Br.*

Glycerina, *U. S.* 1870; Glycerine; Glycerinum, *P. G.*; Glycérine, *Fr.*; Oelsüss, *G.*

In the process for making lead plaster, litharge, olive oil, and water are boiled together, when the olein of the oil is decomposed by the lead oxide, according to the following reaction: $2(C_3H_5(OC_{18}H_{33}O)_3) + (PbO)_3 + (H_2O)_3 = 2(C_3H_5(OH)_3) + 3(Pb(OC_{18}H_{33}O)_2)$, when we obtain lead oleate or plaster and free glycerin. (See *Emplastrum Plumbi.*) It follows, therefore, that the plaster, while still hot and in the liquid state, contained glycerin diffused through it. It was this process that was used for preparing glycerin in the formula of U. S. P. 1850. In accordance with this, when the liquid plaster is mixed with an equal measure of boiling water, and the mixture stirred briskly, a solution of glycerin is obtained, which, after having been decanted, and evaporated to a limited extent, is freed from lead by hydrogen sulphide. The liquid is then filtered to separate lead sulphide, heated to free it from hydrogen sulphide, and finally evaporated to expel the water, which is known to be all removed when the mass ceases to lose weight.

Glycerin was discovered in 1789 by Scheele, by whom it was called the *sweet principle of oils.* It is produced not only during the saponification of the fats and oils by lead oxide in forming lead plaster, but also during the same process when effected by potassa and soda in the manufacture of soap; the alkalies uniting with the oily acids and setting the glycerin free. Soapmakers' waste is an abundant source of glycerin; but when thus obtained it is apt to have more or less odor, which even percolation through animal charcoal does not always remove. The two methods of saponification by which glycerin has been obtained on a large scale are the process of Wilson and Payne, of decomposing the fats by superheated steam and after distillation, and the lime autoclave process of Milly. A process patented by Michaud Frères, of Paris, and operated by the Continental Glycerine Co., of New York, decomposes the fats by high-pressure steam in the presence of a small quantity of zinc oxide. The glycerin is obtained pure, and the fat acids can be saponified afterwards. The process of Mr. Richard A. Tilghman, of Philadelphia (the patent for which was obtained in 1854, and, after years of litigation, was at last sustained in 1888), consists in subjecting fatty bodies to the action of water at a high temperature under pressure, whereby the fats, which are *glycerides* or ethers of the fatty acids, are broken up into free glycerin and free fatty acids, the water supplying the elements of hydrogen and oxygen necessary for that change. The reaction is as follows for the case of a fat like stearin: $C_3H_5(OC_{18}H_{35}O)_3 + (H.OH)_3 = C_3H_5(OH)_3 + 3(C_{18}H_{35}O.OH)$. (See *A. J. P.*, March, 1855, p. 121.) Through a distillatory apparatus containing palm oil, heated steam between 550° and 600° F. is passed. The oil is decomposed into free acids and glycerin, which, together with water, distil over, and, condensing in the receiver, separate into two layers, the lower of which is glycerin. If this, as first procured, contain too much water, it must be concentrated; if discolored, it must be redistilled with vapor. (*P. J. Tr.*, 1861, p. 350.) Ordinary impure glycerin may be purified by distillation with steam under pressure. Though, when distilled alone, it is partially decomposed, giving off pungent vapors of *acrolein*, yet in a current of superheated steam it passes over unchanged at temperatures between 204·4° and 260° C. (400° and 500° F.). Very pure glycerin is now produced in the United States in immense quantities. The present annual production of raw glycerin through the world amounts to 40,000 tons, of which 26,000 tons are obtained from the stearic acid manufacture and 14,000 tons from soap manufacture. France is the largest producer, with 6000 tons from the first source and 3500 tons from the second. The United States is credited with 3000 tons from each of these two sources. The United States also imports considerable quantities of glycerin, the amounts for the last three years having been—for 1895, 13,488,825 lbs., valued at $784,613; for 1896, 21,158,829 lbs., valued at $1,472,302; for 1897, 12,717,098 lbs., valued at $1,182,099.

Properties. Glycerin is "a clear, colorless liquid, of a thick, syrupy consistence, oily to the touch, odorless, very sweet and slightly warm to the taste. When exposed to the air, it slowly abstracts moisture. Specific gravity, not less than 1·250 at 15° C. (59° F.). Soluble, in all proportions, in water or alcohol; also soluble in a mixture of 3 parts of alcohol and 1 part of ether, but insoluble in ether, chloroform, carbon disulphide, benzin, benzol, and fixed or volatile oils. Glycerin is slowly volatilized from an aqueous solution, at or above 100° C. (212° F.), with the vapor of water. Heated by itself to a higher temperature, it yields acrid decomposition products, boils at a temperature at or above 165° C. (329° F.), and is finally entirely decomposed and dissipated. If a fused bead of borax, on a loop of platinum wire, be moistened with Glycerin, and then held in the non-luminous flame, the latter will be transiently tinted deep green." *U. S.*

In properties, glycerin is intermediate between water and the oils. When exposed to the air it gradually absorbs moisture. As already stated, though decomposed by a high heat in its unmixed state, yet with water under pressure it is volatilizable unchanged at a temperature between 204·4° and 260° C. (400° and 500° F.). Cooled down rapidly, it only becomes more viscid, without congealing, even when a temperature of —40° C. is attained; but, if kept for some time at a temperature of about 0° C. (32° F.), it gradually forms hard but deliquescent crystals, which melt only at about 22° C. (71·6° F.).* This fact is now utilized as a means of concentrating and purifying glycerin. According to Mr. G. F. Wilson, glycerin, when of the density 1·24, contains 94 per cent. of anhydrous glycerin; when of the density 1·26, 98 per cent. A table by Dr. Wilhelm Lenz (*Zeitsch. f. Anal. Chem.*, 1880), showing the percentage of absolute glycerin in mixtures of glycerin and water, which was obtained by a quantitative determination of the carbon in the various dilutions by ultimate analysis, will be found in the U. S. D., 15th ed. p. 712. The following table by Prof. W. W. J. Nicol, of England, has been constructed after careful determinations, aided by Dr. A. B. Lyons's data on expansion of glycerin solutions. (*Pharm. Era*, 1888.)

Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.	Per cent. Glycerin.	Sp. Gr. at 15° C. = 59° F.

* Mr. Wm. Crookes gives an account, in the *Chem. News* of Jan. 18, 1867, of 5 tons of glycerin imported into London from Germany in casks of 8 cwt. each, which, though when it left the Continent it was in its ordinary state of a viscid liquid, was found, on reaching London, to have become solidified into a mass of very hard, brilliant crystals. The same result has been noticed in Vienna, in a mass of glycerin which had been in an iron tank more than a year. (*Chem. News*, April 5, 1867.) The crystalline mass noticed by Mr. Crookes yielded pure glycerin when melted. Frozen glycerin has been examined by Mr. Wallace Procter and Prof. Henry Trimble (*A. J. P.*, 1885, p. 273): the crystals had the sp. gr. 1·2618, and the portion which had not been solidified had the sp. gr. 1·235.

Glycerin possesses extensive powers as a solvent, and is an excellent excipient for many medicinal substances. It dissolves bromine and iodine, sulphur iodide, potassium and sodium chlorides, the fixed alkalies, some of the alkaline earths, lime, for example, for which it increases the solvent powers of water (*Journ. de Pharm.*, Juin, 1874), and a large number of neutral salts. It also dissolves the vegetable acids, particularly tannic acid. It is a good solvent of pepsin, and is used for the extraction of this principle from the mucus of the stomach. Two parts and a half of glycerin dissolve one of sugar, and three and a half parts, one of gum. When starch-paste and glycerin are heated together, a turbid liquid is formed, which deposits on cooling; the supernatant liquid holding starch in solution. (*Journ. de Pharm.*, Nov. 1868, pp. 361–2.) Prof. J. S. Blockley, of London, has ascertained that certain neutral vegetable substances are far more soluble in glycerin than in water. Thus, salicin dissolves in eight parts of cold glycerin, and santonin in eighteen parts when boiling. The latter solution, when of half this strength, forms on cooling an almost solid mass. It is not always a good solvent for alkaloids or their salts, and will *sometimes precipitate the latter even from their aqueous or acidulated solutions.* Glycerin, next to alcohol, is the best solvent of iodine. Iodine and potassium iodide, when dissolved in it, form *iodized glycerin*, the medical applications of which are given under iodine. (See *Iodum.*)* It combines with potassa and baryta, and also with sulphuric acid. Glycerin is not susceptible of becoming rancid, or of fermenting spontaneously, but will generate a portion of alcohol under the combined influence of chalk and of a ferment formed of cheese or animal tissue. During this change there is no intermediate formation of glucose, provided calcium carbonate be present. (*Berthelot.*) Glycerin does not evaporate when exposed to the air; nor can it be distilled without decomposition, unless in the presence of water or steam. When decomposed by heat, it emits extremely irritating vapors. At a full red heat it takes fire, and burns with a blue flame. In consequence of the high temperature required for its volatilization, it has been proposed to use it for an evaporating bath, in which a heat beyond that of boiling water is required. Glycerin is antiseptic, and has been recommended by Mr. Warington and M. Demarquay to preserve alimentary substances and objects of natural history, and to inject bodies for dissection. According to Dr. W. Frazer, it does not answer to keep pathological preparations, as they are completely softened by its action. M. Berthelot, of Paris, has succeeded in combining glycerin with a number of acids, both mineral and organic, forming three distinct series of neutral compounds. Among others, he has united it with the fatty acids, producing, by synthesis, the organic fatty substances stearin, palmitin, olein, etc. Glycerin has been formed artificially from tribromallyl, by Wurtz, and from trichlorhydrin, by Friedel and Silva. Synthesis is, however, not practicable on a large scale, no method having yet been discovered to compete successfully with its preparation from natural fats. By Pasteur it was ascertained to be one of the products of the vinous fermentation. Glycerin is a triatomic alcohol, being a compound of the triad radical (C_3H_5) with 3(OH) groups. In the natural fats, the three H atoms of these OH groups are replaced by fatty acid radicals like stearyl, $C_{18}H_{35}O$, palmityl, $C_{16}H_{33}O$, and oleyl, $C_{18}H_{33}O$. The natural fats are, therefore, compounds of an alcohol radical with an organic acid, and are true ethers, which are known as *glycerides.*

The solvent and preservative properties as well as agreeable taste and permanent consistence of glycerin render it very useful as a menstruum in pharmacy; and a class of preparations consisting of medicinal substances dissolved in it has come into extensive use. The British Pharmacopœia has adopted such a class, under the name of *Glycerina*, or *glycerines.* This title is not now available, because these terminations are reserved for alkaloids, while the term *glyceroles*, adopted from the French, is objectionable, as the termination has been used as

* The following table, by Klever, gives a general view of the solvent powers of glycerin,—100 parts of glycerin dissolving the annexed quantities of substances:

(*Neues Jahrb. für Pharm.*, 1869, Mai u. Juni, 315.)

designative of certain proximate principles. But the U. S. title, *Glycerita*, or *glycerites*, is satisfactory.

Impurities and Tests. Glycerin is occasionally deficient in density and consistency. According to M. Dalpiaz, it is sometimes perfectly colorless from being bleached by chlorine, when it is apt to contain calcium chloride, as well as free chlorine. The latter may be detected by rendering the suspected sample slightly blue by a few drops of an acid solution of indigo in sulphuric acid, when, if free chlorine be present, the blue color will disappear.

The Pharmacopœia furnishes the following tests: "An aqueous solution of Glycerin is neutral to litmus paper. When a small portion of Glycerin is heated to boiling in an open porcelain or platinum capsule, and then gently ignited, it should burn and vaporize so as to leave not more than a dark stain (absence of *dextrin* and *sugar*, which would leave a bulky, difficultly combustible, charred mass); and on full combustion no residue whatever should be left (absence of *fixed impurities*). If 5 C.c. of Glycerin be mixed with 50 C.c. of water and 10 drops of hydrochloric acid in a small flask, and heated for half an hour on a boiling-water-bath, then 10 C.c. of the hot liquid mixed with 2 C.c. of sodium hydrate test-solution and 1 C.c. of alkaline cupric tartrate volumetric solution, no yellowish-red cloudiness or precipitate should appear within six hours (absence of *sugars*). On gently warming a mixture of equal volumes of Glycerin and of concentrated sulphuric acid in a test-tube, the liquid should not acquire a dark color (absence of *readily carbonizable impurities*). On gradually heating 5 C.c. of Glycerin with 3 C.c. of diluted sulphuric acid in a test-tube, short of boiling, no offensive or acidulous odor should be evolved (absence of *fatty acids*, etc.). No color, cloudiness, or precipitate should appear when separate portions of its aqueous solution (1 in 10) are treated with hydrogen sulphide or ammonium sulphide test-solution (absence of *metals*), barium chloride test-solution (*sulphuric acid*), calcium chloride test-solution (*oxalic acid*), or ammonium oxalate test-solution (*calcium salts*). If a mixture of 2 C.c. of Glycerin with 10 C.c. of water, contained in a perfectly clean, glass-stoppered cylinder, be heated for five minutes in a water-bath at a temperature of 60°–65° C. (140°–149° F.), then mixed with 10 drops of silver nitrate test-solution, and the cylinder set aside, well stoppered, in diffused daylight, no change of transparency or color should occur in the mixture within five minutes (absence of *chlorides*, and limit of *impurities having reducing properties*)." *U. S.* The Br. Pharm. furnishes the following tests: "Sp. gr. 1·260. It should yield no characteristic reaction with the tests for lead, copper, arsenium, iron, calcium, potassium, sodium, ammonium, chlorides, or sulphates; and no red precipitate with excess of *solution of potassio-cupric tartrate* on boiling, even when previously acidified and boiled (absence of grape and cane sugars). It should undergo no darkening in color at ordinary temperatures when mixed with an equal volume of *solution of ammonia* and a few drops of *solution of silver nitrate;* and when shaken with an equal volume of *sulphuric acid*, the mixture being kept cool, no coloration, or only a very slight straw coloration, should result (absence of foreign organic matter). When gently heated with a mixture, in equal volumes, of *alcohol* (90 per cent.) and *diluted sulphuric acid*, a fruity odor should not be produced (absence of butyric acid). 2 cubic centimetres diluted with 5 cubic centimetres of a mixture of 1 part of *hydrochloric acid* and 7 parts of *water*, 1 gramme of pure *zinc* being added, and the whole placed in a long test-tube, the mouth of which is covered by a piece of filter-paper moistened with a drop or two of *test-solution of mercuric chloride* and dried, should not afford a yellow stain on the paper even after 15 minutes (limit of arsenium). When heated in an open capsule it yields acrid vapors; and is finally dissipated, leaving no ash (absence of fixed mineral matter)." Arsenic has been shown to exist in small quantities as an impurity in glycerin of European make (*P. J. Tr.*, 1894, 585, 588); its presence may be suspected whenever sulphuric acid (made from pyrites) has been used in the manufacture of the glycerin. Lime may be detected by ammonium oxalate; lead, by ammonium sulphide; and sulphuric acid, by a soluble salt of barium. Diluted, and boiled with a solution of potassa, it is not altered in color, showing the absence of glucose. Trommer's test is probably still more effectual. Chloroform was proposed as a test of sugar, in consequence of the complete insolubility of sugar in it, while glycerin was said to be very soluble; but subsequently chloroform was shown to be incapable of dissolving glycerin, though readily forming an even mixture, which separates into its two constituents, on standing. (*Chem. News*, Feb. 25, 1870.) The absence of sugar is shown if, upon the addition of two drops of concentrated sulphuric acid, and the application of heat, no brown discoloration is observed. (*Journ. de Pharm.*, Nov. 1863.) The late Prof. Procter believed that the most satisfactory method of detecting cane sugar is to dilute a little glycerin with three parts of water, then add a few grains of tartaric

acid, and boil for a short time. Cane sugar, if present, is thus converted into glucose, which may be detected by adding first a solution of copper sulphate, and then the solution of potassa to the heated liquid, when the formation of the reddish suboxide of copper will afford the requisite proof. (*A. J. P.*, 1867.) According to M. Hager, sugar or dextrin may be detected in the following manner. Dilute the glycerin with water, add ammonium molybdate and some drops of nitric acid, and boil. If these impurities are present, a blue color is produced; if not, it remains colorless. (*Ibid.*, May, 1869.) Among the most injurious impurities of glycerin are thought to be oxalic and formic acids, the latter of which, being especially irritating to the skin, unfits glycerin for some of the purposes for which it is most employed. The oxalic acid is said to result from the action of sulphuric acid employed in purifying glycerin; the formic, from the reaction between glycerin and oxalic acid. They may be detected by the U. S. P. tests. Mr. Henry Bower, of Philadelphia, who manufactured very pure glycerin, says that silver nitrate is the most reliable test. Glycerin which shows no reaction with this salt he considers suitable for all uses. (*A. J. P.*, 1868.) See improved U. S. P. test above. For a method of extracting glycerin from mixtures containing sugar and glucose, see a paper by Prof. Prescott, *N. R.*, 1878. For methods of determining glycerin in mixtures or its detection in wines, etc., see *Chem. News*, 1882; *A. J. P.*, 1882; *Schweiz. Wochensch. f. Pharm.*, 1881; *Chem. News*, 1886; *Amer. Drug.*, 1886.*

Medical Properties. The uses of glycerin as a vehicle for other medicines have been already given. When given internally, it is laxative, and it has also been suggested as a substitute for cod-liver oil in phthisis, etc. Dr. R. P. Cotton, however, has tried it in the Consumption Hospital at Brompton, and shown that it has generally but little influence, and that as a remedial agent it will bear no comparison with cod-liver oil. When injected directly into the blood, glycerin produces in the lower animals violent nervous symptoms and death, but this action is probably due to the mechanical alteration of the viscidity of the vital fluid. All our physiological evidence goes to show that glycerin has, unless in very immoderate quantities, no distinct physiological or therapeutic properties other than those of a feeble laxative. It has recently been extensively employed in habitual constipation in the form of suppositories. (See *Suppositoria Glycerini*.) Although at various times much lauded in tuberculous diseases and in diabetes, it has entirely failed to gain the confidence of the profession, and is now very rarely employed.

Glycerin has come into extensive use as an *external* remedy. Its emollient virtues and undrying property adapt it to the treatment of skin diseases in which a softening and soothing application is required. It appears to have been first employed externally in 1846, by Mr. Thomas De la Rue, of London, whose observation of its utility led Mr. Startin to try it in the Hospital for Skin Diseases, where it came into extensive use. The principal cutaneous diseases in which it has been found beneficial are *pityriasis*, *lepra*, *herpes*, *eczema*, *psoriasis*, *prurigo*, and *lichen*. It is a useful addition to lotions in the incrusted form of *lupus*, and in various syphilitic and strumous eruptions. It is also useful in *chapped skin* and excoriated surfaces. Added to poultices, in a proportion varying from one-fourth to one-sixteenth, it has the effect of keeping them soft for a long time. To collodion it gives a plasticity which renders it often better suited to skin affections. Incorporated in very small proportion with extracts and pills, it keeps them soft and free from mouldiness. In cases of deafness, from deficiency, accumulation, or hardness of the cerumen, and attended with dryness of the meatus, glycerin is an excellent remedy, introduced into the canal by means of raw cotton saturated with it. Glycerin may be used in the form of an ointment.†

GLYCERITA. Glycerites.

(GLĬÇ-Ē-RĪ'TĂ.)

Glycerina, *Br.*; Glycerines.

These are solutions of medicinal substances in glycerin. In the thirteenth edition of the Dispensatory various reasons were adduced for preferring the name glycerates for these preparations, but, as the revisers of the U. S. Pharmacopœia have since adopted that of glycerites,

* *Glycero-alcohol*, a valuable solvent made by mixing glycerin, 333; distilled water, 146; and alcohol sufficient to measure 1000 parts. Its specific gravity is about 1; it is a good solvent for alkaloids, keeps indefinitely, and does not evaporate readily.

† Mr. Ecky's *glycerin ointment* is made as follows. Take of spermaceti *half an ounce*; white wax *a drachm*; oil of almonds *two fluidounces*; glycerin *a fluidounce*. Melt the spermaceti and wax with the oil of almonds by a moderate heat. Then, having poured the melted liquid into a Wedgwood mortar, add the glycerin, and rub until the ingredients are thoroughly mixed and cool. This ointment may be used with advantage in chaps and excoriations.

these reasons are omitted. The U. S. name is certainly much better than the British. (See p. 658.)

Glycerin has valuable properties as a solvent and vehicle of medicinal substances. Such are its not unpleasant taste and bland character; its wide range of solvent power, which adapts it sometimes as a menstruum where neither water nor alcohol could be advantageously used, and enables it to retain in solution otherwise insoluble substances so frequently found in infusions and decoctions; and its preservative influence, which often protects against oxidation, and, by a destructive agency upon all of the lowest forms of vegetable and animal life, prevents the various fermentative processes so destructive of organic bodies. Another important property, as a vehicle for external remedies, is the permanence of its liquid character, so that it does not, like water and alcohol, dry up when applied to the skin; resembling in this respect, as well as in its demulcent quality, the fixed oils, without their tendency to rancidity. Hence it has of late come into extensive use in the preparation of medicinal solutions, which under the name of *Glycérés* found admission into the French Codex of 1866, and are now recognized by both the United States and British Pharmacopœias.*

GLYCERITUM ACIDI CARBOLICI. U. S. (Br.) Glycerite of Carbolic Acid.

(GLĬC-Ē-RĪ'TŬM ĂÇ'Ĭ-DĪ CĂR-BŎL'Ĭ-CĪ.)

Glycerinum Acidi Carbolici, *Br.,* Glycerin of Phenol; Glycérole d'Acide phénique, Glycérine phénique, *Fr.;* Phenol-Glycerit, *G.*

"Carbolic Acid, *twenty grammes* [or 309 grains]; Glycerin, *eighty grammes* [or 2 ounces av., 360 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the Carbolic Acid and Glycerin, successively, into a tared capsule, and stir them together until the Acid is dissolved. Then transfer the solution to a bottle." *U. S.*

"Phenol, 1 *ounce* (Imperial) or 20 grammes; Glycerin, sufficient to produce 5 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Triturate the Phenol with the Glycerin until solution is effected." *Br.*

For the uses of this preparation, see *Acidum Carbolicum* (p. 35). The U. S. 1890 glycerite is a 20 per cent. by weight solution; the British preparation is slightly weaker, being a 20 per cent. by volume solution. It may be used internally or locally, and for both purposes should in general be diluted with water at the time of application. The dose is from five to ten minims (0·3–0·6 C.c.).

GLYCERITUM ACIDI TANNICI. U. S. (Br.) Glycerite of Tannic Acid.

(GLĬÇ-Ē-RĪ'TŬM ĂÇ'Ĭ-DĪ TĂN'NĬ-CĪ.)

Glycerinum Acidi Tannici, *Br.;* Glycérole de Tannin, Glycérine tannique, *Fr.;* Tannin-Glycerol, *G.*

"Tannic Acid, *twenty grammes* [or 309 grains]; Glycerin, *eighty grammes* [or 2 ounces av., 360 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Weigh the Tannic Acid and Glycerin, successively, into a tared porcelain capsule, avoiding contact with metallic utensils, and apply the heat of a water-bath, until the Acid is completely dissolved. Then transfer the solution to a bottle." *U. S.*

"Tannic Acid, 1 *ounce* (Imperial) or 20 grammes; Glycerin, sufficient to produce 5 *fl. ounces* (Imp. meas.) or 100 cubic centimetres. Triturate the Tannic Acid with the Glycerin until solution is effected." *Br.*

The U. S. preparation is a 20 per cent. solution by weight; the strength of the British preparation is somewhat weaker, being a 20 per cent. solution by measure. H. F. Meier found that the greenish scum usually seen on the surface of this preparation is chlorophyll from the tannin.

This preparation may be used, both internally and externally, for most of the purposes to

* *Glyceritum Picis Liquidæ.* U. S. 1870. *Glycerite of Tar.* "Take of Tar *a troyounce;* Carbonate of Magnesium, in powder, *two troyounces;* Glycerin *four fluidounces;* Alcohol *two fluidounces;* Water *ten fluidounces.* Having mixed the Glycerin, Alcohol, and Water, rub the Tar in a mortar, first with the Carbonate of Magnesium, and then with six fluidounces of the mixed liquids gradually added, and strain with expression. Rub the residue in like manner with half the remaining liquid, and strain as before. Repeat the process again with the remaining liquid. Put the residue into a percolator, add gradually the expressed liquids previously mixed, and afterwards a sufficient quantity of water to make the liquid which passes measure a pint." *U. S.*

This is a very excellent preparation of tar, which may be used either externally or internally. The formula is essentially the same as that proposed by Mr. J. B. Moore, although employing one-third less of the magnesium salt (*A. J. P.,* 1869, p. 115). As first made it is of a reddish-brown color; after a time it is apt to deposit a dark sediment, which should be separated by filtration. An ounce of it represents half a fluidrachm of tar. The dose is from a drachm to a half-ounce (3·75–15 C.c.).

which tannic acid is applied. On the whole, it is the most useful preparation of tannic acid for external use; as circumstances require it the official strength may be altered by directions of the physician; a very concentrated solution, two parts of glycerin to one of tannin, may be made by the aid of a moderate heat. This applied daily to nipples, during the later months of pregnancy, will usually prevent the occurrence of *sore nipples* during suckling. The dose is from ten to forty minims (0·6–2·5 C.c.). (See *Acidum Tannicum*, p. 98.)

GLYCERINUM ALUMINIS. Br. Glycerin of Alum.

(GLĬÇ-Ē-RĪ'NŬM Ą-LŪ'MĮ-NĬS.)

"Alum, in powder, 1 *ounce* (Imperial) or 20 grammes; Distilled Water, 3 *fl. drachms* (Imp. meas.) or 7·5 cubic centimetres; Glycerin, sufficient to produce 6 *fl. ounces* (Imp. meas.) or 120 cubic centimetres. Triturate until solution is effected, warming slightly if necessary; set aside; pour off the clear liquid from any deposited matter that may be present." *Br.*

This has the astringency of the glycerite of tannin without the tendency to soil the linen or blacken in contact with iron, but is much more irritating.

GLYCERITUM AMYLI. U. S. (Br.) Glycerite of Starch.

(GLĬÇ-Ē-RĪ'TŬM ĂM'Į-LĪ.)

Glycerinum Amyli, *Br.*, Glycerin of Starch; Unguentum Glycerini, *P. G.;* Glycamyl, Plasma glycéré d'Amidon, Glycérat simple (d'Amidon), *Fr.;* Stärke-Glycerit, *G.*

"Starch, *ten grammes* [or 154 grains]; Water, *ten cubic centimeters* [or 162 minims]; Glycerin, *eighty grammes* [or 2 ounces av., 360 grains]. To the Starch, contained in a porcelain capsule, add the Water and Glycerin, and stir until a homogeneous mixture is produced. Then apply a heat gradually raised to 140° C. (284° F.), and not exceeding 144° C. (291·2° F.), stirring constantly until a translucent jelly is formed. Transfer the product to suitable vessels, provided with well-fitting covers." *U. S.*

"Starch, 1 *ounce* (Imperial) or 20 grammes; Glycerin, 6½ *fl. ounces* (Imp. meas.) or 130 cubic centimetres; Distilled Water, 1½ *fl. ounces* (Imp. meas.) or 30 cubic centimetres. Mix; heat them together, stirring constantly, until a translucent jelly is formed." *Br.*

Of these preparations it is only necessary to say that, with the exception of an inconsiderable difference in the proportions, they are the same as that brought into notice in 1858 by Mr. G. F. Schacht under the name of *plasma*, as a substitute for ointments, the emollient and demulcent properties of which they possess, without their inconvenience, whether used simply, or as a vehicle for other substances to be employed locally. Mr. Schacht prepares plasma by mixing 70 grains of starch in powder, and a fluidounce of glycerin, heating to 240° F. until the union is effected, and stirring constantly. The stirring should be continued moderately, during the cooling, to secure a proper consistence. As the plasma is liable to absorb moisture, it should be kept in well-closed vessels. (*P. J. Tr.*, Oct. 1866, 210.) J. H. Pearson (*P. J. Tr.*, 1897, 201) recommends the addition of one grain of powdered tragacanth to the ounce of finished product, to prevent the separation of the glycerin and water from the mass, on standing.

GLYCERINUM BORACIS. Br. Glycerin of Borax.

(GLĬÇ-Ē-RĪ'NŬM BǪ-RĀ'CĬS.)

Glycérole de Borax, *Fr.;* Borax-Glycerol, *G.*

"Borax, 1 *ounce* (Imperial) or 20 grammes; Glycerin, 6 *fl. ounces* (Imp. meas.) or 120 cubic centimetres. Triturate the Borax with the Glycerin until solution is effected." *Br.*

The *Glyceritum Sodii Boratis* of U. S. P. 1870 was of the strength of *one troyounce* to *four fluidounces*. Otherwise it did not differ from the British preparation.

The demulcent properties and sweet taste of this preparation render it a useful and convenient method of applying borax to the infantile *thrush* and other forms of sore mouth in children. It has been highly commended in *erysipelas* by Prof. D. M. Salazar, of Madrid. The part should be freely painted with it and then covered with raw cotton. (*N. Y. Med. Record*, viii. 311.)

GLYCERITUM BOROGLYCERINI. U. S. (Br.) Glycerite of Boroglycerin.

[Glycerite of Glyceryl Borate. Solution of Boroglyceride.]

(GLĬÇ-Ē-RĪ'TŬM BŌ-RǪ-GLĬÇ-Ē-RĪ'NĪ.)

Glycerinum Acidi Borici, *Br.*, Glycerin of Boric Acid.

"Boric Acid, in fine powder, *three hundred and ten grammes* [or 10 ounces av., 409 grains]; Glycerin, *a sufficient quantity*, To make *one thousand grammes* [or 35 ounces av., 120 grains].

Heat *four hundred and sixty grammes* [or 16 ounces av., 99 grains] of Glycerin, in a tared porcelain capsule, to a temperature not exceeding 150° C. (302° F.), and add the Boric Acid in portions, constantly stirring. When all is added and dissolved, continue the heat at the same temperature, frequently stirring, and breaking up the film which forms on the surface. When the mixture has been reduced to the weight of *five hundred grammes* [or 17 ounces av., 278 grains], add to it *five hundred grammes* [or 17 ounces av., 278 grains] of Glycerin, mix thoroughly, and transfer it to suitable vessels." *U. S.*

"Boric Acid, in fine powder, 6 *ounces* (Imperial) or 300 grammes; Glycerin, *a sufficient quantity*. Heat *nine ounces* (Imp.) or four hundred and fifty grammes of Glycerin, in a weighed porcelain dish, to a temperature not exceeding 302° F. (150° C.), and add the Boric Acid in portions, constantly stirring. When all is dissolved maintain the temperature of the liquid, frequently stirring and breaking up the film which forms on the surface, until the mixture has been reduced to the weight of *ten ounces* [Imp.] or five hundred grammes; then add *ten ounces* (Imp.) or five hundred grammes of Glycerin; mix thoroughly. The product should weigh *twenty ounces* (Imp.) or one thousand grammes." *Br.*

This solution was introduced into the U. S. P. 1890 from the National Formulary. It is a thick, sweet, viscid, colorless liquid, and has the advantage of offering the antiseptic properties of boric acid in a very soluble form. It may be made more rapidly than by the above process if one ounce av. of boroglyceride be dissolved in one ounce av. of glycerin with the aid of a gentle heat. (See *Boroglyceridum*, PART II.)

GLYCERITUM HYDRASTIS. U. S. Glycerite of Hydrastis.

(GLĬÇ-Ē-RĪ'TŬM HĪ-DRĂS'TĬS.)

"Hydrastis, in No. 60 powder, *one thousand grammes* [or 35 ounces av., 120 grains]; Glycerin, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Alcohol, Water, each, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 390 minims]. Moisten the Hydrastis with *three hundred and fifty cubic centimeters* [or 11 fluidounces, 401 minims] of Alcohol, and pack it firmly in a cylindrical percolator; then add enough Alcohol to saturate the powder and leave a stratum above it. When the liquid begins to drop from the percolator, close the lower orifice, and, having closely covered the percolator, macerate for forty-eight hours. Then allow the percolation to proceed, gradually adding Alcohol until the Hydrastis is practically exhausted. To the percolate add *two hundred and fifty cubic centimeters* [or 8 fluidounces, 218 minims] of Water, and then drive off the Alcohol by evaporation or distillation. After the Alcohol is driven off, add enough Water to the residue to make it measure *five hundred cubic centimeters* [or 16 fluidounces, 435 minims], and set it aside for twenty-four hours. Then filter, pass enough Water through the filter to make the filtrate measure *five hundred cubic centimeters* [or 16 fluidounces, 435 minims], add the Glycerin, and mix thoroughly]." *U. S.*

This is a new official preparation which has been transferred to the U. S. P. 1890 from the National Formulary. It is intended to take the place of the various preparations which are in vogue and which go under the names of *Fluid Hydrastis*, *Colorless Hydrastis*, etc. F. A. Sieker found that glycerite of hydrastis as made by the U. S. process varies greatly in strength. (See *Proc. A. P. A.*, 1893, 691; also *Pharm. Rund.*, 1895, 236, and *Proc. A. P. A.*, 1894, 668.) Its medical properties are those of Hydrastis. Dose, from one-half to one fluidrachm (1·87–3·75 C.c.).

GLYCERINUM PEPSINI. Br. Glycerin of Pepsin.

(GLĬÇ-Ē-RĪ'NŬM PĔP-SĪ'NĪ.)

"Pepsin, 800 *grains* (Imperial) or 80 grammes; Hydrochloric Acid, 110 *minims* (Imp. meas.) or 10 cubic centimetres; Glycerin, 12 *fl. ounces* (Imp. meas.) or 525 cubic centimetres; Distilled Water, *a sufficient quantity*. Mix the Hydrochloric Acid, Glycerin, and *six fluid ounces* (Imp. meas.) or two hundred and sixty cubic centimetres of the Distilled Water; then add the Pepsin; after one week, pour off the clear liquid, or filter; add sufficient Distilled Water to produce *one pint* (Imp. meas.) or eight hundred and seventy-five cubic centimetres. 1 fluid drachm of this preparation represents 5 grains of Pepsin." *Br.*

This preparation is apparently identical with the glycerite of pepsin of the National Formulary; but the pepsin of the British Pharmacopœia is supposed to be five times as strong as that of the N. F. (See *Glyceritum Pepsini*, N. F., PART II.) The dose is one fluidrachm, equivalent to five grains of pepsin.

GLYCERINUM PLUMBI SUBACETATIS. Br. Glycerin of Subacetate of Lead.

(GLĬÇ-Ē-RĪ'NŬM PLŬM'BĪ SŬB-ĂÇ-Ē-TĀ'TĬS.)

"Lead Acetate, 5 *ounces* (Imperial) or 100 grammes; Lead Oxide, in powder, 3½ *ounces* (Imp.) or 70 grammes; Glycerin, 1 *pint* (Imp. meas.) or 400 cubic centimetres; Distilled Water, 12 *fl. ounces* (Imp. meas.) or 240 cubic centimetres. Mix; boil for a quarter of an hour; filter; evaporate at a temperature not exceeding 222° F. (105·5° C.) until the product weighs *thirty-two and three-quarters ounces* (Imp.) or six hundred and fifty-five grammes, and has a specific gravity of 1·48." *Br.*

This glycerite originated with Dr. Balmanno Squire, of London, but the process made official is that recommended by Dr. R. W. Parker. (See *A. J. P.*, 1886, 296.) It is a powerful sedative astringent, and may be employed as a local application in external inflammations.

GLYCERINUM TRAGACANTHÆ. Br. Glycerin of Tragacanth.

(GLĬÇ-Ē-RĪ'NŬM TRĂG-Ą-CĂN'THÆ.)

"Tragacanth, in powder, ½ *ounce* (Imperial) or 10 grammes; Glycerin, 1½ *fl. ounces* (Imp. meas.) or 30 cubic centimetres; Distilled Water, ½ *fl. ounce* (Imp. meas.) or 10 cubic centimetres. Mix the Glycerin with the Tragacanth; add the Distilled Water; triturate until a homogeneous paste is produced." *Br.*

This new official preparation has been introduced into the British Pharmacopœia mainly to serve as an excipient for pills.

GLYCERITUM VITELLI. U. S. Glycerite of Yolk of Egg. [Glyconin.]

(GLĬÇ-Ē-RĪ'TŬM VĮ-TĔL'LĪ.)

"Fresh Yolk of Egg, *forty-five grammes* [or 1 ounce av., 257 grains]; Glycerin, *fifty-five grammes* [or 1 ounce av., 411 grains], To make *one hundred grammes* [or 3 ounces av., 231 grains]. Rub the Yolk of Egg, in a mortar, with the Glycerin, gradually added, until they are thoroughly mixed. Then transfer the mixture to a bottle." *U. S.*

Under the name of *Glyconin* there has been employed in France for many years, both for medical purposes and for those of the toilet, an emulsion made of glycerin and the yolk of egg. When these two substances are rubbed together, they unite to form a very intimate mixture, which does not separate. It has the consistence of honey, and forms an opaque emulsion with water. It may be preserved almost indefinitely. The usual proportions of the ingredients are four parts of the yolk of egg and five parts of pure glycerin. It has been repeatedly recommended as a basis for cod-liver oil and other emulsions.* (See also papers by Mr. Close in *Proc. A. P. A.*, 1884 and 1886.) It is itself not medicinal.

GLYCYRRHIZA. U. S. (Br.) Glycyrrhiza. [Liquorice Root.]

(GLĬÇ-ĮR-RHĪ'ZĄ.)

Glycyrrhizæ Radix, *Br.;* Radix Liquiritiæ Glabræ, *P. G.;* Radix Glycyrrhizæ Hispanicæ; Spanish Licorice Root; Réglisse, Bois doux, Racine douce, Bois de Réglisse, *Fr.;* Spanisches Süssholz, Spanische Süssholzwurzel, Süssholzwurzel, *G.;* Liquirizia, *It.;* Regaliza, *Sp.*

"The root of Glycyrrhiza glabra, Linné, and of the variety glandulifera (Waldstein et Kittaibel), Regel et Herder (nat. ord. Leguminosæ)." *U. S.* "The peeled root and peeled subterranean stem of Glycyrrhiza glabra, Linn., and other species." *Br.*

Gen. Ch. Calyx bilabiate; upper lip three-cleft, lower undivided. *Legume* ovate compressed. *Willd.*

Glycyrrhiza glabra. Willd. *Sp. Plant.* iii. 1144; Woodv. *Med. Bot.* p. 420, t. 152; Carson, *Illust. of Med. Bot.* i. 38, pl. 32. The liquorice plant has a perennial root, which is round, succulent, tough, and pliable, furnished with sparse fibres, rapid in its growth, and in a sandy soil penetrates deeply into the ground. The stems are herbaceous, erect, and usually four or five feet in height, have few branches, and are garnished with alternate, pinnate leaves, consisting of several pairs of ovate, blunt, petiolate leaflets, with a single leaflet at the end, of a pale-green color, and clammy on their under surface. The flowers are violet or purple, formed

* *Glyconin Emulsion of Cod-Liver Oil.* The formula proposed by Mr. Close, and at one time largely used by Drs. Andrews, Beard, and others, is as follows. Cod-Liver Oil 4 fluidounces, Glyconin 9 fluidrachms, Aromatic Spirit of Ammonia 1 fluidrachm, Sherry Wine 2 fluidounces, Diluted Phosphoric Acid 4 fluidrachms, Essence of Bitter Almond (made by dissolving 1 fluidrachm of the volatile oil in half a pint of alcohol) 2 fluidrachms. The cod-liver oil is to be added *very slowly* to the glyconin with brisk stirring, and the other ingredients added in the order named.

like those of the pea, and arranged in axillary spikes supported on long peduncles. The calyx is tubular and persistent. The fruit is a compressed, smooth, acute, one-celled legume, containing from one to six small kidney-shaped seeds. There are two very distinct varieties of the plant yielding the root: the typical form, which is smooth throughout, and the variety, *G. glandulifera*, W. K., in which the stem, leaves, and pods are more or less roughly glandular or pubescent.

The habitat of the plant is wide-spread, extending from the shores of the Mediterranean to Siberia as far north as latitude 55°, and southward through Asia Minor and Persia to Farther India. The liquorice plant is cultivated in England,* the north of France, and Germany. It is also largely produced in the north of Spain, where it is an important article of commerce, and in Asia along the banks of the Tigris and Euphrates. It is probable that a portion of the root from Italy and Sicily is the product of *G. echinata*, which grows wild in Apulia. This species is also abundant in the south of Russia, where, according to Hayne, sufficient extract is prepared from it to supply the whole Russian empire. Large quantities of liquorice root are now imported for the purpose of making the extract, the imports for 1895 having been 83,281,275 lbs., valued at $1,404,563; for 1896, 87,123,461 lbs., valued at $1,401,748; and for 1897, 62,370,337 lbs., valued at $1,022,650.

A species of Glycyrrhiza, *G. lepidota*, grows abundantly about St. Louis, in the State of Missouri, and flourishes along the banks of the Missouri River to its source. It is probably the same as the liquorice plant mentioned by Mackenzie as growing on the northern coast of this continent. Mr. Nuttall states that its root possesses in no inconsiderable degree the taste of liquorice, and M. L. McCullough found it to contain 6·39 per cent. of crude glycyrrhizin, in contrast with 7·18 per cent. in the official species. (*A. J. P.*, 1890.)

Properties. The liquorice root of commerce is in long pieces, varying in thickness from a few lines to two inches, fibrous when not peeled, externally grayish brown and longitudinally wrinkled by desiccation, often warty, internally yellowish, pliable, tough, without smell, and of a sweet mucilaginous taste, mingled with a slight degree of acrimony. "Fracture coarsely fibrous; bark rather thick; wood porous, but dense, in narrow wedges; medullary rays linear; taste sweet, somewhat acrid. The underground stem, which is often present, has the same appearance, but contains a thin pith. The drug derived from the variety *glandulifera* (so-called Russian Liquorice) consists usually of roots or root-branches, 1 to 4 Cm. thick, 15 to 30 Cm. long, frequently deprived of the corky layer, the wood rather soft, and usually more or less cleft." *U. S.*† Formerly commerce was chiefly supplied with liquorice root by Italy and Spain, but the amount coming from these sources is at present probably not more than 10 per cent. of the whole, the greater portion coming from Southern Russia, a large amount from Anatolia and Syria, and a little from Turkey and Persia. The Spanish variety has been most esteemed, but, according to H. N. Rittenhouse, the peeled Russian liquorice is richer in glycyrrhizin and extractives than is any other variety, and is in fact the most valuable. Russian liquorice is usually very large, quite sweet, but at the same time rather more bitter and acrid than is the Spanish variety. Liquorice root is often worm-eaten and more or less decayed; such root should be rejected, as should also the small fibrous roots often shipped from Spain. The best pieces are large, bright yellow internally, and have the layers and the bark distinct. The bark is chiefly liber, consisting of parenchymatous tissue with bast-cells (which are stained yellow by iodine), and arranged so as to make ordinary liber bundles, and also a sort of net-work. A character said by Prof. Rothrock (*A. J. P.*, 1884) to be diagnostic is the occurrence in the wood and parenchyma of bundles composed of numerous bast-cells, surrounded by a sheath of large cells containing crystals of calcium oxalate. In the Russian root the parenchymatous wood-cells are larger than in the Spanish. The powder is of a grayish-yellow color, when the root is pulverized without being deprived of its epidermis; of a pale sulphur-yellow, when the epidermis has been removed. Robiquet found the following ingredients in liquorice root: 1, a peculiar transparent yellow substance, called *glycyrrhizin*, of a sweet taste, scarcely soluble in cold water, very soluble in boiling water, with which it gelatinizes on cooling, thrown down from its aqueous solution by acids, readily soluble in cold alcohol, insusceptible of the vinous fermentation, yielding no oxalic acid by the action of the nitric, and therefore wholly distinct

* Most of the liquorice root of commerce appears to be the product of wild plants, but it has been successfully cultivated in England (*A. J. P.*, 1874, 473) and in Syria (*P. J. Tr.* xvi. 647). Although the attempts to produce it in the United States have hitherto met with no great success, we can see no reason why in some of the lowlands of the Southeastern States it should not flourish. An interesting report upon the production of liquorice root in Spain was made by Mr. H. C. Marsten, United States consul, and may be found abstracted in *New Remedies*, Jan. 1882.

† For the anatomical structure of the root, see *Arch. d. Pharm.*, June, 1888.

from sugar; 2, a crystallizable principle named *agedoïte* by Robiquet, but subsequently proved to be identical with *asparagin;* 3, starch; 4, albumen; 5, a brown acrid resin; 6, a brown nitrogenous extractive matter; 7, lignin; 8, salts of lime and magnesia, with phosphoric, sulphuric, and malic acids. Flückiger states that a small amount of tannin is also always contained in the root, or rather its bark. The chief constituent, *glycyrrhizin*, Gorup-Besanez (*Ann. Ch. und Pharm.*, 118) considered to be a glucoside, having the composition $C_{24}H_{36}O_9$. On boiling with dilute acids it breaks up into *glycyrrhetin* and an uncrystallizable sugar capable of fermentation. Roussin (*Journ. de Pharm. et de Chim.*, July, 1875) found that the sweet taste of the root was not owing to the free glucoside, but to its compound with ammonia. Habermann (*Ann. Ch. und Pharm.*, 197) found that glycyrrhizin-ammonia was the acid ammonium salt of glycyrrhizic acid, a nitrogenous acid, and gave the formula $C_{44}H_{62}NO_{18}.NH_4$ for it. (See *Glycyrrhizinum Ammoniatum.*) He succeeded in extracting from the commercial "ammoniacal glycyrrhizin" *glycyrrhizic acid*, which may be considered to be the active constituent of liquorice. It was obtained by dissolving the crude glycyrrhizin in glacial acetic acid at a boiling temperature, rapidly filtering, again treating the crystalline parts of the filtrate in the same manner, and finally purifying by repeated crystallizations from 90-per-cent. alcohol. Its properties are peculiar, and account to a great extent for the singular behavior of liquid liquorice preparations. With water, in which the substance is but little soluble at ordinary temperature, it forms a transparent, faintly yellow jelly. On mixing 1 Gm. of the body with 100 C.c. of water, the mixture after a few hours becomes so jelly-like that the open vessel may be inverted without losing any substance. It is insoluble in ether, but slightly soluble in absolute alcohol (even boiling), more so in alcohol of 90 per cent., and especially so when hot. Its solubility increases with the decrease of the percentage of alcohol. The apparent glucosidal character of glycyrrhizic acid Habermann explains by the fact that it breaks up on boiling with dilute sulphuric acid into *glycyrrhetin* and *parasaccharic acid*, according to the reaction $C_{44}H_{63}NO_{18} + 2H_2O = C_{32}H_{47}NO_4 + 2C_6H_{10}O_8$. (*Ann. d. Chem.*, 197; *N. R.*, Sept. 1879.) By fusing glycyrrhizin with caustic potash, Weselsky and Benedikt (*Deutsch. Chem. Ges.*, 1876) obtained *paraoxybenzoic acid.*

Medical Properties and Uses. Liquorice root is an excellent demulcent, well adapted to pulmonic catarrhs, and even to irritations of the mucous membrane of the bowels and urinary passages; but it is chiefly used for the purpose of concealing the taste or of covering the acrimony of various drugs, such as ammonium chloride or senega. A decoction may be prepared by boiling an ounce of the bruised root, for a few minutes, in a pint of water, but at present the extract is almost universally preferred. The powder is used in the preparation of pills, either to give due consistence or to cover their surface and prevent them from cohering.

For formulas of Aromatic Elixir and Syrup of Liquorice, see PART II., *National Formulary.*

GLYCYRRHIZINUM AMMONIATUM. U. S. Ammoniated Glycyrrhizin.

(GLĬÇ-ŸR-RHĪ-ZĪ'NŬM ĄM-MŌ-NĪ-Ā'TŬM.)

"Glycyrrhiza, in No. 20 powder, *five hundred grammes* [or 17 ounces av., 278 grains]; Water, Ammonia Water, Sulphuric Acid, each, *a sufficient quantity.* Mix *four hundred and seventy-five cubic centimeters* [or 16 fluidounces, 30 minims] of Water with *twenty-five cubic centimeters* [or 405 minims] of Ammonia Water, and, having moistened the powder with the mixture, macerate for twenty-four hours. Then pack it moderately in a conical glass percolator, and gradually pour Water upon it until *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of percolate are obtained. Add Sulphuric Acid slowly to the percolate, with constant stirring, so long as a precipitate is produced. Collect this on a strainer, wash it with cold Water until the washings no longer have an acid reaction, redissolve it in Water with the aid of Ammonia Water, filter, if necessary, and again add Sulphuric Acid so long as a precipitate is produced. Collect this, wash it, dissolve it in a sufficient quantity of Ammonia Water previously diluted with an equal volume of Water, and spread the clear solution upon plates of glass, so that, when dry, the product may be obtained in scales." *U. S.*

This is a preparation whose introduction is a result of the very important researches of Z. Roussin, communicated to the Société de Pharmacie of Paris, June 2, 1875. This investigator noticed that *glycyrrhizin*, the sweet principle of liquorice root, was insipid when compared with the root itself, and suspected that it existed in a modified form in the root. Experiment showed that alkalies developed the sweet taste, and he ultimately proved that the alkali with which it was combined in the root was ammonia, and that glycyrrhizin played the part of an acid. He

named the compound *ammonium glycyrrhizate*, and called attention to the fact that liquorice root which had lost a portion of its sweetness through fermentation and the development of acetic acid and precipitation of insoluble glycyrrhizin could be restored to its former sweetness if allowed to remain a sufficient length of time in an ammoniacal atmosphere. The official process for ammoniated glycyrrhizin is closely modelled after Roussin's, with the exception of the substitution of percolation by a slightly ammoniated menstruum for maceration and expression with cold water. Roussin purified his product by redissolving it in alcohol and precipitating with ether; this is deemed unnecessary for a preparation which is intended to be useful without being expensive. (See *Proc. A. P. A.*, 1876, p. 544.) Connerade has proposed some modification of Roussin's method; his process is as follows. "Macerate ground liquorice root with one and a half parts by weight of water, strain, wash the residue with a very small quantity of water, heat the mixed liquids to boiling to coagulate albumen, strain again, and then add diluted sulphuric acid (1 in 10), as long as a precipitate is produced. Let this settle, decant the liquid, and dissolve the precipitate in solution of ammonia, diluted with nine parts of water. Filter the latter and evaporate it to dryness. The compound then remains as a brown, friable varnish, unaltered by air, of a pure, sweet taste, easily soluble in cold water, and imparting to the latter, even when diluted to 1 in 1000 parts, an amber color. The yield is about 10 per cent. of the weight of the root." (*N. R.*, March, 1881.)

Properties. The following is the description given in the U. S. Pharmacopœia: "Dark brown or brownish-red scales, without odor, and having a very sweet taste. Readily soluble in water and in alcohol. The aqueous solution, when heated with potassium or sodium hydrate test-solution, evolves ammoniacal vapors. If the aqueous solution be supersaturated with an acid, there will be produced a precipitate (glycyrrhizin) which, when dissolved in hot water, forms a jelly on cooling. This substance, after being washed with diluted alcohol, and dried, appears as an amorphous, yellow powder, having a strong, bitter-sweet taste, and an acid reaction. Upon incineration, Ammoniated Glycyrrhizin should not leave more than a trace of ash."

Medical Properties and Uses. This substance appears to possess the medical properties of liquorice, and may be used as an elegant substitute for it in mixtures which are neither acid nor alkaline. The dose of it is from five to fifteen grains (0·32–0·97 Gm.).

GOSSYPII RADICIS CORTEX. U. S. Cotton Root Bark.

(GOS-SĬP'I-Ī RĂ-DĪ'CĬS CŌR'TĔX.)

"The bark of the root of Gossypium herbaceum, Linné, and of other species of Gossypium (nat. ord. Malvaceæ)." *U. S.*

Cottonroot Bark; Ecorce de la Racine de Cotonnier, *Fr.*; Baumwollen-Wurzelrinde, *G.*

In consequence of changes produced in the plants of this genus by cultivation, botanists have found great difficulty in determining which are distinct species and which are merely varieties. De Candolle describes thirteen species in his Prodromus, and mentions six others, but considers them all uncertain. Royle describes eight and admits others. Schwartz thinks that they may all be referred to one original species. Engler and Prantl recognize six species, three of these being cultivated. The plants inhabit different parts of tropical Asia and Africa, and many of them are cultivated for their cotton in climates adapted to their growth. The species from which most of the cotton of commerce has been thought to be obtained is the one specially indicated by the U. S. Pharmacopœia. According to Dr. Royle, it is the India cotton which is produced by *G. herbaceum*, while *G. barbadense* furnishes all the cotton of North America, and *G. peruvianum* that produced in Brazil, Peru, and other parts of South America. (See *A. J. P.*, 1858, 339.) Dr. A. W. Chapman, however, in his *Flora of the Southern United States* (New York, 1860, 58), states that the numerous varieties of the cotton-plant are now referred to two species, the *long-staple*, or *sea-island*, to *G. album* (Haw.), and the *short-staple*, or *upland*, to *G. nigrum* (Haw.).

Gossypium herbaceum. Linn. *Sp. Plant.* 975; De Cand. *Prodrom.* i. 456. This is a biennial or triennial plant, with a branching stem from two to six feet high, and palmate hoary leaves, the lobes of which are somewhat lanceolate and acute. The flowers are pretty, with yellow petals, having a purple spot near the claw. The leaves of the involucel or outer calyx are serrate. The capsule opens when ripe, and displays a loose white tuft of long slender filaments, which surround the seeds and adhere firmly to the outer coating. The plant is a native of Asia, but is cultivated in most tropical countries. It requires a certain duration of warm weather to perfect its seeds, and, in the United States, does not mature north of Virginia.

The herbaceous part of the plant contains much mucilage, and has been used as a demulcent.

The seeds yield by expression a fixed oil of the drying kind, which is employed for making soap and for other purposes. (See *Oleum Gossypii.*) The bark of the root has been supposed to possess medical virtues, and is recognized by the U. S. Pharmacopœia. Another official portion, and that for which the plant is cultivated, is the filamentous substance surrounding the seeds. This when separated constitutes the cotton of commerce. Cotton seeds have been employed in our Southern States with great asserted success in the treatment of intermittents, but are at present seldom, if ever, used. (For details, see U. S. D., 16th ed.)

Properties. Cotton Root Bark is officially described as "in thin, flexible bands or quilled pieces; outer surface brownish-yellow, with slight, longitudinal ridges or meshes, small, black, circular dots, or short, transverse lines, and dull, brownish-orange patches, from the abrasion of the thin cork; inner surface whitish, of a silky lustre, finely striate; bast-fibres long, tough, and separable into papery layers; inodorous; taste very slightly acrid and faintly astringent." *U. S.* Prof. E. S. Wayne, of Cincinnati, found in it a peculiar acid resin, colorless and soluble in water, when pure, but absorbing oxygen on exposure, and then becoming red and insoluble in water. It is deposited by the fluid extract on standing. He suggests that this may be the active principle of the root; but the fact has not been determined. (*A. J. P.*, 1872.) William C. Staehle (*A. J. P.*, 1875) made an examination of this resin, and obtained results somewhat different from those of Prof. Wayne. Staehle's percolate was of a dark reddish-brown color, whilst Wayne's was pale amber. This is accounted for, however, by the presence of a principle which is colorless in the fresh bark, but of a dark red in bark which has been exposed to air and light. W. A. Taylor noticed that the change in color from pale amber to dark red took place in an alcoholic tincture. (*A. J. P.*, 1876.) Staehle found the resin soluble in 14 parts of alcohol, 15 parts of chloroform, 23 parts of ether, and 122 parts of benzene.

Medical Properties. It has been employed by Dr. Bouchelle, of Mississippi, who believes it to be an excellent emmenagogue, and not inferior to ergot in promoting uterine contraction. He states that it was habitually resorted to by the slaves of the South for producing abortion. To assist labor, he employs a decoction made by boiling four ounces of the inner bark of the root in a quart of water to a pint, and gives a wineglassful (60 C.c.) every twenty or thirty minutes. (*West. Journ. of Med. and Surg.*, Aug. 1840.) These opinions of Dr. Bouchelle have been confirmed by various Southern medical practitioners, and Dr. H. I. Garrigues asserts that the cotton root has great powers in arresting hemorrhage and ameliorating the other symptoms of *uterine fibroids;* but, for some reason, the drug failed to come into general use. Dr. Bellany, of Columbus, Georgia, says that the root should be gathered as late as possible in the fall before frost. The official fluid extract may be used in doses of half a fluidrachm to one fluidrachm (1·9 to 3·75 C.c.), repeated at short intervals if necessary.

GOSSYPIUM PURIFICATUM. U. S. (Br.) Purified Cotton.

[Absorbent Cotton.]

(GŌS-SĬP'Ĭ-ŬM PŪ-RĬ-FĬ-CĀ'TŬM.)

"The hairs of the seed of Gossypium herbaceum, Linné, and of other species of Gossypium (nat. ord. Malvaceæ), freed from adhering impurities and deprived of fatty matter." *U. S.* "The hairs of the seed of Gossypium barbadense, Linn., and of other species of Gossypium, freed from fatty matter." *Br.*

Gossypium, *Br.*, Cotton Wool; Bonelyax, Lana (Lanugo, s. Pili) Gossypii; Coton, *Fr.;* Baumwolle, *G.;* Cotone, *It.;* Algodon, *Sp.*

Cotton consists of "white, soft, fine filaments, under the microscope appearing as flattened, hollow, and twisted bands, spirally striate and slightly thickened at the edges; inodorous, tasteless, insoluble in ordinary solvents; but soluble in copper ammonium sulphate solution." It is without smell or taste, soluble in strong alkaline solutions, and decomposed by the concentrated mineral acids. In chemical character it is related to but not identical with lignin, the latter being an alteration product and sometimes called oxycellulose. By nitric acid it is converted into that remarkable explosive substance denominated gun cotton, for an account of which see *Pyroxylinum* and *Collodium.* Official cotton is made by boiling the raw cotton in a diluted alkaline solution, a process sometimes known as "mercerizing," as practised on a large scale in the technical preparation of cotton fibre. A soap is formed through the union of the fatty matter with the alkali, and this is subsequently dissolved out by repeated washings. Mr. F. L. Slocum published in 1881 a process for preparing it. For details see the foot-note.* The U. S. P. tests are as follows: "Purified Cotton should be perfectly free from

* Take of the best quality of carded cotton batting any desired quantity, and boil it with a 5 per cent. solution of caustic potassa or soda for one-half hour, or until the cotton is entirely saturated with the solution, and the alkali

all visible impurities, and, on combustion, should not leave more than 0·8 per cent. of ash. When Purified Cotton, previously compressed in the hand, is thrown on the surface of cold water, it should readily absorb the latter and sink, and the water should not acquire either an acid or an alkaline reaction (evidence of proper purification)." The latter test proves the absence of fatty matter, for if even a small quantity be present the cotton will float in water. Repeated experiments have proved that cotton will take fire and burn spontaneously if impregnated with olive oil, linseed oil, or almost any other fixed oil, and allowed to stand. (*P. J. Tr.*, 1872, p. 225.) Cotton, analyzed by M. Schunck, was found, independently of cellulose $(C_6H_{10}O_5)_n$, of which it chiefly consists, to contain vegetable wax, a fatty acid, coloring matter, pectic acid, and a little of an albuminoid substance. (*Journ. de Pharm.*, Sept. 1868, 233.) For medical use it should be carded into thin sheets.* It is said that air passed through cotton loses the property of inducing fermentation, on account of the microscopic organisms being strained out of it; and this fact has been utilized in preserving infusions by placing them in bottles containing corks armed with tubes loosely filled with cotton, and drawing the infusion from a stop-cock near the bottom.

Medical Properties. The use of cotton as a filtering medium and in the preparation of medicated waters has already been alluded to. It is much used in surgery as a dressing for burns, scalds, blisters, and wounds, in order to prevent the access of pathogenetic germs.† Cotton batting is often employed to maintain a uniform temperature in parts affected with acute rheumatic inflammation.

GRANATUM. U. S. (Br.) Pomegranate.

(GRĀ-NĀ'TŬM.)

"The bark of the stem and root of Punica Granatum, Linné (nat. ord. Lythrarieæ)." *U. S.*
"The dried bark of the stem and root of Punica Granatum, Linn." *Br.*

Granati Cortex, *Br.*, Pomegranate Bark; Cortex Radicis Granati, *P. G.;* Ecorce de la Racine de Grenadier (de Balaustier), Ecorce de Granade, *Fr.;* Granatwurzelrinde, Granatäpfelschale, *G.;* Malicorio, Scorza del Melogranati, *It.;* Corteza de Granada, *Sp.*

Punica granatum. Willd. *Sp. Plant.* ii. 981; Woodv. *Med. Bot.* p. 531, t. 190; Carson, *Illust. of Med. Bot.* i. 45, pl. 38. The pomegranate is a small shrubby tree, attaining in favorable situations the height of twenty feet, with a very unequal trunk, and numerous branches which sometimes bear thorns. The leaves are opposite, entire, oblong or lance-shaped, pointed at each end, smooth, shining, of a bright-green color, and placed on short footstalks. The flowers are large, of a rich scarlet color, and stand at the end of the young branches. The petals are roundish and wrinkled, and are inserted into the upper part of the tube of the calyx, which is red, thick, and fleshy. The fruit is a globular berry, about the size of an orange, crowned with the calyx, covered with a reddish-yellow, thick, coriaceous rind, and divided internally into many cells, which contain an acidulous pulp, and numerous oblong, angular seeds.

This tree grows wild upon both shores of the Mediterranean, in Arabia, Persia, Bengal, China, and Japan, has been introduced into the East and West Indies, and is cultivated in all civilized countries where the climate is sufficiently warm to allow the fruit to ripen. In higher

has saponified all oily matter. Then wash thoroughly, to remove all soap, and nearly all alkali; press out the excess of water, and immerse in a 5 per cent. solution of chlorinated lime for 15 or 20 minutes; again wash, first with a little water, then dip in water acidulated with hydrochloric acid, and thoroughly wash with water; press out the excess of water, and again boil for 15 or 20 minutes in a 5 per cent. solution of caustic potassa or soda; now wash well, dipping in the acidulated water and washing thoroughly with pure water. Afterwards press out and dry quickly.

The amount of loss by this process is practically 10 per cent. A sample of 360 grs. lost, on boiling with alkali and bleaching, 15 grs., or 4·17 per cent., and 270 grs. of this bleached sample lost, on again boiling with an alkali, 14 grs., or 5·18 per cent., a total loss of 9·35 per cent. (*A. J. P.*, 1881, p. 53.)

* *Wood Wool.* Under this name Prof. Bruns has introduced finely grained, purified wood-fibre, such as is used in making paper. It may be medicated like cotton. (*N. R.*, 1883, p. 361.)

† Absorbent cotton has been medicated in various ways and come largely into use. (See *Iodized Cotton*, under *Iodum.*) *Picric Cotton* is prepared by dissolving 0·25 Gm. of picric acid in 25 Gm. of ether, or of 94 per cent. alcohol, and immersing in the solution 10 Gm. of clean cotton, and drying. *Salicylic Cotton* (5 per cent.) may be prepared by Prof. Bruns's process, by saturating 1 kilogramme of cotton with 4 liters of a solution of 50 Gm. of salicylic acid, and 20 Gm. of castor oil in 3·930 liters of alcohol. *Benzoic Cotton* is made in the same way, substituting benzoic for salicylic acid. (*A. J. P.*, Dec. 1878.) *Chlorinated Cotton.* Prof. Pavesi subjects cotton moistened with glycerin, and suspended at the top of a large wide-mouthed bottle, to the action of chlorine vapor, generated by adding sulphuric acid to chlorinated lime. (*N. R.*, July, 1880.) Mr. Joseph W. England communicates in *A. J. P.*, 1887, p. 173, practical formulas for preparing the following medicated cottons and gauzes: *Borated Cotton, Benzoated Cotton, Salicylated Cotton, Naphthalinated Cotton, Iodoformized Cotton, Carbolized Cotton, Sublimated Cotton, Carbolized Gauze, Sublimated Gauze, Absorbent Canton Flannel.* For methods of assay of medicated cottons, gauzes, etc., see *Proc. A. P. A.*, 1897, 457, 458, 459.

latitudes, where it does not bear fruit, it is raised in gardens and hot-houses for the beauty of its flowers, which become double and acquire increased splendor of coloring by cultivation. Doubts have been entertained as to its original country. The name of *Punicum malum*, applied by the ancients to its fruit, implies that it was abundant at an early age in the vicinity of Carthage. The fruit, for which the plant is cultivated, varies much in size and flavor. It is said to attain greater perfection in the West Indies than in its native country. The edible pulp is red, succulent, pleasantly acid, and sweetish. The flowers were recognized by the Dublin College, and the seeds are official in France.

Pomegranate bark. *e*, cork layer; *o*, middle bark; *v*, inner bark; *q*, medullary rays; *r*, sieve, parenchymatous tissue with calcium oxalate crystals. (After Berg.)

Rind of the Fruit. This is presented in commerce under the form of irregular fragments, hard, dry, brittle, of a yellowish or reddish-brown color externally, paler within, without smell, and of an astringent, slightly bitter taste. It contains a large proportion of tannin, and, in countries where the tree abounds, has been employed for tanning leather.

Flowers. The flowers, sometimes called *balaustines*, are inodorous, have a bitterish, astringent taste, and impart a violet-red color to the saliva. They contain tannic and gallic acids, and were used by the ancients in dyeing.

Bark of the Root. The roots of the pomegranate are hard, heavy, knotty, ligneous, and covered with a bark which is yellowish-gray or ash-gray on the outer surface, and yellow on the inner. As officially described, the bark is "in thin quills or fragments, from 5 to 10 Cm. long, and from 1 to 3 Mm. thick; outer surface yellowish-gray, somewhat warty, or longitudinally and reticulately ridged; the stem-bark often partly covered with blackish lichens; the thicker pieces of the root-bark more or less scaly externally; inner surface smooth, finely striate, grayish-yellow; fracture short, granular, greenish-yellow, indistinctly radiate; inodorous; taste astringent, very slightly bitter." *U. S.* "The transverse section exhibits numerous fine radial and tangential lines." *Br.* It has little or no smell, colors the saliva yellow when chewed, and leaves in the mouth an astringent taste without disagreeable bitterness. The infusion of the bark yields a deep-blue precipitate with salts of iron, and a yellowish-white precipitate with solution of gelatin. The inner surface of the bark, steeped in water and then rubbed on paper, produces a yellow stain, which by the contact of ferrous sulphate is rendered blue, and by that of nitric acid acquires a slight rose tint, which soon vanishes. These properties serve to distinguish this bark from those of the box root and barberry, with which it is said to be sometimes adulterated. When used, it should be separated from the ligneous portion of the root, as the latter is inert. The bark contains more than 22 per cent. of tannic acid, which Rembold (*Ann. der Ch. und Pharm.*, 143, 285) found to consist for the most part of a peculiar variety, *punico-tannic acid*, $C_{20}H_{16}O_{13}$; when boiled with dilute sulphuric acid it is resolved into *ellagic acid*, $C_{14}H_8O_8$, and sugar. Punico-tannic acid is accompanied by common tannic acid, yielding by means of sulphuric acid gallic acid, which appears sometimes to pre-exist in the bark. Henry Trimble, however (*A. J. P.*, 1897, 636), as the result of an ultimate analysis of the purified tannin and a study of its reactions, pronounced it to be identical with gallotannic acid. Pomegranate bark also yields a considerable quantity of *mannite*, which was formerly described under the names of *punicin* or *granatin*. The active power of the root, however, is due, according to Tanret (*Compt.-Rend.*, 86, 1270, and 87, 358), to an alkaloid *pelletierine*, $C_8H_{15}NO$, a dextrogyrate liquid boiling at 195° C., easily soluble in water, alcohol, and ether, and specially so in chloroform. It has strong basic properties, and precipitates many metallic salts: 1000 parts of dry bark yielded 4 parts of it.*

* The bark of the stem of the pomegranate is sold as root-bark: for microscopic diagnosis, see *P. J. Tr.*, 1873. As the anthelmintic activity of the barks of different portions of the plant is important, the analyses of Mr. Stoeder are of interest. His results are: stem and branch bark, in thin quills, 0·612 per cent.; average quills, 0·350 per cent.; thick quills, 0·498 per cent.; root-bark from south of Europe, in thick quills, 1·010 per cent.; shaved root-bark from Java, 1·326 per cent.; exfoliated bark from dry thick roots of unknown age, 1·240 per cent.; finely rasped wood from these roots, 0·218 per cent. According to the same authority (*Nederl. Tijd. Pharm.*, 1890), of the bark of three varieties of the wild pomegranate recognized and used by the natives of Java, the red-flowered, "merah," yielded 2·43 per cent.; the white-flowered, "poetih," yielded 3·75 per cent.; the black-flowered, "hitam," yielded 1·71 per cent.

In a later communication (*Compt.-Rend.*, 88, p. 716), Tanret announced that he had found three additional volatile bases in the bark, a liquid left-rotating one, a liquid optically inactive one, and a crystallizable inactive one, which latter has the formula $C_9H_{15}NO + 2H_2O$, fuses at 46° C., and boils at 246° C. His process for obtaining these alkaloids is as follows. A mixture of the salts of the alkaloids is prepared by mixing the powdered bark with a milk of lime, exhausting with water, shaking the resulting liquor with chloroform, and neutralizing the latter with dilute acid. A solution of the mixed alkaloids is thus obtained in which one or other of them predominates, according to the source of the bark. Two of the four alkaloids are displaced from their salts by sodium bicarbonate, and two are not. This solution is therefore treated with an excess of sodium bicarbonate and shaken with chloroform, and this in its turn is agitated with dilute sulphuric acid. The resulting solution contains the sulphates of two alkaloids, to which the names of "*methylpelletierine*," $C_9H_{17}NO$, and "*pseudopelletierine*," $C_9H_{15}NO$, have been given. Caustic potash is then added to the first liquor, and upon repeating the treatment with chloroform and acid there is obtained a solution of "pelletierine" and "*isopelletierine*" sulphates. (*P. J. Tr.*, 1880.) Carl J. Bender (*Pharm. Centralh.*, 1885, p. 6) found three bases in pomegranate bark, one crystallizable and two amorphous. He objects to the name pelletierine, and substitutes "*punicine*." Wm. F. Junkunz analyzed pomegranate bark, and believes that the alkaloid exists in the bark as a tannate. (*A. J. P.*, 1884.) The old idea that the bark loses activity when kept seems to be negatived by the analysis of De Vrij. (*P. J. Tr.*, xxi.)

Medical Properties and Uses. The rind of the pomegranate fruit was formerly recognized by the U. S. Pharmacopœia. It is astringent, and in the form of decoction is sometimes employed in *diarrhœa* and *colliquative sweats*, and, more frequently, as an injection in *leucorrhœa*, and as a gargle in *sore throat* in the earlier stages, or after the inflammatory action has in some measure subsided. The powdered rind has also been recommended in *intermittent fever*. The flowers have the same medical properties and are used for the same purposes. The bark of the root was used by the ancients as a vermifuge, and is recommended in the writings of Avicenna, but was unknown in modern practice till brought into notice by Dr. F. Buchanan, who learned its powers in India. The Mahometan physicians of Hindostan consider it a specific against *tænia*. One of these practitioners, having relieved an English gentleman in 1804, was induced to disclose his secret, which was then made public. The French writers prefer the product of the wild pomegranate, growing on the borders of the Mediterranean, to that of the plant cultivated in gardens for ornamental purposes. The bark may be administered in powder or decoction; but the latter form is usually preferred. The decoction is prepared by macerating two ounces of the bruised bark in two pints of water for twenty-four hours, and then boiling to a pint. Of this a wineglassful may be given every half-hour, hour, or two hours, until the whole is taken. It often nauseates and vomits, and usually purges. Portions of the worm often come away soon after the last dose. It is recommended to give a dose of castor oil and to diet the patient strictly on the day preceding the administration of the remedy, and, if it should not operate on the bowels, to follow it by castor oil, or an enema. If not successful on the first trial, it should be repeated daily for three or four days, until the worm is discharged. It appears to have been used by the negroes of San Domingo before its introduction into Europe.

The efficacy of pelletierine as a tænicide has been abundantly confirmed, and it appears to be established that the tannate is the most effective and the least dangerous form of the remedy, —probably because its insolubility prevents its rapid absorption and enables it to come in prolonged contact with the worm. The experiments of Dr. Dujardin-Beaumetz have shown that the pelletierine alkaloids act upon the higher animals like curare, causing paralysis of the motor nerves without affecting sensation or muscular contractility. The same authority asserts that hypodermic injections of six grains produce in man severe vertigo, muscular weakness, and great retinal congestion. Double vision has also been noted, and Galezowski has been led by it to prescribe pelletierine in paralysis of the third and sixth pairs of nerves: he affirms that he has succeeded in affording relief after the failure of potassium iodide and blisters. The proper dose of pelletierine tannate is variously given by authorities. It has been stated to be from one-half to three-quarters of a grain (0·03–0·05 Gm.) (*Bull. Thérap.*, xcvi., xcvii.), but others place it as high as eight grains (0·52 Gm.). Commercially, it occurs almost exclusively as a syrupy solution, put up, we believe, under the supervision of its discoverer, each bottle containing a single dose, it is stated, of about five grains. We have seen pronounced temporary general palsy produced in a female adult by this dose. The dose of pomegranate rind and flowers in powder is from twenty to thirty grains (1·3–1·95 Gm.). A decoction may be prepared in the

proportion of an ounce of the medicine to a pint of water, and given in the dose of a fluidounce (30 C.c.). The remedy should always be given after a twelve hours' fast, and be followed in two hours by a brisk cathartic. The seeds are demulcent.

GRINDELIA. U. S. Grindelia.

(GRĬN-DĒ'LĬ-Ą.)

"The leaves and flowering tops of Grindelia robusta, Nuttall, and of Grindelia squarrosa, Dunal (nat. ord. Compositæ)." *U. S.*

This genus inhabits the western side of both North and South America. Most if not all of the species produce a resinous exudation, especially from the flower-heads, and it is probable that medical properties are common to the genus.

G. robusta, Nuttall, is an herbaceous plant, from one to three feet high, very glabrous, with leaves varying from broadly spatulate or oblong to lanceolate, or the upper cordate and clasping, commonly obtuse, sharply more or less serrate; the scales of the involucre are produced into long circinate, squarrose, awn-like tips; the pappus of two to three, rarely five, nearly smooth, flattish awns; akenes mostly one- to three-toothed at the apex.

G. squarrosa, Dunal (1836) [Syn. *Donia squarrosa*, Pursh (1814), and *G. squarrosa* (Pursh) Dunal], is in general a less leafy and bushy plant than is *G. robusta*, but so closely resembles some varieties of the latter that, after a careful study of various published descriptions and of the specimens in the herbarium of the Philadelphia Academy of Natural Sciences, we are not satisfied of the specific distinctness. The character pointed out by Torrey and Gray, that in *robusta* the leaves are broader at the base than above, does not hold; for in a specimen in the herbarium of the Academy of Natural Sciences labelled in Nuttall's handwriting, and, therefore, probably the type of *G. robusta*, the leaves are not broader at the base; whilst in various specimens of *G. squarrosa* they are not narrowed at the base. The most constant distinctive characters in the specimens at hand are that *G. robusta* has a more leafy involucre and its leaves usually are more coarsely serrate; but Watson describes a variety of *G. robusta* in which the upper leaves are entire. There is no constant difference in the scales of the involucre. According to Joseph Beauvais (*A. J. P.*, Feb. 1889), the resin of the leaf of *G. robusta* is contained in epidermal glands, and also in rather large resin-ducts situated in an interior collenchymatous layer.

Properties. The official description of grindelia is as follows: "Leaves about 5 Cm. or less long, varying from broadly spatulate or oblong to lanceolate, sessile or clasping, obtuse, more or less sharply serrate, often spinosely toothed, or even laciniate-pinnatifid, pale green, smooth, finely dotted, thickish, brittle; heads many-flowered, subglobular or somewhat conical; the involucre hemispherical, about 10 Mm. broad, composed of numerous imbricated, squarrosely-tipped or spreading scales; ray-florets yellow, ligulate, pistillate; disk-florets yellow, tubular, perfect; pappus consisting of two or three awns of the length of the disk-florets; odor balsamic; taste pungently aromatic and bitter." *U. S.* (See also *Merck's Report*, 1898, 362.)

As it occurs in commerce, grindelia is in the form of the whole dried herb; the stems are about eighteen inches in length, light brownish, very frequently stripped of their leaves, but with some of the floral heads adherent. The brittle leaves are much broken, and with separated floral heads are mixed with the stem. The taste is warmish, peculiar, and very persistent. The specimens we have examined seemed to contain numerous floral heads, some according with those of the typical *G. robusta*, others without trace of involucral leaves. Some of the latter may have been removed, it is true, by accidents of carriage; but if *G. squarrosa* and *G. robusta* be distinct species, it would appear that they are indiscriminately collected. The activity of the drug probably resides in the resinous exudation. Dr. C. J. Rademaker obtained from it an oil, the odor of which closely resembled that of oil of turpentine, resin, and a crystalline body having an alkaline reaction. (*N. R.*, 1876, p. 205.) W. H. Clark and John L. Fischer (*A. J. P.*, 1888, p. 433) failed to verify all of Dr. Rademaker's results, but obtained an alkaline principle to which the name of *grindeline* was given. Dr. A. Schneegans (*A. J. P.*, 1892, 369) found in grindelia robusta saponin, which, he states, is composed of two glucosides; he also found indications of an alkaloid, but believes that its presence is not yet certainly proved.

Medical Properties and Uses. According to Dr. Buffington, when given to the lower animals in very large doses grindelia produces narcosis, with dilated pupils, slowing of the action of the heart from stimulation of the inhibitory nerves, and elevation of the blood-

pressure from stimulation of the vaso-motor centre. Dobroklowsky has found that on the isolated frog's heart it acts in small doses as a stimulant and in large doses as a paralyzant; he further states that it acts chiefly upon the motor nerves and muscles; but Buffington asserts that it paralyzes first the sensory nerve-trunks, then the sensory side of the spinal cord, and afterwards involves the motor nerve-trunks and cord. Grindelia is not used in practical medicine for its influence upon the circulation, but as an antispasmodic, especially in *asthma*, and in *bronchitis* when there is a distinct tendency to dyspnœa and bronchial spasm. It seems probable that it not only exerts an antispasmodic influence, but also stimulates the bronchial mucous membrane, and it may be confidently exhibited in chronic bronchitis, especially of the aged. It has been employed with asserted success in *whooping-cough*. Its active principles appear to be excreted from the kidneys: hence after large doses there are sometimes evidences of renal irritation, and in chronic *catarrh* of the *bladder* good has been effected by its stimulant influence upon the mucous membrane of the viscus. As a local application, grindelia has been employed with asserted advantage in *burns*, *vaginitis*, *genito-urinary catarrh*, etc., applied either in the form of a poultice or in solution.

GUAIACI LIGNUM. U. S., Br. Guaiacum Wood.

(GUĀ'IẠ-CĪ LĬG'NŬM—gwā'yą-sī.)

"The heart-wood of Guaiacum officinale, Linné, and of Guaiacum sanctum, Linné (nat. ord. Zygophylleæ)." *U. S.* "The heart-wood of Guaiacum officinale, Linn., or of Guaiacum sanctum, Linn." *Br.*

Lignum Guajaci, *P. G.;* Lignum Sanctum (vel Benedictum, vel Vitæ); Lignum Vitæ, Bois de Gayac, *Fr.;* Guajakholz, Franzosenholz, Pockenholz, *G.;* Legno Guaiaco, *It.;* Guayaco, *Sp.*

Guaiacum officinale. Willd. *Sp. Plant.* ii. 538; Woodv. *Med. Bot.* 557, t. 200; Carson, *Illust. of Med. Bot.* i. 25, pl. 17. This is a large tree, of very slow growth. When of full size it is from forty to sixty feet high, with a trunk four or five feet in circumference. The branches are knotted, and covered with an ash-colored striated bark. That of the stem is of a dark-gray color, variegated with greenish or purplish spots. The leaves are opposite, and abruptly pinnate, consisting of two, three, and sometimes four pairs of leaflets, which are obovate, veined, smooth, shining, dark green, from an inch to an inch and a half long, and almost sessile. The flowers are of a rich blue color, stand on long peduncles, and grow to the number of eight or ten at the axils of the upper leaves. The seeds are solitary, hard, and of an oblong shape.

G. sanctum, L., is distinguished from *G. officinale* by its five-celled fruit and its oblong or obliquely obovate or sometimes rhomboid-ovate leaflets, six to eight to each leaf. It grows in Cuba and some other of the West India Islands, and in the Bahama Islands. Its wood is smaller than that of *G. officinale*, and is said by Fée to be paler and less dense.

G. officinale grows in the West Indies, particularly in Hayti and Jamaica, and is found also in the warmer parts of the neighboring continent. All parts of the tree are possessed of medicinal properties; but the wood and the concrete juice only are official. The bark, though much more efficacious than the wood, does not enter commerce. *G. arboreum* of De Candolle has been said to furnish some of the guaiacum wood of commerce.

Guaiacum wood is imported from Hayti and other West India islands, in the shape of logs or billets, covered with thick gray bark, which presents on its inner surface, and upon its edges when broken, numerous shining crystalline points. These were supposed by Guibourt to be benzoic acid, by others a resinous exudation from the vessels of the plant; but Dr. Otto Berg has determined that they are crystals of calcium sulphate. The billets are used by turners for the fabrication of various instruments and utensils, for which the wood is well adapted by its extreme hardness and density. It is kept by the druggists and apothecaries in the state of shavings or raspings, which they obtain from the turners. It is commonly called *lignum vitæ*, a name which obviously originated from the supposition that the wood was possessed of extraordinary remedial powers.

Properties. Guaiacum wood is hard and heavy. The color of the sap-wood is yellow, that of the older and central layers greenish brown, that of the shavings a mixture of the two. It is said that when the wood is brought into a state of minute division its color is rendered green by exposure to the air, and bluish green by the action of nitric acid fumes; and the latter change may be considered as a test of its genuineness. (*Duncan.*) An easier test is a solution of corrosive sublimate, which, added to the shavings and slightly heated, causes a

bluish-green color in the genuine wood. (*Chem. Gaz.*, No. 80, Feb. 1846.) Guaiacum wood is almost without smell unless rubbed or heated, when it becomes odorous. When burnt, it emits an agreeable odor. It is bitterish and slightly pungent, but requires to be chewed for some time before the taste is developed. It contains, according to Trommsdorf, 26 per cent. of resin, and 0·8 of a bitter pungent extractive, upon both of which, probably, though chiefly on the former, its medicinal virtues depend. (See *Guaiaci Resina.*) It yields its virtues but partially to water. One pound of the wood afforded to Geiger two ounces of extract. "Guaiacum Wood is generally used in the form of raspings or turnings, which should be greenish-brown, containing few particles of a whitish color, and should acquire a dark bluish-green color on the addition of nitric acid." *U. S.*

Medical Properties and Uses. Guaiacum wood ranks among the stimulant diaphoretics. It is said to have been introduced to the notice of European practitioners by the natives of Hispaniola soon after the discovery of America. It was used in Europe so early as 1508, and attained great celebrity as a remedy for *lues venerea;* but the general professional verdict is that it has no distinct influence in *syphilis*, nor yet in *chronic rheumatism* and *gout*, *scrofula*, or *cutaneous eruptions*, against which it was formerly much used. It is usually exhibited in decoction, and in combination with other medicines, as in the compound decoction of sarsaparilla. An aqueous extract is directed by the French Codex.

GUAIACI RESINA. U. S., Br. Guaiac.

(GUĀ'IĄ-CĪ RĘ-ŞĪ'NĄ.)

"The resin of the wood of Guaiacum officinale, Linné (nat. ord. Zygophylleæ)." *U. S.* "The resin obtained from the stem of Guaiacum officinale, Linn., or of Guaiacum sanctum, Linn." *Br.*

Resina Guajaci, *P. G.;* Guaiacum; Guaiacum Resin; Résine de Gayac, *Fr.;* Guajak, Guajakharz, *G.;* Resina de Guajaco, *It.;* Resina de Guayaco, *Sp.*

For a description of *Guaiacum officinale*, see *Guaiaci Lignum*, p. 673.

Guaiac is the concrete juice of this tree. It is obtained in several different modes. The most simple is by spontaneous exudation, or by incisions made into the trunk. Another method is by sawing the wood into billets about three feet long, boring them longitudinally with an auger, then placing one end of the billet on the fire, and receiving in a calabash the melted guaiac, which flows out through the hole at the opposite extremity. But the plan most frequently pursued is probably to boil the wood, in the state of chips or sawdust, in a solution of common salt, and skim off the matter which rises to the surface. Guaiac is brought to this market from the West Indies. It is usually in large irregular pieces of various sizes, in which small fragments of bark, sand, and other impurities are mixed with the genuine guaiac, so as to give to the mass a diversified appearance. Sometimes we find it in small roundish homogeneous portions, separate or agglutinated; sometimes in homogeneous masses, prepared by melting and straining the drug in its impure state. It is probable that the guaiac obtained from the billets in the manner above described is of uniform consistence.*

Properties. The masses are irregular or somewhat globular, of a glassy lustre and resinous fracture. They are of a deep greenish-brown or dark-olive color on their external surface, and internally wherever the air can penetrate. The predominant hue of those parts not exposed to the air is reddish brown or hyacinthine, diversified, however, with shades of various colors. The odor is feeble but fragrant, and is rendered stronger by heat. The taste, which is at first scarcely perceptible, becomes acrid after a short period; and a permanent sense of heat and pungency is left in the mouth and fauces. Guaiac is brittle, and when broken presents a shining glass-like surface, conchoidal or splintery, with the smaller fragments more or less translucent. It is readily pulverized; and the powder, at first of a light-gray color, becomes green on exposure to the light. Its sp. gr. varies from 1·2 to 1·23. It softens in the mouth, and melts with a moderate heat. Water dissolves a small proportion of guaiac, not exceeding nine parts in 100, forming an infusion of a greenish-brown color and sweetish taste, which upon evaporation yields a brown substance soluble in hot water and alcohol, but scarcely so in ether. Alcohol takes up the whole, with the exception of impurities. "Soluble in potassium or sodium hydrate test-solution and in alcohol; the alcoholic solution

* Under the name of *Resina Guaiaci Peruviana Aromatica* there is a substance circulating in European commerce which probably has no relation to guaiac. For a summary of our knowledge concerning it, see *A. J. P.*, 1877, p. 18.

is colored blue on the addition of tincture of ferric chloride." *U. S.* The tincture is of a deep-brown color, is decomposed by water, and affords blue, green, and brown precipitates with the mineral acids. It is colored blue by nitric acid, by chlorine, and by tincture of ferric chloride, and usually by spirit of nitrous ether, and is similarly changed when treated successively by dilute hydrocyanic acid and solution of copper sulphate. Either in substance or tincture, guaiac gives a blue color to gluten and substances containing it, to mucilage of gum arabic, to milk, and to various freshly-cut roots, as the potato, carrot, and horseradish. It is soluble also in ether, alkaline solutions, and sulphuric acid. The solution in sulphuric acid is of a rich claret color, deposits, when diluted with water, a lilac precipitate, and, when heated, evolves charcoal. Exposed to air and light, guaiac absorbs oxygen and becomes green, and the change takes place rapidly in the sunshine. Tincture of guaiac has been used for the detection of blood-stains, which it does by the blue color produced by it, when in contact with the red coloring matter of blood, in connection with some ozonized substance, especially hydrogen peroxide. (*Guy's Hospital Reports*, 3d ser., xiii. 432.) It may be used also to distinguish the blood of man and other mammals, in which the corpuscles are non-nucleated, from that of other classes, as birds, fishes, and reptiles, which have nucleated corpuscles. The method of Dr. R. M. Bertolet may sometimes be advantageously used in jury trials. A microscopic preparation, duly mounted, is carefully irrigated with a simple tincture of guaiac resin, and then, under glass, exposed to the action of a very small quantity of an ethereal solution of hydrogen peroxide. The mammalian corpuscles will exhibit a uniform blue coloration throughout, of different shades in the different corpuscles, while, if the blood-corpuscle is nucleated, the nucleus is seen as a well-defined and deep-blue body, with a delicate violet-colored medium around it. (*Am. Journ. Med. Sci.*, Jan. 1874.)

The composition of guaiac resin was ascertained by Hadelich (*Journ. f. pr. Chem.*, 87, p. 335) to be as follows: guaiaconic acid 70·3 per cent., guaiaretic acid 10·5 per cent., guaiac beta-resin 9·8 per cent., gum 3·7 per cent., ash constituents 0·8 per cent., guaiacic acid, coloring matter (guaiac yellow), and impurities 4·9 per cent. Of these constituents, *guaiaretic acid*, $C_{20}H_{26}O_4$, was discovered by Hlasiwetz in 1859. It may be extracted from the crude resin by alcoholic potash or by quicklime, forming a crystalline salt with the former and an amorphous compound with the latter. The free acid is obtained by decomposing one of these salts with hydrochloric acid and crystallizing from alcohol. The crystals, which are soluble in ether, alcohol, benzol, chloroform, carbon disulphide, or acetic acid, but not in ammonia or in water, melt below 80° C., and may be volatilized without decomposition. They are not colored blue by oxidizing agents. If the mother-liquor from the potassium salt of the guaiaretic acid be decomposed with hydrochloric acid and the precipitate washed with water, ether will extract *guaiaconic acid*, $C_{19}H_{20}O_5$. This compound, discovered by Hadelich in 1862, is a light-brown amorphous substance, fusing at 100° C. It is without acid reaction, but decomposes alkaline carbonates, forming salts easily soluble in water and alcohol. It is insoluble in water, benzol, or carbon disulphide, but dissolves in ether, chloroform, acetic acid, or alcohol. With oxidizing agents it assumes a transient blue tint. After the extraction of the guaiaconic acid there remains a substance insoluble in ether, to which the name of *guaiac beta-resin* has been applied. Its composition does not appear to differ greatly from that of guaiaconic acid. *Guaiacic acid*, $C_{12}H_{16}O_6$, obtained in 1841 by Thierry, from guaiacum wood, or from the resin, crystallizes in colorless needles. Hadelich states that not more than one part in 20,000 can be obtained from the resin. Lucker (*Proc. A. P. A.*, 1894, 953), having reinvestigated guaiacum, states that it consists chiefly of three acids,—viz., *guaiacic*, $C_{20}H_{24}O_4$, occurring in crystals melting at 70° C.; *guaiaconic*, $C_{20}H_{24}O_5$, an amorphous body melting at from 73° to 76° C.; and *guaiacinic*, $C_{19}H_{20}O_6$. He considers all three of them to be probably condensation products from tiglic aldehyde and guaiacol. *Guaiac yellow*, the coloring matter of guaiac resin, was first observed by Pelletier. It crystallizes in pale yellow quadratic octahedra having a bitter taste, but is not a glucoside. Guaiac resin also yields interesting products on dry distillation. First, according to Hlasiwetz, is obtained *guaiacene*, C_5H_8O, at 118° C., next *guaiacol*, $C_6H_4\begin{cases}OCH_3\\OH\end{cases}$, being the methyl ether of pyrocatechin, at 205°–210° C., and with it *kreosol*, $C_6H_3(CH_3)_2OH$, and finally *pyroguaiacin*, $C_{38}H_{44}O_6$ (according to Wiesner, $C_{18}H_{18}O_3$), in pearly scales, melting at 180° C. According to Lieben and Zeisel (*Ber. d. Chem. Ges.*, xiv. p. 932), guaiacene is the aldehyde of tiglic acid, $C_5H_8O_2$, and can be made synthetically from a mixture of acetaldehyde and propionaldehyde. When distilled with zinc dust there is obtained *creosol* (50 per cent. in the case of resin purified by alcohol) and 30 per cent. of a mixture of

toluene, *meta-* and *paraxylene*, with a little *pseudocumene* and *guaion*, $C_{12}H_{12}$. (Bötsch, *Monatshefte*, 1880, 615.)

It will be inferred, from what has been said, that the mineral acids are incompatible with the solutions of guaiac.

Adulterations. This drug is sometimes adulterated with the resin of the pine. The fraud may be detected by the terebinthinate odor exhaled when the sophisticated guaiac is thrown upon burning coals, as well as by its partial solubility in hot oil of turpentine. This liquid dissolves resin, but leaves pure guaiac untouched. Amber is said to be another adulteration. Nitric acid affords an excellent test of guaiac. If paper moistened with the tincture be exposed to the fumes of this acid, it speedily becomes blue. Purgotti proposed guaiac resin as a test for copper. (See *A. J. P.*, June, 1880.)

Medical Properties and Uses. Guaiac is stimulant and alterative, producing, when swallowed, a sense of warmth in the stomach, with dryness of the mouth and thirst, and promoting various secretions. If given to a patient when covered warm in bed, especially if accompanied with opium and ipecacuanha or the antimonials, and assisted by warm drinks, it often excites profuse perspiration; and hence it has been usually ranked among the diaphoretics. If the patient be kept cool during its administration, it is sometimes directed to the kidneys, the action of which it promotes. In large doses it purges, and it has been especially commended as a laxative in chronic rheumatism; and it is thought by some practitioners to be possessed of emmenagogue powers. It has been given with asserted advantage in *chronic rheumatism*, *gouty affections*, secondary *syphilis*, *scrofulous diseases*, and *cutaneous eruptions*. The medicine is given in substance or tincture. The dose of the powder is from ten to thirty grains (0·65–1·95 Gm.), which may be exhibited in pill or bolus, in the shape of an emulsion formed with gum arabic, sugar, and water, or as a syrup.* An objection to the form of powder is that it quickly aggregates. Guaiac is sometimes administered in combination with alkalies, with which it readily unites. Several European Pharmacopœias direct a *soap of guaiac*, under the name of *sapo guaiacinus*, to be prepared by diluting liquor potassæ with twice its weight of water, boiling lightly, then adding guaiac gradually, with continued agitation, so long as it continues to be dissolved, and finally filtering, and evaporating to the pilular consistence. One scruple (1·3 Gm.) may be taken daily, in divided doses.

GUARANA. U. S. Guarana.

(GUĄ-RĀ'NĄ.)

"A dried paste chiefly consisting of the crushed or pounded seeds of Paullinia cupana, Kunth (Paullinia sorbilis, Martius) (nat. ord. Sapindaceæ)." *U. S.*

Paullinia, Brazilian Cocoa, Guarana Bread; Pao de Guarana, *Port.;* Pasta Guarana, *P. G.;* Guarana, *Fr., G.*

There are described of the genus Paullinia 121 species, all of them confined in their geographical range to tropical and subtropical South America, except one, which has strayed to Eastern and Western Africa, and two others which are found in Mexico and in the gardens of the Sandwich Islands. The name of the genus was given in honor of Christ. Fred. Paullini, a German medico-botanical writer, who died in 1712. *P. sorbilis.* Martius, *Reise in Brasil*, vol. iii. 1098; *B. & T.* 67.—*Guarana üva.* This woody climber grows in the northern and western provinces of Brazil, ripening its seeds in October and November. The leaves are alternate, on long stalks, impari-pinnate, with five oblong oval, coarsely irregularly sinuate-dentate leaflets, five to six inches long by two to three broad, contracted into a shortly attenuated blunt point. The flowers are arranged in axillary, spicate panicles, four inches or more in length. The fruit is about the size of a grape, ovoid or pyriform, on a short peduncle, with a short strong beak, glabrous, with six longitudinal ribs. The three-valved pericarp is thin, tough, and strongly hairy within.

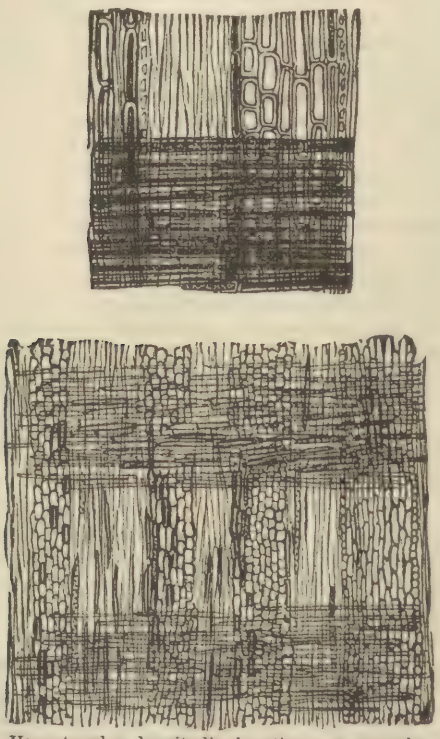
Preparation and Properties. The seeds, which look like small horse-chestnuts, are contained in a three-celled, three-valved, coriaceous capsule, are lenticular and almost thorny, and invested with a flesh-colored arillus, which is easily separable when dry. Guarana is made exclusively by the Guaranis, a tribe of South American Indians, and probably varies in the details of its preparation, as it certainly does in appearance and quality. The drug appears to

* *Syrup of Guaiac.* Dr. T. C. Craig. (*A. J. P.*, July, 1880.) Powd. Guaiac Resin, 640 grains; Caustic Potassa, 58 grains; White Sugar, ℔j (av.); Water, q. s. Dissolve the Potassa in 8 fluidounces of water; moisten the Guaiac with this solution; pack it in a percolator, and gradually pour on the remainder of the solution; when this ceases dropping, add sufficient water to make the percolate measure 8 fluidounces; add the sugar, and dissolve.

be produced almost exclusively from plants cultivated in the region of the lower Madeira and southward. After the seeds are shelled and thoroughly washed they are roasted for about six hours, and their external papery shells are then removed by placing them in sacks and beating them with clubs; or, after the seeds have been broken in a mortar, the coarse powder is mixed with a little water, and then kneaded into a paste, which is shaped into cylindrical or globular masses. According to Rusby, the common belief that at this stage various foreign bodies are added to the paste is incorrect. The masses are dried, sometimes in the sun, or more usually by the heat of a slow fire so arranged as to avoid smoke. When finished, the masses are of a reddish-brown color, rugose on the surface, very hard, with an irregular fracture, and of a marbled appearance when broken, due to the fragments of the seeds and their black testa embedded in the mass. Paullinia is of a somewhat astringent and bitterish taste, and in this, as well as in its odor, bears some resemblance to chocolate, though not oleaginous. It swells up and softens in water, which partially dissolves it. It is also partly soluble in alcohol. Martius found in it a crystallizable principle, which he named *guaranine*, but which has been proved by MM. Berthemot and Dechastelus to be identical with *caffeine*. Alexander Bennett, in an elaborate series of physiological experiments, has confirmed this identity.* The discovery of caffeine in plants belonging to distinct natural families, namely, the coffee and tea plants, the Paraguay tea, and the Paullinia, is a highly interesting result of recent chemical investigations. It is said to be more abundant in the Paullinia than in either of the other vegetables; 5·07 per cent. having been found by Dr. Stenhouse in Paullinia, while he got only 2·13 per cent. from good black tea, 1·00 from coffee, and 1·2 from Paraguay tea. (*P. J. Tr.*, xvi. 213.) According to Berthemot and Dechastelus, it exists in the seeds united with tannic acid, with which it appears to form two compounds, one crystallizable and soluble in water, the other of a resinoid appearance and insoluble. Besides these ingredients, the seeds contain free tannic acid, gum, albumen, starch, and a greenish fixed oil. (*Journ. de Pharm.*, xxvi. 514.) For a method of preparing guaranine, see *Journ. de Pharm.*, 4e sér., xviii. 224. Rochefontaine and Gusset prepare guaranine by mixing one part of calcined magnesia with five parts of powdered guarana, moistening with water, and, after standing 24 hours, exhausting the mass with boiling chloroform, evaporating the chloroform, treating the residue with boiling water, filtering, and evaporating over sulphuric acid. (*A. J. P.*, 1886, p. 248.) Dr. F. V. Greene, U.S.N., prefers a process for obtaining caffeine from guarana similar to one proposed by Prof. Wayne for its extraction from tea and coffee. The details of the method are as follows. The powdered guarana is intimately mixed with three times its weight of finely divided litharge, and the mixture boiled in distilled water, until, on allowing the temperature to fall below the boiling point, the insoluble portion is found to subside rapidly, leaving the supernatant liquid clear and without color. When cool, the clear liquid is filtered, and the precipitate is transferred to the filter and washed with boiling water, the washing to be continued as long as yellowish precipitates are produced with either phosphomolybdic acid solution, auric or platinic chloride. A stream of hydrogen sulphide gas is now passed through the filtrate, and the lead sulphide thus formed separated by filtration. The solution is evaporated on a water-bath to expel the excess of hydrogen sulphide, filtered to remove a trace of sulphur, finally evaporated to the crystallizing point, and the caffeine, which crystallizes out on cooling, removed from the mother-liquor and pressed between folds of bibulous paper. After being thus treated, the crystals will be found to be perfectly white. A shorter process for the assay of guarana is given by C. H. Lawall. (*A. J. P.*, 1897, 350.) Five Gm. of the drug and 5 C.c. of 16 per cent. ammonia water are placed in a separatory funnel of convenient size. After allowing the mixture to stand for thirty minutes, the alkaloid is shaken out with chloroform, using three portions of 20 C.c. each. Dr. F. V. Greene has shown that the tannic acid from guarana has different properties from that found in other plants, and proposes to call it *paullinitannic acid*. (*A. J. P.*, 1877, 390.) M. Fournier has found in paullinia, besides tannate of caffeine, the following principles: gum, starch, an acrid green fixed oil, a concrete volatile oil, an aromatic liquid volatile oil soluble in water with a little alcohol, another liquid volatile oil scarcely soluble in water, a peculiar principle not precisely determined, and tannic acid. (*Journ. de Pharm.*, Avril, 1861, 291.) Dr. E. R. Squibb examined commercial guarana, and obtained 4·38 per cent. of alkaloid from good specimens. On account of the uncertainty of the composition of guarana, he recommends fluid extract of green coffee as a substitute. (See PART II., *National Formulary;* also *Ephemeris*, 1884, 612.)

* This identity has been denied by Dr. T. J. Mays. (See H. C. Wood's *Therapeutics.*)

Medical Properties and Uses. The effects of guarana upon the system are chiefly those of its alkaloid, although it contains enough tannin to have an appreciable influence. It is habitually employed by the Indians, either mixed with articles of diet, as with cassava or chocolate, or in the form of drink, prepared by scraping it, and suspending the powder in sweetened water, precisely as other nations use teas, coffees, etc. It is also considered by the Indians useful in the prevention and cure of bowel complaints. Dr. Gavrelle, who was at one time physician to Dom Pedro, in Brazil, and there became acquainted with the virtues of this medicine, called the attention of the profession to it some years since in France. It is now used in medicine almost exclusively to give relief during a paroxysm of *migraine*, and in atonic *chronic diarrhœa*, taken three or four times a day. Dose of the powder, one or two drachms (3·9–7·8 Gm.), of the fluid extract, one fluidrachm (3·9 C.c.).



HÆMATOXYLON. U. S. (Br.) Hæmatoxylon. [Logwood.]

(HÆ-MĄ-TŎX'Y-LŎN.)

"The heart-wood of Hæmatoxylon Campechianum, Linné (nat. ord. Leguminosæ)." *U. S.*

Hæmatoxylon campechianum. Willd. *Sp. Plant.* ii. 547; Woodv. *Med. Bot.* 455, t. 163; Carson, *Illust. of Med. Bot.* i. 33, pl. 25. This is a tree of middle size, usually not more than

Hæmatoxylon, longitudinal section, as seen under high and low powers.

Hæmatoxylon, transverse section, as seen under high and low powers.

twenty-four feet high, though, under favorable circumstances, it sometimes rises forty or fifty feet. The trunk, seldom exceeding twenty inches in diameter, is often very crooked, and is covered with a dark rough bark. The branches are also crooked, with numerous smaller ramifications, which are beset with sharp spines. The sap-wood is yellowish, but the interior

layers are of a deep-red color. The leaves are alternate, abruptly pinnate, and composed of three or four pairs of sessile, nearly obcordate, obliquely nerved leaflets. The flowers, which are in axillary spikes or racemes near the ends of the branches, have a brownish-purple calyx and lemon-yellow petals. They exhale an agreeable odor, said to resemble that of the jonquil.

The tree is a native of Campeachy, the shores of Honduras Bay, and other parts of tropical America, and has become naturalized in Jamaica. The wood, which is the part used in medicine, is a valuable article of commerce, and largely employed in dyeing. It comes to us in logs deprived of the sap-wood and having a blackish-brown color externally. According to Mr. Louis Siebold, the ground or chipped logwood of commerce is unfit for use as a medicinal agent, because it has been prepared as a dyestuff by being exposed in large moist heaps until its hæmatoxylin has been converted by oxidation into hæmatein. As a coloring agent, for analytical purposes, this fermented logwood, according to Mr. Siebold, is much superior to the natural wood.

Properties. Logwood is hard, compact, heavy, of a deep-red color, becoming purplish black by exposure, internally brown-red, and marked with irregular, concentric circles, splitting irregularly, of a slight peculiar odor, and a sweet, somewhat astringent taste. Logwood is generally found in commerce in small chips or coarse powder of a dark brown-red color, often with a greenish lustre. When chewed it colors the saliva dark pink. It imparts its color to water and to alcohol. The infusion made with cold water, though red, is less so than that with boiling water. It affords precipitates with sulphuric, nitric, hydrochloric, and acetic acids, alum, copper sulphate, lead acetate, and ferrous sulphate, striking a bluish-black color with the last-mentioned salt. Precipitates are also produced with it by lime water and gelatin. Chevreul found in logwood a volatile oil, an oleaginous or resinous matter, a brown substance the solution of which is precipitated by gelatin (*tannin*), another brown substance soluble in alcohol but insoluble in water or ether, a nitrogenous substance resembling gluten, free acetic acid, various salts, and a peculiar principle called *hæmatoxylin* or *hématin*, on which the coloring properties of the wood depend. This is obtained by digesting the aqueous extract in alcohol, evaporating the tincture till it thickens, then adding a little water, and submitting the liquid to a new but gentle evaporation. Upon allowing it to rest, hæmatoxylin is deposited in crystals, which may be purified by washing with alcohol and drying. Thus procured, the crystals are shining, of a yellowish-rose color, bitterish, acrid, and slightly astringent to the taste, readily soluble in boiling water, forming an orange-red solution which becomes yellow on cooling, and soluble also in alcohol and ether. According to Erdmann, who obtained hæmatoxylin by the process of Chevreul, substituting ether for alcohol, its crystals, when quite pure, are colorless, without a tinge of redness; its taste is sweet, like that of liquorice, without bitterness or astringency; and it is not of itself a coloring substance, but affords beautiful red, blue, and purple colors, by the joint action of an alkaline base and the oxygen of the air. He obtained from logwood 9 to 12 per cent. of crystallized hæmatoxylin, to which he gave the formula $C_{16}H_{14}O_6$. It crystallizes with 1 or with 3 molecules of water, and is readily soluble in hot water or alcohol, but sparingly in cold water or in ether. (*Journ. für pr. Chem.*, 36, p. 205.) By the combined action of ammonia and oxygen dark violet crystalline scales of *hæmatein*, $C_{16}H_{12}O_6 + 3H_2O$, are produced. They show a fine green hue, which is also very commonly observable on the surface of the logwood chips of commerce. Hæmatein may again be transformed into hæmatoxylin by means of hydrogen or of sulphurous acid. Commercial extract of logwood extracted from the wood by boiling water contains both hæmatoxylin and hæmatein.

Medical Properties and Uses. Logwood is a mild astringent, devoid of irritating properties, and well adapted to the treatment of that relaxed condition of bowels which is apt to succeed *cholera infantum*. It is also occasionally used with advantage in ordinary *chronic diarrhœa* and *chronic dysentery*. The only official preparation is the extract. Dose, from ten to twenty grains (0·65–1·3 Gm.). *Hæmatoxylin* was found by Combemale (*Bulletin Méd. du Nord*, xxxiii. 1894) to be very feebly antiseptic, but capable in large doses of producing fatal gastro-enteritis in the lower animals.

HAMAMELIS. U. S. (Br.) Hamamelis. [Witchhazel.]

(HĂM-Ą-MĒ'LĬS.)

(HĂM-Ą-MĔL'Ị-DĪS CÖR'TĔX.)

"The dried bark of Hamamelis virginiana, Linn." *Br.*

Witchhazel Bark.

H. virginica. L. *Witchhazel* is an indigenous shrub, from five to fifteen feet high, growing in almost all sections of the United States, usually on hills or in stony places, and often on the banks of streams. It is the only species of the genus found in Eastern North America, and is specifically characterized by its leaves being obovate or oval, wavy-toothed, and somewhat downy when young. The seeds are black and shining externally, white, oily, and farinaceous within, and edible like the hazelnut. It is remarkable for the late appearance of its yellow flowers, which expand in September or October, and continue till the weather becomes very cold in winter. The fruit, which is a nut-like capsule not unlike the hazelnut, ripens in the following autumn, and is often mingled on the same plant with the new blossoms. According to Engler and Prantl, the correct name of the natural order is Hamamelidaceæ.

Properties. The leaves of the witchhazel are officially described as "short-petiolate, about 10 Cm. long, obovate or oval, slightly heart-shaped and oblique at the base, sinuate-toothed, thickish, nearly smooth; inodorous; taste astringent and bitter." *U. S.* The bark has a bitter, astringent, somewhat sweetish, and pungent taste. In the Br. Pharm. it is characterized as "Usually in curved pieces about one-sixteenth of an inch (one and a half millimetres) thick, and varying from two to eight inches (one-half to two decimetres) in length, sometimes covered with a silvery-gray or dark-gray scaly cork marked with transverse lenticels, but frequently freed from the cork, and then exhibiting a nearly smooth reddish-brown outer surface. The inner surface is pale reddish pink in color, and finely striated longitudinally; the fracture is laminated and coarsely fibrous. The Bark has an astringent taste, but no marked odor. The transverse section exhibits a complete ring of sclerenchymatous cells and numerous tangentially elongated groups of bast fibres."

Walter B. Cheney examined witchhazel bark, and found tannin, resin, extractive, but no indication of an alkaloid or other crystalline principle. (*A. J. P.*, 1886, p. 418.) It contains a trace of volatile oil, however. Dr. John Marshall, of the University of Pennsylvania, also found that hamamelis root contains tannic acid and a trace of volatile oil, but no other active substance. (*Therap. Gaz.*, ii. 295.)

Medical Properties. The bark of the witchhazel is said to have first attracted attention on account of its use by the North American Indians as a sedative application to external inflammations. It was many years ago strongly recommended by Dr. James Fountain and Dr. N. S. Davis (*N. Y. Journ. Med.*, x. 208; *Trans. Amer. Med. Assoc.*, i. 350) in *hemorrhage* of the *lungs* and *stomach*. Dr. Fountain also used with alleged great advantage an ointment prepared from lard and the decoction of equal parts of hamamelis, white-oak bark, and apple-tree bark. Of late years professional attention has been very strongly directed to the remedy on account of the enormous sale of a much vaunted proprietary remedy said to be made by distilling the bark with very dilute alcohol (six per cent.), and used externally for *sprains* and *bruises*, and internally for most of the diseases to which flesh is heir. The pecuniary success of this remedy probably has depended in very small part upon the virtues of the witchhazel, which seems to possess no active physiological properties. At least we have injected a very concentrated distillate in large quantities into frogs and into mammals without perceiving any more effects than would be produced by the injection of similar quantities of distilled water, and Dr. Guy, in Paris, has reached similar conclusions. The fluid extract of the drug has been used as a remedy in various forms of venous dilatation and engorgement. It was very strongly commended by Dr. John H. Musser in varicose veins (*Phila. Med. Times*, vol. xiii.), and has been used by some practitioners with good results in cases of hemorrhoids, but has failed to yield in other hands corresponding advantage. (See *Boston Med. and Surg. Journ.*, April 16, May, 1885; also *Bull. Gén. de Thérap.*, vol. cvi.) The dose of the fluid extract given by Dr. Musser was a teaspoonful four times a day. It may, however, be given in double the quantity with impunity, and probably in such doses is an advantageous astringent.

HEDEOMA. U. S. Hedeoma. [Pennyroyal.]

(HĔD-Ę-Ō'MĄ.)

"The leaves and tops of Hedeoma pulegioides (Linné), Persoon (nat. ord. Labiatæ)." *U. S.*

Herbe de Pouliot américaine, *Fr.*; Amerikanischer Poley, *G.*

This plant is entirely distinct from *Mentha pulegium*, or European pennyroyal. It is prob-

able that various other species of the genus are used in the localities in which they grow. Thus, *H. piperita*, Bentham, is said to be used in Mexico as a substitute for peppermint, and *H. thymoides*, Gray, in Texas as an aromatic diaphoretic.

Hedeoma pulegioides (L.), Pers. (1807); *Cunila pulegioides* L. (1762); *Melissa pulegioides* L. (1753). This is an indigenous annual plant, from nine to fifteen inches high, with a small, branching, fibrous, yellowish root, and a pubescent, quadrangular stem, which sends off numerous slender erect branches. The leaves are opposite, having short petioles, about half an inch long, oblong-lanceolate or oval, nearly acute, attenuated at the base, remotely serrate, rough or pubescent, and prominently veined and glandular on the under surface. The flowers are very small, pale blue, supported on short peduncles, and arranged in axillary whorls along the whole length of the branches. They have a tubular-ovoid, two-lipped and five-toothed calyx, and a pale blue, spotted, two-lipped corolla, containing two sterile and two fertile exserted stamens. The plant is common in all parts of the United States, preferring dry grounds, and, where abundant, scenting the air for a considerable distance with its grateful odor. Both in the recent and in the dried state it has a pleasant aromatic smell, and a warm, pungent, mint-like taste. It readily imparts its virtues to boiling water. The volatile oil upon which they depend may be separated by distillation, and employed instead of the herb itself. For the chemical nature of the oil, see *Oleum Hedeomæ*.

Medical Properties and Uses. American pennyroyal is a gently stimulant aromatic, and may be given in flatulent colic and sick stomach, or to qualify the action of other medicines. Like most of the aromatic herbs, it possesses the property, when administered in warm infusion, of promoting perspiration, and of exciting the menstrual flux when the system is predisposed to the effort. A large draught of the warm tea is in popular practice often given at bedtime, in recent cases of *suppression* of the *menses*, the feet having been previously bathed in warm water.

HEMIDESMI RADIX. Br. Hemidesmus Root.

(HĔM-Ĭ-DĔS'MĪ RĀ'DĬX.)

"The dried root of Hemidesmus indicus, R." *Br.*

Nunnari, *E.;* Racine de Hemidesmus, *Fr.;* Hemidesmus-Wurzel, *G.;* Indian Sarsaparilla.

Hemidesmus indicus. R. Brown, *Hort. Kew.* ii. 75; Lindley, *Flor. Med.* p. 543.—*Periploca indica.* Willd. *Sp. Plant.* i. 1251.—*Hemidesmus indicus* (Willd.), R. Br. Engler and Prantl. This is a climbing plant, with twining, woody, slender stems, and opposite petiolate leaves, which are entire, smooth, shining, and of a firm consistence. The leaves vary much in size and shape, some being linear and acute, others broad-lanceolate, and others again oval or ovate. The flowers are small, green on the outside, purple within, and disposed in axillary racemes. The calyx is five-parted, with acute divisions; the corolla flat, with oblong, pointed divisions. The fruit consists of two long, slender, spreading follicles.

This plant is common over the whole peninsula of Hindostan. The official portion is the root, which has long been used in India as a substitute for sarsaparilla. It is long, rarely more than one-quarter of an inch in diameter, rigid, tortuous, cylindrical, and little branched, consisting of a ligneous centre, and a brownish, corky bark, marked with longitudinal furrows and transverse fissures. The odor is aromatic, the taste sweetish. On one side of the root the cork is frequently separated from and raised above the cortex, and is transversely fissured. The transverse section exhibits numerous laticiferous cells in the cortex. For details of microscopic structure, see *P. J. Tr.*, 1872, 62. Mr. Garden obtained from hemidesmus a peculiar, volatilizable acid principle, which he named *smilasperic acid*, under the erroneous impression that the root was derived from *Smilax aspera*. Pereira proposed to call it *hemidesmic acid*. Scott (*Chem. Gazette*, 1843, 378) also obtained a stearopten by distillation with water, presumably the same material. It has not been further investigated.

Medical Properties and Uses. Indian sarsaparilla is said to be tonic, diuretic, and alterative. It was introduced into Great Britain from India, and was employed for some time under the name of *smilax aspera*. It is used for the same purposes as sarsaparilla. In some instances it is said to have proved successful in syphilis when that medicine had failed; but it cannot be relied on. The native practitioners in India are said to employ it in nephritic complaints, and in the sore mouth of children. It is used in the form of infusion or decoction, made in the proportion of two ounces of the root to a pint of water. A pint may be given in wineglassful doses in the course of the day. A syrup is directed in the British Pharmacopœia.

HIRUDO. Br. Leeches.

(HI-RŪ'DŌ.)

"1. Sanguisuga medicinalis, Savigny, the Speckled Leech; and 2. Sanguisuga officinalis, Savigny, the Green Leech." *Br.*

Hirudines, *P. G.;* Sangsue, *Fr.;* Blutegel, *G.;* Mignatta, *It.;* Sanguijuela, *Sp.*

HIRUDO. *Class* 1, Annelides. *Order* 3, Abranchiatæ. *Family* 2, Asetigeræ. *Cuvier.*

The leech belongs to that class of invertebrated articulated animals called *Annelides.* This class contains the worms with red blood, having soft retractile bodies composed of numerous segments or rings, breathing generally by means of branchiæ, with a nervous system consisting in a double knotted cord, destitute of feet, and supplying their place by the contractile power of their segments or rings. The third order of this class—*Abranchiatæ*—comprehends those worms which have no apparent external organ of respiration. This order is again divided into two families, to the second of which—the *Asetigeræ*, or those not having setæ to enable them to crawl—the leech belongs.

It is an aquatic worm with a flattened body, tapering towards each end, and terminating in circular flattened disks, the hinder one being the larger of the two. It swims with a vertical undulating motion, and moves when out of the water by means of these disks or suckers, fastening itself first by one and then by the other, and alternately stretching out and contracting its body. The mouth is placed in the centre of the anterior disk, and is furnished with three cartilaginous lens-shaped jaws at the entrance of the alimentary canal. These jaws are lined at their edges with fine sharp teeth, and meet so as to make a triangular incision in the flesh. The head is furnished with small raised points, supposed by some to be eyes. Respiration is carried on through small apertures ranged along the inferior surface. The nervous system consists of a cord extending the whole length, furnished with numerous ganglions. The intestinal canal is straight, and terminates in the anus, near the posterior disk. Although hermaphrodite, leeches mutually impregnate each other. They are oviparous; and the eggs, varying from six to fifteen, are contained in a sort of spongy, slimy cocoon, from half an inch to an inch in diameter. These are deposited near the edge of the water, and hatched by the heat of the sun. The leech is torpid during the winter, and casts off from time to time a thick slimy coating from its skin. It can live a considerable time in sphagnous moss or in moistened earth, and is frequently transported in this manner to great distances.

Savigny has divided the genus Hirudo of Linnæus into several genera. The true leech is the Sanguisuga of this author, and is characterized by its three lenticular jaws, each armed with two rows of teeth, and by having ten ocular points. Several species are used for medical purposes, of which the most common are the gray and the green leech of Europe, both of which are varieties of the *Hirudo medicinalis* of Linnæus; and the *Hirudo decora* of this country.

1. *Hirudo medicinalis.* Linn. *Ed. Gmel.* i. 3095.—*Sanguisuga officinalis.* Savigny, *Mon. Hir.* p. 112, t. 5, f. 1. *The green leech.—Sanguisuga medicinalis.* Savigny, *Mon. Hir.* p. 114, t. 5, f. 2. *The gray leech.* Many of the best zoologists regard the *Sanguisuga officinalis* and *S. medicinalis* of Savigny as mere varieties. They are both marked with six longitudinal dorsal ferruginous stripes, the four lateral ones being interrupted or tessellated with black spots. The color of the black varies from a blackish to a grayish green. The belly in the first variety is of a yellowish-green color, free from spots, and bordered with longitudinal black stripes. In the second it is of a green color, bordered and maculated with black. This leech varies from two to four inches in length. It inhabits marshes and running streams, and is abundant throughout Europe.*

* A variety of the leech has come into use in Europe, called in commerce *African leeches.* They are of a beautiful light-green color, varying to a deep green, and often inclining to red, with black points on the back, and broad streaks of a bright orange-yellow, which are black towards the abdomen. They correspond perfectly with the *Sanguisuga interrupta* of Moquin-Tandon. These leeches draw very well. (*P. J. Tr.*, x. 38.) The leeches from Algiers, called in French commerce *dragons* (*Sanguisuga troctena* of Moquin-Tandon), of which considerable numbers have been taken to France, are said by M. A. de Quatrefages, contrary to former opinion, to be quite equal to the European. (*Journ. de Pharm.*, 3e sér., xxxiii.) It is stated (*P. J. Tr.*, June, 1867) that great numbers of leeches are collected in Australia and sent to Melbourne, whence a large proportion are exported to Europe and America, chiefly to London and Paris in the former continent, and San Francisco, Panama, and New York in the latter. It is estimated that two or three millions annually pass through the hands of the Murray River Fishing Company. The leech is said (*Ibid.*, March, 1865) to abound in almost every river and lagoon in Australia, and to differ from the ordinary English leech only in that the olive streaks are much lighter in the former. They are collected by throwing into the water a fresh sheepskin, to which they attach themselves. They bear transportation wonderfully well. In Hindostan and the island of Ceylon, where the varieties of leeches are said to be more numerous than in any other part of the world, it is stated by Mr. P. L. Simmonds that the propagation of the kind used in medicine is carefully kept secret. (*P. J. Tr.*, Dec. 1870.)

The great use made of leeches in the modern practice of medicine has occasioned them to become a considerable article of commerce. They are collected in Spain, France, Italy, Germany, and Sweden, and carried in large numbers to London and Paris. They are also frequently brought to this country, as the practitioners in some of our large cities use only the foreign leech, although our own waters furnish an inexhaustible supply of this useful worm.* The indigenous leech was formerly much used in the city of Philadelphia.

2. *Hirudo decora.* Say, *Colonel Long's Second Expedition*, ii. 268. The medicinal leech of America has been described by Say under the name of *Hirudo decora*, in the Appendix to the Second Expedition of Colonel Long. Its back is of a deep pistachio-green color, with three longitudinal rows of square spots. These spots are placed on every fifth ring, and are twenty-two in number. The lateral rows of spots are black, and the middle range of a light brownish-orange color. The belly is of the latter color, variously and irregularly spotted with black. The American leech sometimes attains the length of four or five inches, although its usual length is from two to three. It does not make so large and deep an incision as the European leech, and draws less blood.

The proper preservation of leeches is an object of importance to the practitioner, as they are liable to a great and sudden mortality. They are usually kept in jars, in clear, soft water, which should be changed twice a week in winter and every other day in summer. The jar must be covered with a linen cloth, and placed in a situation not liable to sudden changes of temperature. They will live a long time and continue active and healthy without any other attention than that of frequently changing the water in which they are kept. M. Derheims has proposed the following excellent method of preserving them. In the bottom of a large basin or trough of marble he places a bed, six or seven inches deep, of a mixture of moss, turf, and fragments of wood. He strews pebbles above, so as to retain them in their place without compressing them too much or preventing the water from freely penetrating them. At one end of the trough, and about midway of its height, is placed a thin slab of marble or earthenware, pierced with numerous holes, and covered with a bed of moss, which is compressed by a thick layer of pebbles. The reservoir being thus disposed is half filled with water, so that the moss and pebbles on the shelf shall be kept constantly moist. The basin is protected from the light by a linen cover stretched over it. By this arrangement the natural habits of the leech are not counteracted. One of these habits, essential to its health, is that of drawing itself through the moss and roots to clear its body from the slimy coat which forms on its skin and is a principal cause of its disease and death. Mr. James Banes recommends that when kept in jars they should be cleansed by means of a whisk of very fine broom or willow, when the water is changed. M. Lahache, an apothecary at Bruyères, strongly recommends carrageen, or Irish moss (*Chondrus crispus*), as admirably adapted to the habits and wants of the leech, furnishing the animal, he supposes, with nutriment, as it does not die of inanition when thus kept. The water should be renewed in the jars daily. (*Journ. de Pharm. et de Chim.*, 4e sér., iii. 128.) Mr. Alfred Allchin keeps them in aquaria with growing water-plants and snails, which keep the water pure.† (*A. J. P.*, xxviii. 222.)

Medical Uses. Leeches afford the least painful and in many instances the most effectual means for the local abstraction of blood. They are often applicable to parts which, either from their situation or from their great tenderness when inflamed, do not admit of the use of cups, and in the case of infants are under all circumstances preferable to that instrument. They are indeed a powerful therapeutic agent, and give to the physician, in many instances, a control over disease which he could obtain in no other way.

In applying leeches to the skin, care should be taken to shave off the hair, if there be any, and to have the part well cleansed with soap and water, and afterwards with pure water. If the leech does not bite readily, the skin should be moistened with a little blood, or milk and water. It is said to bite more freely if the skin have been previously reddened by a sinapism and then washed perfectly clean. Sometimes the leech is put into a large quill open at both ends, and applied with the head to the skin until it fastens itself, when the quill is withdrawn. If it be desirable that the leech shall bite in a particular spot, this end may be attained by cutting a

* Attempts have been made, in France, on a large scale, to propagate leeches for sale. This is done by means of natural meadows, in which numerous small ponds are made, where the leeches, with certain cautions as to nourishment and preservation, multiply and grow so rapidly as to become a source of profit. In order that they may propagate, it is necessary that they should be fed on blood, which is given them either by causing animals, as horses, cows, etc., to be driven into the meadows, or by obtaining blood from slaughter-houses, and, after depriving it of fibrin by agitation, immersing the animals for a time in it while yet warm. (See *Journ. de Pharm.*, Jan. and Mai, 1854.)

† For other methods of keeping leeches, also for raising them, see *U. S. D.*, 14th ed., 472.

small hole in a piece of blotting-paper, and then applying this moistened to the skin, so that the hole shall be immediately over the spot from which the blood is to be taken. Leeches continue to draw blood until they are gorged, when they drop off.* The quantity of blood which they draw varies with the part to which they are applied, and the degree of inflammation existing in it. From the loose and vascular textures they will abstract more than from those which are firm and compact, and more from an inflamed than from a healthy part. As a rule, our leechers apply six for every fluidounce of blood. A single European leech will draw from half an ounce to an ounce. The quantity may often be much increased by bathing the wound with warm water. Leeches will continue to suck after their tails are cut off, which is sometimes done, although it is a barbarous practice.† It is said that they will draw better if put into cold beer, or diluted wine, and allowed to remain until they become very lively. They may be separated from the skin at any time by sprinkling a little salt upon them. After they drop off, the same application will make them disgorge the blood they have swallowed. Some leechers draw the leeches from the tail to the head through their fingers, and thus squeeze out the blood, after which all that is necessary is to put them in clean water, and change it frequently.‡ Leeches which are gorged with blood should be kept in a vessel by themselves, as they are more subject to disease, and often occasion a great mortality among the others. They should not be again used until they have recovered their activity. In cases where the bleeding from leech-bites continues longer than is desirable, it may be stopped by continued pressure, with the application of lint, by the use of collodium, or by touching the wounds with lunar caustic. A little cotton, impregnated with a saturated solution of alum in boiling-hot water, and, after it has become sufficiently cool, but before the alum has begun to crystallize, pressed upon the wound, will often prove effectual. Another mode of repressing the hemorrhage is to press upon the bite a piece of thin caoutchouc, previously softened upon one side by heat, so as to become adhesive. If lunar caustic be applied, the stick must first be brought to a fine point, which is to be inserted in the wound. Some have even recommended the use of a fine wire made red hot. When the part wounded is without a bony basis, pressure may be made by pinching the wound between the fingers. It may sometimes be necessary, in the case of a deep bite, to sew the wound, which is readily done with a single stitch of the needle, that need not penetrate deeper than the cutis.§

* As a very efficient mode of applying leeches, it is recommended, after having moistened the skin with pure warm water, to put the leeches into a tumbler half full of cold water, and by an adroit movement invert it upon the part. The leeches are said to attach themselves so rapidly that it seems to the patient as though they made but a single bite. When they are all attached, the glass is to be carefully removed, the water being absorbed, as it runs off on one side, by a sponge or linen cloths.

† Under the name of *bdellotomy*, a practice has been introduced into Germany, of making a small incision in the side of the leech while drawing. The blood escapes through the wound, and the animal will continue to suck for a long time, so that one will perform the office of many in the quantity of blood taken.

‡ MM. Soubeiran and Bouchardat, after numerous experiments upon the different modes of fitting the gorged leeches for use again, came to the conclusion that a carefully managed pressure is the best. Two conditions, however, are necessary to success; one that they should be disposed to disgorge the blood, and the other that they should be immersed in warm water previously to the stripping. The first object is effected by common salt. The following plan is recommended. The leeches are to be thrown into a solution of 16 parts of common salt in 100 of water, from which they are to be taken out one by one, and, being held by the tail, are to be dipped into water which feels hot to the hand, but yet can be borne by it, and then passed lightly between the fingers. Thus treated, they easily give up the blood. After being stripped, they should be placed in vessels containing fresh water, which should be renewed once a day. At the end of eight or ten days they are fit for reapplication. (*Journ. de Pharm.*, 3e sér., xi. 343 and 350.) It is said that in the French military hospitals a mixture of one part of vinegar with eight parts of water is preferred to salt water for promoting disgorgement. (*Lond. Med. Times and Gaz.*, Oct. 1856, p. 375.) It has been stated that if the leeches, after being stripped, be put into water sweetened with a little white sugar, and the solution be renewed several times, at intervals of six or twelve hours, they will speedily recover their activity, and may be reapplied two or three times in the course of a few days. Immersion in camphor water for a few moments is said by Mr. Boyce to cause them to vomit the blood. They should afterwards be put into clean water, to be changed in half an hour. Dr. Frodsham, of England, has found camphor water preferable to either salt water or diluted vinegar, for disposing the gorged leech to part with blood. M. Grannat, a French military pharmaceutist, has found the natural process of disgorging preferable to all others. He placed some gorged leeches in wooden tubs containing at the bottoms a little clay and water, and renewed the water every forty-eight hours. After eight days, the leeches, now in good health, were transferred to a pond prepared for the purpose, where they propagated. He put 1000 leeches in the pond, and at the end of a year had taken out 850 fit for service, without interfering with the reproduction. (*Journ. de Pharm.*, 3e sér., xx. 186.) M. Vayson's plan of preserving leeches has been highly recommended. It consists simply in putting them, after stripping, if they have been used, in an earthenware vessel of the shape of an inverted truncated cone, with holes in the bottom so small as to prevent the escape of the leech, and filled with turfy earth. After the introduction of the leech, the opening is to be closed with a coarse cloth. The vessel is then placed in a tub containing water four inches deep. If to be sent to a distance, the earth in the vessel should be moistened throughout.

§ An instrument has been invented called the *mechanical leech*, by which the attempt has been made to imitate the action of the leech in drawing blood. It consists essentially of two parts, one for making the puncture, and the other for abstracting blood through the agency of atmospheric pressure. In other words, it is a minute cupping instrument. (*Am. Journ. Med. Sci.*, xvi. 207.)

HOMATROPINÆ HYDROBROMIDUM. Br. Homatropine Hydrobromide.

$C_{16}H_{21}NO_3HBr$. (HŌ-MĂT-RŌ-PĪ'NÆ HŸ-DRŌ-BRŌ'MĮ-DŬM.)

Homatropine Hydrobromate.

"The hydrobromide, $C_{16}H_{21}NO_3,HBr$, of an alkaloid prepared from tropine." *Br.*

This alkaloidal salt was first admitted to the British Pharmacopœia in the additions of 1890. Homatropine, $C_{16}H_{21}NO_3$, is prepared by evaporating a mixture of tropine, $C_8H_{15}NO$ (obtained through the saponification of hyoscyamine), and *mandelic acid* (phenyl-glycollic), $C_6H_5.CH(OH)COOH$, with diluted hydrochloric acid; mandelic acid may be produced by acting on amygdalin with hydrochloric acid, or synthetically from benzaldehyde and hydrogen cyanide.

Homatropine hydrobromate is officially described as follows: "A white crystalline powder or aggregation of minute trimetric crystals, soluble in 6 parts of cold *water*, and in 133 parts of *absolute alcohol*. The solutions should be neutral to *litmus*. A dilute aqueous solution, when applied to the eye, powerfully dilates the pupil. Heated on platinum foil it fuses and burns without leaving an appreciable residue. If 0·2 cubic centimetre of *chloroform* be shaken with 1 cubic centimetre of a 10 per cent. aqueous solution, to which *solution of chlorine* has been cautiously added, the *chloroform* will assume a brownish color. A 2 per cent. aqueous solution yields no precipitate on the cautious addition of *solution of ammonia* previously diluted with twice its volume of *water*, but dilute *solution of potassium hydroxide* produces in it a white precipitate, soluble in excess of the reagent. *Solution of iodine* causes a brown and *test-solution of mercuric chloride* a white precipitate. If about 0·01 gramme be dissolved in a little *water* and the solution rendered alkaline with *solution of ammonia* and shaken with *chloroform*, the separated *chloroform* will leave on evaporation a residue which will turn yellow, and finally brick-red, when warmed with about 1·5 cubic centimetres of a 2 per cent. solution of *mercuric chloride* in a mixture of five volumes of *alcohol* (90 per cent.) and three volumes of *water*. When treated with *fuming nitric acid* and *potassium hydroxide*, as described under 'Atropina,' no reddish-violet coloration is developed (distinction from atropine), the residue becoming reddish yellow. It affords the reactions characteristic of hydrobromides." *Br.*

Medical Properties. Homatropine is stated to produce, when taken internally, symptoms somewhat similar to those caused by atropine, except that the pulse-rate is rendered more slow instead of more rapid. Experiments made upon the reptilian heart indicate that the slowness of the pulse and the fall of the arterial pressure which has been found to accompany it are due in large part or altogether to direct action upon the heart itself. No cases of fatal poisoning are, so far as we know, on record; but in experiments made upon the lower animals death has been found to be due to a centric respiratory paralysis.

Homatropine hydrobromide has not been used internally to any extent, but is largely employed as a local mydriatic, having the advantage over atropine of being much less irritating to the conjunctiva and much less prone to produce serious systemic disturbance. The pupil begins to dilate in from seven to twenty minutes after the instillation; accommodation fails in from forty to ninety minutes; whilst usually the recovery is complete in from one to three days. For simple dilatation of the pupil, a solution of the strength of four grains to the ounce is sufficient. When it is desired to paralyze accommodation completely, the 2-per-cent. solution may be employed. The internal dose directed by the Br. Pharm. is from one-eightieth to one-twentieth of a grain (0·0008–0·0032 Gm.).

HUMULUS. U. S. (Br.) Hops.

(HŪ'MŲ-LŬS.)

"The strobiles of Humulus Lupulus, Linné (nat. ord. Urticaceæ)." *U. S.* "The dried strobiles of Humulus Lupulus, Linn., from cultivated plants." *Br.*

Lupulus, *Br.;* Hop; Strobili Humuli, s. Lupuli; Hop; Houblon, *Fr.;* Hopfen, *G.;* Luppolo, *It.;* Lupulo, Hombrecillo, *Sp.*

Humulus lupulus. L. *Sp. Pl.* (1753), 1028; Willd. *Sp. Plant.* iv. 769; Bigelow, *Am. Med. Bot.* iii. 163. The root of the hop is perennial, and sends up numerous annual, angular, rough, flexible stems, which twine around neighboring objects in a spiral direction from left to right, and climb to a great height. The leaves are opposite, and stand upon long footstalks. The smaller are sometimes cordate; the larger have three or five lobes; all are serrate, of a deep green color on the upper surface, and, together with the petioles, extremely rough, with minute prickles. At the base of the footstalks are two or four smooth, ovate, reflexed stipules. The

flowers are numerous, axillary, and furnished with bracts. The male flowers are a yellowish white, and arranged in panicles; the female, which grow on a separate plant, are pale green, and disposed in solitary, peduncled aments, composed of membranous scales, ovate, acute, and tubular at the base. Each scale bears near its base, on its inner surface, two flowers, consisting of a roundish compressed germ, and two styles, with long filiform stigmas. The aments are converted into ovate membranous cones or strobiles, the scales of which contain, each, at its base, two small seeds, surrounded by a yellow, granular powder. The genus Humulus is placed with Morus and Cannabis in a separate order, Moraceæ, by Engler and Prantl.

The hop-plant is a native of North America and Europe. In parts of New England, New York, and Michigan it is extensively cultivated, and most of the hops consumed in the United States are supplied by those districts. England probably produces the largest quantity of hops in the world, with Germany next in order. The part of the plant used is the fruit or strobiles. These, when fully ripe, are picked, dried by artificial heat, packed in bales, and sent into the market under the name of hops.

Hops consist of numerous thin, translucent, veined, leaf-like scales, which are of a pale greenish-yellow color, and contain near the base two small, round, black seeds. They are officially described as "ovate, about 3 Cm. long, consisting of a thin, hairy, undulated axis, and many obliquely ovate, membranous scales, in the upper part reticulately veined, and towards the base parallel-veined, glandular, and surrounding a subglobular achene; color of the scales greenish, free from reddish or brownish spots; odor aromatic; taste bitter, aromatic, and slightly astringent." *U. S.* Though brittle when quite dry, they are pulverized with great difficulty. Their odor is strong, peculiar, somewhat narcotic, and fragrant; their taste very bitter, aromatic, and slightly astringent. Their aroma, bitterness, and astringency are imparted to water by decoction; but the first-mentioned property is dissipated by long boiling. The most active part of hops is a substance formed on the surface of the scales, and, in the dried fruit, existing in the state of very small granules. This substance was called *lupulin* by the late Dr. A. W. Ives, of New York, by whom its properties were first investigated and made generally known; though it was previously noticed by Sir J. E. Smith, of England, and M. Planche, of France. The scales themselves, however, are not destitute of virtues, and contain, as shown by MM. Payen and Chevallier, the same active principles as does lupulin, though in less proportion.*

Lupulinum. *U. S. Lupulin.* Although lupulin is official (see *Lupulinum*), its characteristics are described here in order that the constituents of hops may be all considered together. Lupulin is obtained by rubbing or threshing and sifting the strobiles, of which it constitutes from one-sixth to one-tenth by weight. It is in the state of a yellowish powder, mixed with minute particles of the scales, from which it cannot be entirely freed when procured by a mechanical process. It has the peculiar flavor of hops, and appeared to MM. Lebaillif and Raspail, when examined by the microscope, to consist of globules filled with a yellow matter, resembling in this respect the pollen of vegetables; but from the investigations of M. Personne it would seem to be of the nature of a gland, commencing in a cell formed among those of the epidermis, and, when fully developed, secreting a resinous matter. (*Journ. de Pharm.*, 3e sér., xxvi.) It is inflammable, and when moderately heated becomes somewhat adhesive. The odor of lupulinic

* Hops are often subjected in Germany to the fumes of burning sulphur, from the supposition that they keep better when thus treated. Besides, by being partially bleached by the process, old hops, which have suffered from time, having become darker, generally spotted, and weaker, assume a brighter appearance, as if fresher, and generally command a better price in the market. To detect the consequent presence of sulphurous acid, the brewers put a silver spoon in a mixture of hops and water, under the impression that it will produce a black stain upon the silver. But this test will answer only when applied within a fortnight after the use of the sulphur. A more delicate method is that of Dr. Heidenreich, who puts 20 or 30 cones of the hops in a flask with zinc and hydrochloric acid, and passes the hydrogen evolved through solution of lead acetate. If sulphurous acid be present, hydrogen sulphide will be produced, which will occasion a dark precipitate with the solution. But even this plan often fails when the hops have been kept more than three or four weeks. A modification of this test has been proposed by Dr. R. Wagner. For the solution of lead acetate used in Heidenreich's method there is to be substituted a solution of sodium nitroprusside, so weak as to have a very light brown color, to which have been added a few drops of solution of potassa. If the gas evolved contain the minutest proportion of sulphur, a violet color will be produced when the first bubble passes into the solution; and this will by a continuance of the process become a magnificent purple. The least trace of sulphurous acid may thus be found; but a few months after the sulphuring of hops none at all can be detected.

Hops are said to be sometimes threshed in order to separate the lupulin, which is sold separately. Their efficiency is thus, no doubt, greatly impaired. Hops thus treated have the scales more or less broken; and any parcel presenting this appearance is to be suspected. Hops often contain a variable quantity of lupulin, in consequence of the granules of this substance separating, especially on agitation, and seeking the lower portion of the mass, which thus becomes richer, while the upper is poorer. They should always be examined in reference to the lupulin they contain, and, if nearly or quite destitute of it, should be deemed of inferior value and not be used medicinally.

grains resides in the essential oil. This is obtained to the extent of 0·9 per cent. by distilling hops with water. Personne stated that it contained *valerol*, $C_6H_{10}O$, which passes into valerianic acid; the latter in fact occurs in the glands, yet, according to Mehn, only to the extent of 0·1 to 0·17 per cent. When distilled from the fresh strobiles the oil has a greenish color, but a reddish brown when old hops have been employed. It is devoid of rotatory power, neutral to litmus paper, and gives no remarkable coloration with concentrated sulphuric acid. The oil consists of a terpene, $C_{10}H_{16}$, boiling at 175° C., and an oil, $C_{10}H_{18}O$, boiling at 210° C. The bitter principle formerly called *lupulin* or *lupulite* was first isolated by Lermer (*Journ. für pr. Chem.*, 101), who called it the *bitter acid of hops* (*Hopfenbittersäure*). It crystallizes in large brittle rhombic prisms, and possesses the peculiar bitter taste of beer. Its composition is $C_{32}H_{50}O_7$. The main contents of the hop gland consist of wax (*myricyl palmitate* according to Lermer) and resins, one of which is crystalline and unites with bases. Besides the constituents of the glands, hops contain, according to Etti, *lupulo-tannic acid* and *phlobaphene*. The former is a whitish, amorphous mass, soluble in alcohol, hot water, or acetic ether, not in ether. By heating the humulo-tannic acid to 130° C., or by boiling its aqueous or alcoholic solution, it gives off water and is transformed into phlobaphene, a dark-red amorphous substance, $(C_{25}H_{24}O_{13})_2 - H_2O = C_{50}H_{46}O_{25}$. The latter substance, on boiling it with dilute mineral acids, again loses water, and furnishes glucose and *hop-red*, according to the reaction $C_{50}H_{46}O_{25} + 2H_2O = C_{38}H_{26}O_{15} + 2C_6H_{12}O_6$. From raw phlobaphene, ether removes the bitter principles of hops, a colorless crystallizable and a brown amorphous resin, besides chlorophyll and essential oil. (*Pharmacographia*, 2d ed.) The existence of a peculiar alkaloid in hops, suggested by Lermer in 1863, has been determined by Griessmayer. A concentrated decoction of hops was distilled with potassa or magnesia, the distillate neutralized with hydrochloric acid, evaporated to dryness, and treated with cold absolute alcohol to remove ammonium chloride; the alcoholic liquid was heated to boiling and cooled, when much trimethylamine chloride crystallized. The residuary liquid was filtered, the filtrate evaporated, first by a water-bath and then spontaneously, the residue was redissolved in water in a narrow cylinder, agitated with potassa and ether, and the ethereal liquid allowed to evaporate spontaneously. The remaining alkaline liquid had a peculiar odor recalling that of coniine, and a cooling but not bitter taste. It soon exhibited small crystals, and finally solidified completely. The author supposed that these crystals were impurities, and that the pure alkaloid is liquid or gaseous. He proposes for it the name of *lupuline*. (*A. J. P.*, 1874.) Lastly, Etti found arabic (pectic) acid, phosphates, nitrates, malates, citrates, and also sulphates, chiefly of potassium, to occur in hops. The amount of ash afforded by hops dried at 100° C. would appear to be on an average about 6–7 per cent. Dr. H. Bungener has isolated from hops a bitter crystalline substance, $C_{25}H_{35}O_4$, which is insoluble in water, but soluble in alcohol and alkaline solutions. He believes it to be identical with Lermer's hop-bitter acid, to be feebly acid, and to possess the character of an aldehyde. (*P. J. Tr.*, 1884.) A volatile oil has been found in hops, which was shown by Chapman to consist of two terpenes, $C_{10}H_{16}$ and $C_{10}H_{18}$, and an oxygenated constituent. (*Journ. Chem. Soc.*, 1893, 177, and *P. J. Tr.*, 1895, 211; see also *P. J. Tr.*, 1893, 988.)

Medical Properties and Uses. Hops are tonic and slightly narcotic, and have been highly recommended in diseases of general or local debility, associated with morbid vigilance or other nervous derangement. Diuretic properties have also been ascribed to them. The complaints in which they have been used are dyspepsia, and the nervous tremors, wakefulness, and delirium of drunkards.

An *infusion* prepared with half an ounce of hops and a pint of boiling water may be given in the dose of two fluidounces (60 C.c.) three or four times a day. The tincture is now the only official preparation of hops, but the alcohol probably acts more decidedly upon the system than the hops. (See *Tinctura Humuli.*) A pillow of hops has proved useful in allaying restlessness and producing sleep in nervous disorders. They should be moistened with water containing a trace of glycerin previously to being placed under the head of the patient, in order to prevent rustling. Fomentations with hops, and cataplasms made by mixing them with some emollient substance, are often beneficial in local pains and tumefactions.

The effects of hops may be obtained most conveniently by the use of *lupulin*, though Dr. Fronmüller, having after two trials with it obtained no soporific effect, denies it a place among the narcotics with hypnotic properties. (*B. and F. Med.-Chir. Rev.*, April, 1867, pp. 526–7.) Lupulin is a very feeble antaphrodisiac, and was formerly used as such in irritated conditions of the genito-urinary apparatus, also in irritable bladder. The dose of lupulin is from six to twelve grains (0·4–0·8 Gm.), given in capsules or in pills, which may be made by simply rubbing

the powder in a warm mortar till it acquires the consistence of a ductile mass, and then moulding it into the proper shape.* Lupulin may be incorporated with poultices, or formed into an ointment with lard, and used externally for the same purposes as hops.

HYDRARGYRI CHLORIDUM CORROSIVUM. U. S. (Br.) Corrosive Mercuric Chloride. [Corrosive Chloride of Mercury. Corrosive Sublimate.]

$HgCl_2$; 270·54. (HĬ-DRĂR′ĢĬ-RĪ ĊHLŌ′RĪ-DŬM CŌR-RŌ-SĪ′VŬM.) $HgCl_2$; 270·5.

"A salt, $HgCl_2$, obtained as a sublimate by heating a mixture of mercuric sulphate, sodium chloride, and a little black oxide of manganese." *Br.*

Hydrargyri Perchloridum, *Br.*, Mercuric Chloride; Hydrargyrum Bichloratum Corrosivum, *P. G.;* Sublimatus Corrosivus Chloruretum (Chloretum) Hydrargyricum, Hydrargyrum Corrosivum Sublimatum, Hydrargyri Bichloridum; Corrosive Chloride of Mercury, Perchloride of Mercury, Bichloride of Mercury; Deuto-chlorure de Mercure, Sublimé corrosif, Chlorure mercurique, *Fr.;* Aetzendes Quecksilberchlorid, Aetzender Quecksilbersublimat, *G.*

The former official processes for this salt will be found in the foot-note.†

The names given in the two Pharmacopœias to this important chloride do not exactly correspond. It is called corrosive mercuric chloride in the U. S. Pharmacopœia, and perchloride of mercury in the British. We prefer the former, as indicating, beyond any possibility of mistake, the article intended, as well as its corrosive property. Perchloride and subchloride are hardly sufficiently distinctive, when a mistake may be so serious as that of confounding corrosive sublimate and calomel. In the first British Pharmacopœia corrosive sublimate was recognized as the official title, which was a sufficient guarantee of security; but, unfortunately, it was deemed proper, immediately after the official title, and in close connection with it, to define the salt as chloride of mercury, in conformity with the view, adopted in that work, of the atomic weight of mercury. With many persons calomel is still the chloride of mercury, so that there is some chance that, should calomel be prescribed by this title, corrosive sublimate may be dispensed for it, with dangerous if not fatal effects to the patient. Indeed, death has at least in one recorded instance occurred in consequence of this confusion of nomenclature; and our official guides should take especial care to guard against such mistakes, instead of contributing to them.

Preparation and Properties. The first step in making corrosive sublimate is to form mercuric sulphate, by heating sulphuric acid and the metal together in an iron pot so arranged as to carry off the unwholesome fumes of sulphurous oxide, which are copiously generated. The dry salt obtained is then mixed with common salt, and the mixture sublimed in an iron pot lined with clay and covered by an inverted earthen pan. The late Dr. A. T. Thomson, of London, took out a patent for forming corrosive sublimate on the large scale, by the direct combination, by combustion, of gaseous chlorine with heated mercury. The product is stated to be perfectly pure, and to be afforded at a lower price than the sublimate made in the usual way. In order that the combination may take place, the mercury need not be heated to its boiling point, but only to a temperature between 149° C. and 204° C. (300° and 400° F.). According to Dr. Maclagan, corrosive sublimate made by this process is liable to the objec-

* Dr. Dyce Duckworth, of St. Bartholomew's Hospital, London, recommends, as the result of his own observation, the aromatic spirit of ammonia as a better solvent of lupulin than any other yet proposed. He offers the following formula: "Lupulin ℥ij, Aromatic Spirit of Ammonia Oj. Macerate for seven days, with occasional agitation, then filter, and add sufficient of the menstruum to make up a pint. The dose of this *Tinctura Lupulinæ Ammoniata* is from ♏xx to f℥j." (*P. J. Tr.*, Oct. 1868.)

† "Take of Mercury *twenty-four troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces.* Boil the Mercury with the Sulphuric Acid, by means of a sand-bath, until a dry white mass is left. Rub this, when cold, with the Chloride of Sodium in an earthenware mortar; then sublime with a gradually increasing heat." *U. S.* 1870. "Take of Persulphate of Mercury *twenty ounces* [avoirdupois]; Chloride of Sodium, dried, *sixteen ounces* [av.]; Black Oxide of Manganese, in fine powder, *one ounce* [av.]. Reduce the Persulphate of Mercury and the Chloride of Sodium each to fine powder, and, having mixed them and the Oxide of Manganese thoroughly by trituration in a mortar, put the mixture into an apparatus adapted for sublimation, and apply sufficient heat to cause vapors of perchloride of mercury to rise into the less heated part of the apparatus which has been arranged for their condensation." *Br.* 1885.

In order to understand the above processes, which are the same in principle, it is necessary to premise that corrosive sublimate is mercuric chloride, consisting of two atoms of chlorine and one atom of mercury. By boiling sulphuric acid in excess with mercury to dryness, a white salt (mercuric sulphate) is formed, according to the reaction $2H_2SO_4 + Hg = HgSO_4 + SO_2 + 2H_2O$. (See *Hydrargyri Persulphas.*) When this is mixed with sodium chloride (common salt), and the mixture exposed to a subliming heat, a mutual decomposition takes place, according to the reaction $HgSO_4 + (NaCl)_2 = Na_2SO_4 + HgCl_2$. The mercuric chloride thus formed sublimes, and the sodium sulphate remains behind. The quantities for mutual decomposition are two mols. of sodium chloride and one mol. of mercuric sulphate. The British formula differs from that of the U. S. P. 1870 in ordering mercuric sulphate ready formed, instead of preparing it as the first step of the process, and in the use of a small proportion of manganese dioxide, intended to convert into mercuric any mercurous salt that may be in the sulphate, and thus prevent the formation of mercurous chloride. (See *Hydrargyri Persulphas.*)

tion that a proportion of calomel is always formed, occasionally amounting to 10 per cent. It may sometimes be useful to know how to make a small quantity of corrosive sublimate on an emergency. This may be done by dissolving mercuric oxide (red precipitate) in hydrochloric acid, evaporating the solution to dryness, dissolving the dry mass in water, and crystallizing. Here a double decomposition takes place, resulting in the formation of water and the chloride.

Corrosive mercuric chloride is officially described as in "heavy, colorless, rhombic crystals, or crystalline masses, odorless, and having an acrid and persistent, metallic taste; permanent in the air. Soluble, at 15° C. (59° F.) in 16 parts of water, and in 3 parts of alcohol; in 2 parts of boiling water, 1·2 parts of boiling alcohol, 4 parts of ether, and about 14 parts of glycerin. It fuses at 265° C. (509° F.) to a colorless liquid, and at about 300° C. (572° F.) it volatilizes in dense, white vapors, leaving no residue. The aqueous solution reddens blue litmus paper, but becomes neutral to litmus on the addition of sodium chloride. With ammonia water it yields a white precipitate; with an excess of hydrogen sulphide a black one; with potassium iodide test-solution a red one, soluble in an excess of the reagent; and with silver nitrate test-solution a white precipitate, insoluble in nitric acid. If a saturated, aqueous solution of the salt be heated nearly to boiling, then completely saturated with hydrogen sulphide, and allowed to stand for several hours in a well-corked flask, it should yield a colorless filtrate which, on evaporation, should leave no residue (absence of many *foreign salts*). If the precipitated mercuric sulphide obtained in the last test be washed with water, then shaken for a few minutes with ammonia water, and filtered, the filtrate should be colorless, and, on the addition of a slight excess of hydrochloric acid, should afford neither a yellow color nor a yellow precipitate (absence of *arsenic*)." *U. S.* "Heavy colorless masses of prismatic crystals, possessing a highly acrid metallic taste. Soluble in 16 parts of cold and 2 parts of boiling *water*, 3 parts of *alcohol* (90 per cent.), 4 parts of *ether*, and, on trituration, in 2 parts of cold *glycerin*. It affords the reactions characteristic of mercuric salts and of chlorides. When heated it sublimes without decomposition, leaving only a trace of fixed residue. When heated with excess of *lime* it yields 72·8 to 73·8 per cent. of metallic mercury." *Br.*

Ether is capable of removing corrosive sublimate, to a considerable extent, from its aqueous solution when agitated with it. According to M. Mialhe, ether will not dissolve it when accompanied by a considerable quantity of mercuric oxide and a chloride of an alkalifiable metal. Sulphuric, nitric, and hydrochloric acids dissolve it without alteration. When heated it melts, and readily sublimes in dense, white, acrid vapors, which condense, on cool surfaces, in white, shining needles. Its aqueous solution renders green the syrup of violets, and is precipitated brick-red, becoming yellow, by the fixed alkalies and alkaline earths, and white by ammonia. (See *Hydrargyrum Ammoniatum*.) The former precipitate is mercuric oxide, which has the property of evolving oxygen and of being reduced to metallic globules when exposed to heat. This oxide is formed in the process for preparing *aqua phagedænica*, called also *lotio flava*, or *yellow wash*, which is obtained by mixing half a drachm of corrosive sublimate with a pint of lime water. (See *Lotio Flava*, *N. F.*) Corrosive sublimate forms, with ammonium chloride and sodium chloride, compounds which are more soluble than the uncombined mercurial salt. It is on this account that aqueous solutions of sal ammoniac or of common salt dissolve much more corrosive sublimate than simple water. The combination of corrosive sublimate with ammonium chloride was formerly called *sal alembroth*, or *salt of wisdom*. According to F. Hinterberger, corrosive sublimate is capable of combining with quinine and cinchonine. (*Chem. Gaz.*, ix. 211.) By dissolving one part of corrosive sublimate and a hundred parts of common salt in distilled water and evaporating to dryness, a soluble preparation is obtained which does not coagulate albumen. (*A. J. P.*, xliv. 11.) J. F. Brown (*Chem. and Drug.*, 1896, 425) recommends for dispensing purposes a solution of mercuric chloride of such strength that ten minims contain one grain, made by dissolving ninety-six grains of corrosive sublimate in one and a half ounces avoirdupois of glycerin and six fluidrachms of distilled water by the aid of heat, then cooling the solution and adding distilled water until the solution measures two fluidounces.

Test of Purity and Incompatibles. Pure corrosive chloride of mercury sublimes, when heated, without residue, and its powder is entirely and readily soluble in ether. Consequently, if a portion of any sample should not wholly dissolve in ether, or if it should not evaporate entirely, the presence of some impurity is proved. If calomel be present, and it frequently is, it will not be wholly soluble in water.* Arsenic is reported to be a frequent

* M. Bullot, having noticed in some corrosive sublimate an insoluble portion consisting of minute yellowish granules, found on examination that it was an aniline product. He surmised that the drug had been thrown into commerce after having been used in the preparation of aniline dyes. (*Journ. de Pharm.*, 4e sér., xviii. 414.)

impurity in corrosive sublimate. (See paper by J. Granville Smith, *A. J. P.*, 1877, p. 397.) It can be readily detected by the test of U. S. P. 1880. (See p. 689.) Corrosive sublimate is incompatible with many of the metals, the alkalies and their carbonates, soap, lime water, tartar emetic, silver nitrate, the lead acetates, the potassium and sodium sulphides, the soluble iodides, and all the sulphydrates. It is decomposed by many vegetable and some animal substances. According to Dr. A. T. Thomson, it produces precipitates in infusions or decoctions of chamomile, horseradish, columbo, catechu, cinchona, rhubarb, senna, simaruba, and oak bark. MM. Mialhe and Lepage have shown that corrosive sublimate is slowly converted into calomel by syrup of sarsaparilla and syrup of honey, but is not changed by contact with pure syrup. Dr. Samuel Kennedy (*Pharm. Record*, 1888, p. 201) proved conclusively that when corrosive sublimate was dissolved in compound syrup of sarsaparilla, as frequently prescribed, precipitation invariably occurred. He found that if sodium chloride in quantity equalling that of the mercurial used were added, precipitation was greatly retarded.

Medical Properties and Uses. Corrosive sublimate is a very powerful preparation, operating quickly, and, if not properly regulated, producing violent effects. It is less apt to salivate than most other mercurials. In doses of $\frac{1}{100}$ to $\frac{1}{60}$ of a grain (0·0006 to 0·0011 Gm.) it often seems to act as a tonic to the general nutrition, and even in somewhat larger dose it may exert its peculiar influence without any obvious alteration of the vital functions, except, perhaps, a slight increase in the frequency of the pulse, and in the secretions from the skin and kidneys. Sometimes, however, it purges; but this effect may be obviated by combining it with a little opium. In larger doses it occasions nausea, vomiting, griping pain in the bowels, diarrhœa, and other symptoms of gastric and intestinal irritation, and in still larger quantities produces all the effects of a violent corrosive poison. It has long been used as a remedy in *syphilis*, in all stages of which it has been highly recommended. It is especially useful in the advanced stages of the disorder, when there is no cachexia. When a very rapid impression is desired it is not as useful as calomel. It is also used advantageously in some chronic cutaneous affections, and in obstinate *chronic rheumatism*. It is usually associated with alterative or diaphoretic medicines, such as the antimonials, and the compound decoction or syrup of sarsaparilla; and, in order to obviate the irritation it is apt to produce, it may often be advantageously united with opium. There is no doubt that many of the substances in connection with which it is employed alter its chemical condition; but it does not follow that even in its altered state it may not be very useful as a remedy.

Externally employed, corrosive sublimate is stimulant, escharotic, and germicidal. A solution in water, containing from one-eighth to one-half grain in the fluidounce, is employed as an injection in *gleet*, and as a collyrium in chronic *venereal ophthalmia*. A stronger solution, containing one or two grains in the fluidounce, is an efficacious wash in *lepra* and other scaly eruptions. Dissolved in water, in the proportion of five to ten grains to the fluidounce, it may be used with much benefit in *venereal ulcers* of the throat, to which it should be applied by means of a camel's-hair pencil. With lime water it forms the *aqua phagedænica* of the older writers, employed as a wash for ill-conditioned ulcers. The powdered chloride has been used as an escharotic, but is, in general, inferior to silver nitrate or caustic potassa. In *onychia maligna*, however, it is employed with great advantage, mixed with an equal weight of zinc sulphate, and sprinkled thickly upon the surface of the ulcer, which is then to be covered with a pledget of lint saturated with tincture of myrrh. The whole diseased surface is thus removed, and the ulcer heals.* This practice originated, we believe, with the late Dr. Perkins, of Phila-

* *Antiseptic Dressings.* The following directions are given in *Pharm. Rundschau*, Prague, for antiseptic dressings to be used in the German army:

Corrosive Sublimate Gauze. Dissolve 50 Gm. mercuric chloride in 5000 Gm. alcohol, and add 7500 Gm. distilled water, 2500 Gm. glycerin, and 0·5 Gm. fuchsin, the latter being added for the purpose of readily distinguishing the corrosive sublimate gauze from others. Four hundred metres of gauze are well kneaded in this solution and allowed to soak for fifteen minutes; the gauze is then strongly pressed and well dried on wash-lines, being protected from light and dust.

Corrosive Sublimate Cotton. Absorbent cotton is soaked in the above solution and dried in loose layers. It has been stated that the cotton has a dissociating effect upon the mercuric chloride, mercury being fixed upon the cotton as oxide, a certain proportion of mercurous chloride being formed at the same time. (*A. J. P.*, 1893, 451.)

Corrosive Sublimate Catgut. A 5-per-cent. aqueous solution of corrosive sublimate is prepared, in which thin catgut is soaked for about eight hours, and the thicker kinds for ten or twelve hours. The catgut is subsequently kept in vials with alcohol.

Corrosive Sublimate Silk is prepared by soaking well-washed ligature silk in a solution of 5 parts of corrosive sublimate in 100 parts of water and 20 parts of glycerin. After drying it is wrapped in oiled silk or other waterproof material; and, before using, it is dipped into a 3-per-cent. phenol solution, or a 1-per-cent. solution of corrosive sublimate.

delphia, and was highly recommended by Dr. Physick. Dr. Geo. B. Wood often employed it with success. A solution of corrosive sublimate in collodion (four parts to thirty) has been used as a caustic, for the destruction of *nævi materni*, and for other purposes. It can be very accurately applied, but its use requires care, as fatal poisoning has followed a single application of the alcoholic solution of corrosive sublimate to a moderate surface of *ringworm*. (*London Lancet*, 1871, ii. 413.) It is applied by means of a camel's-hair pencil.

The dose of corrosive sublimate is from the one-hundredth to the eighth of a grain (0·0006 to 0·007 Gm.), preferably given after meals, in pill or solution. The pill is usually prepared with crumb of bread; care should be taken that the medicine be equally diffused through the pilular mass before it is divided.

Corrosive sublimate is one of the most powerful of known germicides, a solution of one part of it in twenty thousand in water being sufficient to kill micrococci and bacilli in active growth; whilst a solution of one in one thousand will rapidly destroy bacterial spores. According to Koch, as little as one part of corrosive sublimate in three hundred thousand of a proteid solution will prevent the generation of the spores of the bacillus of anthrax. As, however, ammonia and several other chemical substances habitually found in masses of filth rapidly decompose mercuric chloride, the latter is scarcely available for most disinfectant purposes on a large scale. For the purposes of antisepsis in surgery, however, corrosive sublimate is probably the most generally useful and effective of the known germicides. The solution of one in one thousand may be used for washing the hands, disinfecting furniture, etc., and is even employed in the disinfecting of wounds; usually, however, a much weaker solution than that just mentioned is employed by the surgeon. It is very rarely if ever justifiable to use upon a mucous surface or a wound a solution stronger than one in two thousand, and if the solution is to be used freely and continuously, as in washing out the vagina, etc., one in ten thousand is as strong as should be employed; indeed, the employment of a vaginal wash of this strength has been followed by violent poisoning. In a number of cases a solution of one part in fifteen hundred used locally by the surgeon has produced death, preceded by constitutional symptoms.

For the purpose of convenience to surgeons, *corrosive sublimate tablets* are now largely prepared and used. The amount of corrosive sublimate in these tablets should be so calculated as to yield, with the measures of water ordinarily used, solutions of convenient strength. Thus, if each tablet contains 7·3 grains of corrosive sublimate, one tablet dissolved in a pint of water will yield a solution of one in one thousand. Tablets are found in the market one-half this strength, one tablet making only half a pint of 1–1000 solution. In order to make the tablets readily soluble, the corrosive sublimate is usually compressed with some powdered ammonium chloride or tartaric acid: it is asserted of the latter addition, upon the authority of Prof. Laplace, that tartaric acid prevents the precipitation of the mercury as an insoluble albuminate. The proportions used by the manufacturers are as follows: 7·7 grains of corrosive sublimate and 7·3 grains of ammonium chloride in each tablet, one tablet making one pint of 1–1000 solution. The tablets containing tartaric acid are usually made one-half this strength, as follows: 3·85 grains of corrosive sublimate and 19·25 grains of tartaric acid in each tablet. It is essential that the tablets be colored or in some way marked so that the attention may be drawn to their nature, and accidental poisoning prevented.

Toxicological Properties. Swallowed in poisonous doses, it produces burning heat in the throat, excruciating pain in the stomach and bowels, excessive thirst, anxiety, nausea and frequent retching with vomiting of bloody mucus, diarrhœa and sometimes bloody stools, small and frequent pulse, cold sweats, general debility, difficult respiration, cramps in the extremities, faintings, insensibility, convulsions, and death. The mucous membrane of the stomach exhibits, on dissection, signs of the operation of a violent corrosive poison. These symptoms are sometimes followed or conjoined with others indicating an excessive mercurial action upon the system, such as inflammation of the mouth and salivary glands, profuse salivation, fetid breath, etc. The chief symptom of corrosive sublimate poisoning which distinguishes it from poisoning by antimony, arsenic, or other corrosive metallic irritant is the fact that the stools are very frequent, smallish, and composed chiefly of mucus and blood. A case is on record of death, in an infant, from the constitutional effects of corrosive sublimate sprinkled upon an excoriated surface; and in two instances of children, the one seven and the other nine years old, death, with all the symptoms of internal poisoning, followed the application to the scalp of an ointment said to consist of one part of the corrosive chloride to four parts of tallow. (*Dub. Quarterly*, Aug. 1854.) In the inferior animals, in whatever mode introduced into the

system, it produces symptoms and lesions similar to those which it causes in man. In the treatment of poisoning by corrosive sublimate, Orfila recommends the free use of the white of eggs beaten up with water. The albumen forms an insoluble and comparatively innocent compound with the corrosive sublimate; and the liquid by its bulk dilutes the poison, and distends the stomach so as to produce vomiting. It is, however, asserted by M. Lassaigne that this compound of albumen and corrosive sublimate, when recently precipitated, is soluble in acid and alkaline liquids, and in solutions of potassium, sodium, and calcium chlorides. (See *Journ. de Pharm.*, xxiii.) It is also soluble in an excess of albumen, whether introduced into the stomach or previously existing there. It is, therefore, important, at the same time that the antidote is used, to evacuate the stomach before the newly formed compound can be dissolved. If eggs cannot be procured, wheat flour may be substituted, gluten having, according to M. Taddei, the same effect as albumen. Milk also has been recommended, in consequence of the insoluble compound which casein forms with the poison. Besides the antidotes mentioned, Peruvian bark, meconic acid, ferrous sulphide, and iron filings have been proposed, all of which have the property of decomposing corrosive sublimate. The ferrous sulphide was found quite successful by M. Mialhe in experiments upon dogs, if given immediately after the poison was swallowed, but failed when delayed for ten minutes. Dr. T. H. Buckler, of Baltimore, made some successful experiments on lower animals upon the antidotal properties of a mixture of gold dust and iron filings (*Med. and Surg. Journ.*, 1843); and a case of poisoning by corrosive sublimate has been recorded by Dr. C. Johnston, of the same city, in which this antidote was employed with the apparent result of saving life, after albumen had been used without effect. Dr. Johnston, however, employed the reduced iron of the Pharmacopœia, and gold leaf, arranging them in alternate layers, so as to make boluses of convenient size. (*Am. Journ. of Med. Sci.*, April, 1863.) The method of operation of this antidote will be understood when the action of gold and iron as a test for corrosive sublimate is explained in the succeeding paragraph. It is of the utmost importance that whatever antidote is used should be given without delay, and in this respect the one nearest at hand may be considered the best. Under all circumstances the stomach should be rapidly and thoroughly washed out by abundance of mucilaginous fluids, the stomach-pump being used if necessary. The after-effects should be treated like other forms of toxic gastro-enteritis, *i.e.*, by local bloodletting or counter-irritation, demulcent drinks, opiates, etc.

Tests for Corrosive Sublimate. On account of the extreme virulence of this chloride as a poison, the reagents by which it may be detected form a subject of study of the utmost importance, as connected with medico-legal investigations. The best tests for determining its mercurial nature, mentioned in the order of their delicacy, are potassium ferrocyanide, lime water, potassium carbonate, potassium iodide, ammonia, hydrogen sulphide, and stannous chloride. *Potassium ferrocyanide* gives rise to a white precipitate (mercuric ferrocyanide), becoming slowly yellowish, and at length pale blue. *Lime water* throws down a yellow precipitate of hydrated mercuric oxide. *Potassium carbonate* causes a brick-red precipitate of mercuric carbonate. *Potassium iodide* produces a very characteristic pale-scarlet precipitate of mercuric iodide. This precipitate frequently appears at first yellow, especially if the corrosive sublimate be present in minute proportion. *Ammonia* gives rise to a white, flocculent precipitate, the official ammoniated mercury, or white precipitate. *Hydrogen sulphide* occasions a black precipitate of mercuric sulphide; and the same precipitate is thrown down by ammonium sulphydrate. Finally, *tin protochloride* (stannous chloride) causes a grayish-black precipitate (mercury in a finely divided state). Taking the results of Devergie, the relative delicacy of these tests may be expressed numerically as follows: potassium ferrocyanide 1½; lime water 4; potassium carbonate 7; potassium iodide 8; ammonia 36; hydrogen sulphide or ammonium sulphydrate 60; and stannous chloride 80. Wormley (*Micro-Chemistry of Poisons*, 2d ed., p. 348) states that the reaction of stannous chloride is interfered with or entirely prevented by the presence of alkaline chlorates, and also of free nitric acid. He especially commends, however, the copper test, which is as follows: *a bright plate of copper*, immersed in a solution containing corrosive sublimate, is instantly tarnished, and, after the lapse of half an hour, becomes covered with a grayish-white powder. *A polished piece of gold*, moistened with the *clear* mercurial solution, and touched through the liquid with a piece of iron, contracts a white stain. This test, which was proposed by Mr. Sylvester and simplified by Dr. Paris, is conveniently applied by moistening with the suspected solution a gold coin or ring, and touching it through the moistened spot with the point of a penknife. The object of the iron is to form with the gold a simple galvanic circle, which enables the latter metal to precipitate the mer-

cury on its surface. Nearly all the above tests merely prove the presence of mercury. To determine whether the metal is united with chlorine, the mercurial liquid may be precipitated by lime water, and the filtered solution, acidulated with nitric acid, then tested with silver nitrate. If the mercury is in the state of chloride, the filtered solution will be one of calcium chloride, which with silver nitrate will yield a heavy, white precipitate (silver chloride), insoluble in nitric acid, but soluble in ammonia. The silver nitrate may be added directly to the mercurial liquid; and, if it contain corrosive sublimate, silver chloride will fall, but probably mixed with calomel.

By the combined indications of the foregoing tests, corrosive sublimate may be infallibly detected, unless it exists in very minute quantity, associated with organic substances, by which its presence is often greatly obscured. When it exists in organic mixtures, made by boiling the contents or substance of the stomach in distilled water, Dr. Christison recommends that a preliminary trial be made with stannous chloride on a small portion filtered for the purpose. If this causes a grayish-black color, he shakes the mixture, as recommended by Orfila, with a fourth of its bulk of cold ether, which dissolves the corrosive sublimate and rises to the surface. The ethereal solution is then evaporated to dryness, and the dry salt obtained is dissolved in hot water, whereby a pure solution is procured, in which the poison may be readily detected by the ordinary tests. In using ether, however, it must be borne in mind that, as ascertained by M. Mialhe, the presence of a considerable quantity of mercuric oxide, and of a chloride of an alkalifiable metal, prevents the solvent power of ether. If the trial test should produce a light-gray color, the corrosive sublimate is indicated in still less quantity, and Dr. Christison recommends to proceed in the following manner. Treat the unfiltered mixture with stannous chloride, as long as any precipitate is formed, which will have a slate-gray color. Collect, wash, and drain it on a filter, and, having removed it without being dried, boil it, in a glass flask, with a moderately strong solution of caustic potassa, until all the lumps disappear. The alkali will dissolve all animal and vegetable matter; and, on allowing the solution to remain at rest, a heavy grayish-black powder will subside, which consists chiefly of metallic mercury, and in which small globules of the metal may sometimes be seen with the naked eye, or by the aid of a magnifier. Wormley (*loc. cit.*) suggests boiling the organic mixture with water acidulated with hydrochloric acid, and testing the filtered solution with a strip of copper foil. Probably advantage might be derived from the process of dialysis, in separating corrosive sublimate, among other crystallizable substances, from the colloidal matters contained in organic mixtures. (See *Dialysis.*)

HYDRARGYRI CHLORIDUM MITE. U. S. (Br.) Mild Mercurous Chloride. [Calomel. Mild Chloride of Mercury.]

(HĪ-DRÄR′ĢĮ-RĪ ØHLŌ′RĮ-DŬM MĪ′TĒ.)

Hg_2Cl_2; 470·34.* Hg_2Cl_2; 470·2.

Hydrargyri Subchloridum, *Br.*, Mercurous Chloride; Calomelas, Hydrargyrum Chloratum Mite, *P. G.;* Hydrargyri Chloridum, Hydrargyrum Chloratum (Muriaticum), Mercurius Dulcis, Chloruretum Hydrargyrosum; Submuriate of Mercury, Protochloride of Mercury; Subchloride of Mercury; Protochlorure ou Sous-muriate de Mercure, Calomèle, *Fr.;* Quecksilberchlorür, *G.*

"Obtained in the form of powder by the rapid condensation of the vapor of Mercurous Chloride. Mild Mercurous Chloride should be kept in dark amber-colored bottles." *U. S.*

"A salt, Hg_2Cl_2, obtained as a sublimate when a mixture of mercurous sulphate and sodium chloride is heated." *Br.*

Very properly, processes for this compound have been omitted from the Pharmacopœias, as it cannot be made by the pharmacist conveniently. For processes of the U. S. P. 1870 and of the Br. P. 1885, with remarks, see foot-note.†

* The molecular formula and weight are sometimes stated as HgCl; 235·17.

† "Take of Mercury *forty-eight troyounces;* Sulphuric Acid *thirty-six troyounces;* Chloride of Sodium *eighteen troyounces;* Distilled Water *a sufficient quantity.* Boil, by means of a sand-bath, twenty-four troyounces of the Mercury with the Sulphuric Acid, until a dry white mass is left. Rub this, when cold, with the remainder of the Mercury, in an earthenware mortar, until they are thoroughly mixed. Then add the Chloride of Sodium, and, having rubbed it with the other ingredients until globules of Mercury cease to be visible, sublime the mixture into a large chamber so that the sublimate may fall in powder. Wash the sublimed matter with boiling Distilled Water, until the washings afford no precipitate with water of ammonia, and dry it." *U. S.* 1870.

"Take of Persulphate of Mercury *ten ounces* [avoirdupois]; Mercury *seven ounces* [av.]; Chloride of Sodium, dried. *five ounces* [av.]; Boiling Distilled Water *a sufficiency.* Moisten the Persulphate of Mercury with some of the Water, and rub it and the Mercury together until globules are no longer visible; add the Chloride of Sodium, and thoroughly mix the whole by continued trituration. Sublime by a suitable apparatus into a chamber of such size that the Calomel, instead of adhering to its sides as a crystalline crust, shall fall as a fine powder on its floor. Wash

Preparation on the Large Scale. The process for making calomel by means of mercuric sulphate was originally practised at Apothecaries' Hall, London. The proportions taken and the mode of proceeding in that establishment were, according to Mr. Brande, as follows: 50 lbs. of mercury are boiled to dryness with 70 lbs. of sulphuric acid, in a cast-iron vessel; and 62 lbs. of the dry salt formed are triturated with 40½ lbs. of mercury till the globules disappear, and the whole is mixed with 34 lbs. of common salt. The mixture is sublimed from an earthenware retort into an earthenware receiver, and the product is from 95 to 100 lbs. of calomel in mass. This is then ground to an impalpable powder, and washed with a large quantity of distilled water. The object of bringing calomel into a state of minute division is more perfectly accomplished by the method of Mr. Joseph Jewell, of London, improved by M. Ossian Henry. It consists in causing the calomel in vapor to come in contact with steam in a large receiver, whereby it is condensed into an impalpable powder, and perfectly washed from corrosive sublimate in the same operation. Calomel made by this process, sometimes called Jewell's or Howard's *hydrosublimate of mercury*, is free from all suspicion of containing corrosive sublimate, is much finer than when obtained by levigation and elutriation, and possesses more activity as a medicine. This kind of calomel is included in the French Codex under a distinct name (*mercure doux à la vapeur*). M. Soubeiran, of Paris, has perfected a process for obtaining calomel as an impalpable powder, by substituting the agency of cold air for that of steam for the purpose of condensing it; a process which he believes to be precisely the same as that pursued by the English manufacturers, and which produces a calomel equal to the best English. A description of his apparatus may be found in the *Journal de Pharmacie* (3e sér., ii.), and of the English apparatus, as described by F. C. Calvert, in the same journal (3e sér., iii.). Both these papers are copied into the *A. J. P.* (xv.). Calomel may also be prepared in the dry way by taking four parts of corrosive sublimate and rubbing it up in a mortar with three parts of mercury, after moistening the mass with alcohol. The powder is then dried and sublimed in glass flasks. The powder should be dried quickly before sublimation, so as to drive off any trace of uncombined mercury. A comparative examination of English and American calomel was undertaken separately in 1885 by Profs. Bedford and Patch. (See *Proc. A. P. A.*, 1885.) Whilst there was no reason for preferring English calomel, none of the samples exhibited more than traces of mercuric chloride. Prof. Wöhler has proposed to obtain calomel, in the humid way, by precipitating a solution of corrosive sublimate by a stream of sulphurous acid, taking advantage of a reaction first observed by Vogel. Calomel obtained in the humid way, called *precipitated calomel*, was formerly official with the Dublin College, and was adopted in the French Codex. This form of calomel is of doubtful utility; and when obtained by Prof. Wöhler's process it is a crystalline powder, which is unfit for use unless after elaborate levigation and elutriation.

Properties. When in mass, its form and appearance depend on the shape and tempera-

this powder with boiling Distilled Water, until the washings cease to be darkened by a drop of sulphydrate of ammonium. Finally, dry at a temperature not exceeding 212° F. (100° C.)." *Br.* 1885.

The mercurous chloride, according to the view generally received by chemists, consists of two atoms of mercury combined with two of chlorine (some chemists consider it to contain only one atom of each), so that it has relatively only half as much chlorine as corrosive sublimate. In the U. S. process, as in the case of corrosive sublimate, mercuric sulphate is first formed; but, instead of being immediately sublimed with the sodium chloride, it undergoes a preparatory trituration with a quantity of mercury equal to that employed in forming it. This trituration may be conceived to take place between one mol. of mercuric sulphate and one atom of metallic mercury, which are thus converted into one mol. of mercurous sulphate, according to the reaction $HgSO_4 + Hg = Hg_2SO_4$. The one mol. of mercurous sulphate thus formed being heated with two of common salt, the two atoms of chlorine in the latter sublime in union with the two of mercury in the former, and generate one mol. of mercurous chloride, Hg_2Cl_2, while one molecule of sodium sulphate, Na_2SO_4, remains as a residue. It is hence apparent that the residue of this process and of that for corrosive sublimate are the same. The calomel, as sublimed, is liable to contain a little corrosive sublimate; and hence the direction of the U. S. Pharmacopœia of 1870 to wash it with boiling distilled water until ammonia produces no precipitate with the washings. Ammonia occasions a white precipitate (ammoniated mercury) so long as the washings contain corrosive sublimate; and when it ceases to produce this effect the operator may rest satisfied that the whole of the poisonous salt has been removed. According to M. Berthé, calomel in contact with hot water is converted, to a small extent, into corrosive sublimate; and hence he recommends that the portion of water to be tested should be cold when passed through the calomel. The British process is a modification of that of the old Dublin Pharmacopœia, including, like that, no directions for making the mercuric sulphate, because this salt is made by a separate formula, being designated as *persulphate of mercury*. It omits, however, as unnecessary, a partial preliminary sublimation, to test the production of corrosive sublimate, and, immediately after a thorough mixture of the materials, proceeds to the final sublimation. An improvement was to cause the vapors to enter for condensation a chamber of considerable size, so that they might fall in powder, instead of condensing on the sides of the receiver in a crystalline mass. The necessity of pulverizing the calomel is thus avoided. The Br. Pharmacopœia directs the powder to be washed, but, instead of using ammonia as a test of the absence of corrosive sublimate in the washings, directs for the purpose ammonium sulphide, which throws down a black precipitate if corrosive sublimate be present.

ture of the subliming vessel. In this state it is generally in the form of a white, fibrous, crystalline cake, the interior surface of which is often studded with shining transparent crystals, having the shape of quadrangular prisms, and a texture somewhat horny and elastic. When the mass is scratched it yields a yellow streak, which is very characteristic. Its sp. gr. is 7·2. Prof. Patch found in his examination (*Proc. A. P. A.*, 1885, p. 477) the specific gravity of calomel to vary from 6·94 to 7·93, the standard being water at 39° F. The official form of this chloride is that of powder, in which state it is always kept in the shops. The powder has a light buff or ivory color, if obtained by the levigation of sublimed masses; but if condensed at once in the form of an impalpable powder, as is the case with Jewell's calomel and in the official processes, it is perfectly white. To protect it from the action of the light, it should be kept in a dark place, or in bottles painted black or covered with black paper. By the action of the fixed alkalies or alkaline earths it immediately becomes black, in consequence of the formation of mercurous oxide, reducible by heat to the metallic state. The preparation employed under the name of *lotio nigra*, or *black wash*, as a local application to syphilitic ulcers, etc., is made by adding *a drachm* of calomel to *a pint* of lime water. (See *Lotio Nigra, N. F.*) By double decomposition between the calomel and lime, the black suboxide precipitates, and calcium chloride remains in solution, indicated by yielding a copious white precipitate with silver nitrate. The oxide, however, is not pure, but associated with undecomposed calomel. Before being applied, the wash should be well shaken.

"A white, impalpable powder, becoming yellowish-white on being triturated with strong pressure, and showing only small, isolated crystals under a magnifying power of one hundred diameters. It is odorless and tasteless, and permanent in the air. Insoluble in water, alcohol, or ether, and also in cold, dilute acids. When strongly heated, it is wholly volatilized, without melting. In contact with calcium hydrate test-solution, or with solutions of alkali hydrates, or with ammonia water, the salt is blackened. When heated with dried sodium carbonate in a dry glass tube, it yields metallic mercury. If 1 Gm. of the salt be shaken with 10 C.c. of water or alcohol, the respective filtrates should not be affected by hydrogen sulphide test-solution or silver nitrate test-solution (absence of *mercuric chloride*), nor should they leave any residue on evaporation (absence of *other soluble impurities*). On heating a portion of the salt, in a test-tube, with potassium or sodium hydrate test-solution, it should not evolve the odor of ammonia; and if another portion be shaken with acetic acid, the filtrate should not be affected by hydrogen sulphide test-solution, nor by silver nitrate test-solution (distinction from and absence of *ammoniated mercury*)." *U. S.* "A dull-white heavy and nearly tasteless powder, sometimes rendered yellowish by prolonged trituration; insoluble in *water*, *alcohol* (90 per cent.), or *ether*. It affords the reactions characteristic of mercurous salts and of chlorides. Hydrocyanic acid converts it into mercuric salt and a black powder readily yielding metallic mercury. It volatilizes when sufficiently heated, leaving only a trace of fixed residue. Warm *ether* with which it has been shaken leaves, on evaporation, no residue (absence of mercuric chloride). Warmed with *solution of potassium hydroxide* it becomes black and does not evolve ammonia (absence of mercuric-ammonium chloride). When heated with excess of *lime* it should yield 84·4 to 84·9 per cent. of metallic mercury." *Br.*

Tests of Purity and Incompatibles. Calomel, when pure, completely sublimes on the application of heat, a property which detects all fixed impurities, such as calcium carbonate, sulphate, and phosphate, barium sulphate, and lead carbonate. Under the influence of an elevated temperature, especially in the presence of alcohol or water, it gives rise to a small quantity of corrosive sublimate. (*M. Berthé.*) Calomel strikes a black color, free from reddish tinge, by the action of the fixed alkalies; and the black oxide thus produced is brought by heat to the metallic state. The buff color indicates the absence of corrosive sublimate; but whiteness by no means shows the presence of this impurity. Its freedom from the corrosive chloride may be determined by washing a portion of it in warm distilled water, and then testing the water with ammonia, which will cause a white precipitate (ammoniated mercury) should the water have taken up any of the poisonous chloride. (See also the *U. S. P.* 1890 *Tests*, PART III.) An easy method of detecting corrosive sublimate, proposed by M. Bonnewyn, is to put some of the suspected powder upon a well-polished surface of iron, and then moisten it with a drop of alcohol or ether. If the calomel be pure the surface will remain quite unaffected, while it will be blackened by corrosive sublimate if present in the proportion of only one to 50,000. (*Journ. de Pharm. et de Chim.*, 4e sér., ii. 79.) The presence of any soluble chloride whatever in the calomel would be detected by the production of a precipitate with the washing by silver nitrate. Soluble salts of mercury may be detected by rubbing the suspected

calomel with ether on a bright surface of copper, when the metal will become amalgamated and exhibit a white stain. When this test shows impurity, the soluble salt present is probably corrosive sublimate. Calomel containing corrosive sublimate acts violently on the bowels, and, when the impurity has been present in considerable amount, has been known to cause death. Besides being incompatible with the alkalies and alkaline earths, calomel is also decomposed by the alkaline carbonates, soaps, sulphydrates, and, according to some authorities, by iron, lead, and copper. By boiling with the alkaline formiates it is decomposed, and metallic mercury liberated. (H. Rose, *Annal. der Physik und Chem.*, cvi. 500.) According to M. Lebeaux, calomel should not be prescribed with iodine, unless the prescriber intends to give mercuric iodide (red iodide), when the dose must be reduced accordingly. (*Annuaire de Thérap.*, 1857, p. 180.) It should not be given at the same time with nitrohydrochloric acid, for fear of generating corrosive sublimate. One of the authors has been informed of a case in which death, with symptoms of violent gastro-intestinal irritation, followed their joint use. Agreeably to the experiments of M. Deschamps, calomel is decomposed by bitter almonds and by hydrocyanic acid. In the former case corrosive sublimate, mercuric cyanide, and ammonium chloride are formed; in the latter, corrosive sublimate and mercuric cyanide only. Hence this writer considers it very dangerous to associate calomel with bitter almonds or hydrocyanic acid in prescription. This conclusion has been confirmed by M. Mialhe and M. Prenleloup; and more recently it has been shown by Dr. E. Riegel that cherry-laurel water has the power of converting calomel into corrosive sublimate. According to M. Mialhe, calomel is in part converted into corrosive sublimate and metallic mercury by ammonium chloride and by sodium and potassium chlorides, even at the temperature of the body; and hence he believes that the conversion may take place in the primæ viæ. Popular belief coincides with M. Mialhe's views in regard to the power of common salt to increase the activity of calomel.

Medical Properties and Uses. Calomel unites to the general properties of the mercurials those of a purgative and anthelmintic. It is the most valuable of the mercurial preparations. Whether the object is to bring the system under the general influence of mercury, or to produce its alterative action upon the hepatic or other secretory function, calomel, on account both of its certainty and of its mildness, is preferred to all other preparations, with the single exception of the blue pill, which, though less certain, is still milder, and is sometimes preferably employed. When used with the above objects, the tendency to purge which it sometimes evinces, even in very small doses, must be restrained by combining it with opium. As a purgative, calomel owes its chief value to its tendency to act on the liver, the secretory function of which it stimulates. It is usually slow and somewhat uncertain in its cathartic effect, and, though itself but slightly irritating, sometimes occasions severe griping pain with bilious vomiting, attributable to the acrid character of the bile which it causes the liver to secrete. It is peculiarly useful in the commencement of bilious fevers, in hepatitis, jaundice, bilious and painter's colic, dysentery, especially that of tropical climates, and all other affections attended with congestion of the portal system or torpidity of the hepatic function. The difficulty with which it is thrown from the stomach renders it highly useful in some cases of obstinate vomiting, when other remedies are rejected. In the case of children it is peculiarly valuable from the facility of its administration. In the treatment of worms it is often useful as an aid to other remedies, acting probably not only as a purgative, but also as an irritant to the worms, either by its immediate influence or that of the acrid bile which it causes to flow. The slowness and uncertainty of its action, and its liability to salivate if too long retained in the bowels, render it proper either to follow or combine it with other cathartics, in order to insure its purgative effect. When given alone, it should be followed, if it does not operate in six or seven hours, by a dose of castor oil or magnesium citrate. The cathartics with which it is most frequently combined are jalap, rhubarb, aloes, scammony, colocynth, and gamboge. It is often added in small quantities to purgative combinations, with a view to its influence on the liver.

In very large doses, calomel is supposed by some to act directly as a sedative, and with this view has been given in yellow and malignant bilious fevers, violent dysentery, malignant cholera, etc. The quantities which have been administered in such affections, with asserted impunity and even advantage, are almost incredible. A common dose is one or two scruples, repeated every half-hour, or hour, or less frequently, according to the circumstances of the case. It is unquestionable that the effects obtained from calomel are not at all proportionate to the size of the dose. This is evidently due to the peculiarities of its absorption. It seems to be established that it is not, as was at one time supposed, converted in the stomach into corrosive

sublimate, but is precipitated by the alkaline juices of the intestine in the form of black oxide, which black oxide is itself soluble in alkaline liquors and also in fatty matters. A small quantity of calomel coming into the intestines is, therefore, at once converted into black oxide and fully exhausts all the solvent power of the alkaline juices, which may therefore be unable to take up any more rapidly a large than a small amount of the drug. It is possible that in some cases in which minute doses of calomel are given in powdered form, the excessive action of the drug is due to the conversion of part of the calomel into corrosive sublimate.*

Externally applied, calomel is often used as an efficient alterative and desiccant in venereal and other ulcers, herpetic eruptions, etc.

In *syphilis*, calomel vapor-baths once or twice a week are often of service. They may be extemporized by pouring an ounce and a half of water into a dish, putting twenty grains of calomel in it, and heating by means of a spirit-lamp, the patient being seated on a chair over the dish, and surrounded by blankets closely wrapped around the neck, spread out below.

The dose as an alterative, in functional derangement of the liver, is from half a grain to a grain (0·03 to 0·065 Gm.) every night, or every other night, followed in the morning, if the bowels are not opened, by a gentle saline laxative. When the stomach or bowels are very irritable, as in cholera and diarrhœa, from an eighth to a quarter of a grain (0·008 to 0·016 Gm.) may be given every hour or two, so as to amount to one or two grains (0·065 to 0·13 Gm.) in the course of the day. With a view to salivation, the dose is from half a grain to a grain (0·03 to 0·065 Gm.) three or four times a day, to be increased considerably in urgent cases. Sometimes very minute doses, as the twelfth of a grain (0·005 Gm.) or less, given very frequently, so as to amount to the ordinary quantity in twenty-four hours, will operate more effectually as a sialagogue than larger doses. When large doses are given with this view, it is often necessary to combine them with opium. As a purgative, from five to fifteen grains (0·33 to 1 Gm.) or more may be exhibited. The cathartic action is not increased in proportion to the dose, and enormous quantities have been given with impunity. On the other hand, the most effective method of influencing the liver and other intestinal glands is the exhibition of one-quarter to one-half grain doses every hour until the effect is produced or five or six grains have been taken. Even in very small single doses of not more than one, two, or three grains (0·065, 0·13, or 0·20 Gm.), calomel purges some individuals briskly. In these persons, large doses, though they do not proportionally increase the evacuation, often occasion spasmodic pain in the stomach and bowels. For children larger doses are generally required in proportion than for adults. Not less than from two to three grains (0·13–0·20 Gm.) should be given as a purge to a child two or three years old; and this quantity often fails to act, unless assisted by castor oil or some other cathartic. Calomel may be given in pill made with gum arabic and syrup, or in powder mixed with syrup or molasses.

HYDRARGYRI CYANIDUM. U. S. Mercuric Cyanide.

$Hg(CN)_2$; 251·76. (HĬ-DRĂR′ĢĮ-RĪ CĬ-ĂN′Į-DŬM.) $Hg(CN)_2$; 251·7.

Hydrargyri Cyanuretum, *U. S.* 1850; Cyanide of Mercury; Hydrargyrum Cyanatum (Borussicum), Cyanuretum Hydrargyricum, Mercurius Cyanatus vel Borussicus; Cyanuret of Mercury, Bicyanide of Mercury, Prussiate of Mercury; Prussiate ou Cyanure ou Bicyanure de Mercure, *Fr.*; Cyanquecksilber, Quecksilber-Cyanid, *G.*

A process for this preparation is no longer official; that of the U. S. P. 1870 is appended.†

* G. Vulpius has investigated the conditions which favor the formation of corrosive sublimate in calomel mixtures, and reaches the following conclusions:

1. No sublimate forms in the course of twenty-four hours in mixtures of calomel with white sugar, milk sugar, magnesia, magnesium carbonate, and sodium bicarbonate.
2. No such formation takes place in three months in mixtures of calomel with magnesia, magnesium carbonate, and sugar.
3. Minute traces of corrosive sublimate are found at the expiration of the same time in a mixture of calomel, sodium bicarbonate, and sugar of milk.
4. A large quantity of corrosive sublimate forms in the same time in a mixture of calomel, sodium bicarbonate, and cane sugar.
5. Calomel powders containing magnesia or sodium bicarbonate alone will contain corrosive sublimate if digested with water.
6. The formation of corrosive sublimate in mixtures of calomel and alkalies digested in water for a short time is not favored, but, on the contrary, prevented, by the presence of hydrochloric acid in the water, the acid neutralizing, to a certain extent, the alkalies which cause the formation. (*A. J. P.*, July, 1879.)

† *Hydrargyri Cyanidum*, U. S. 1870. "Take of Ferrocyanide of Potassium *five troyounces;* Sulphuric Acid *four troyounces and one hundred and twenty grains;* Red Oxide of Mercury, in fine powder, Water, each, *a sufficient quantity.* Dissolve the Ferrocyanide of Potassium in twenty fluidounces of Water, and add the solution to the Sulphuric Acid, previously diluted with ten fluidounces of Water, and contained in a glass retort. Distil the mixture

The formula of the U. S. P. 1870 is based upon that of Winckler. Hydrocyanic acid is generated by the action of sulphuric acid on potassium ferrocyanide, and, being received in a vessel containing water and a portion of mercuric oxide, reacts with the oxide, according to the reaction $(HCN)_2 + HgO = Hg(CN)_2 + H_2O$, generating, by double decomposition, water, and mercuric cyanide which is held in solution. Sufficient mercuric oxide is not used at first to saturate the whole of the hydrocyanic acid generated, because should there happen to be any excess of the oxide there would be produced on evaporation, instead of the substance wanted, a peculiar salt composed of cyanide and mercuric oxide, which would crystallize in small acicular crystals. Hence a portion of the water still containing uncombined hydrocyanic acid is set aside, to be added to the liquid in which the acid had been completely saturated by the addition of mercuric oxide, and thus at least neutralize any mercuric oxide that might be present in it in excess. A surplus of hydrocyanic acid would be of no disservice, except for the loss of material incurred, as it is evaporated in the subsequent concentration. "Mercuric Cyanide should be kept in well-stoppered, dark amber-colored bottles." *U. S.*

Properties, etc. "Colorless or white, prismatic crystals, odorless, and having a bitter, metallic taste (the salt is exceedingly poisonous). Becoming dark-colored on exposure to light. Soluble, at 15° C. (59° F.), in 12·8 parts of water, and in 15 parts of alcohol; in 3 parts of boiling water, and in 6 parts of boiling alcohol; very sparingly soluble in ether. When slowly heated in a glass tube, the salt decrepitates, and decomposes into metallic mercury and inflammable cyanogen gas, which burns with a purple flame. On further heating, the blackish residue, consisting of paracyanogen with globules of metallic mercury, is wholly dissipated. If 1 part of the salt be gently heated with 1 part of iodine in a dry test-tube, it will afford at first a yellow sublimate which afterwards becomes red, and above this a sublimate of colorless, needle-shaped crystals will be formed. On adding hydrochloric acid to the aqueous solution of the salt, the odor of hydrocyanic acid is evolved. A 5-per-cent. aqueous solution of the salt should be neutral to litmus paper, and should not yield, on the gradual addition of a few drops of potassium iodide test-solution, either a red or a reddish precipitate, soluble in an excess of the precipitant, nor should it yield a white precipitate with silver nitrate test-solution (absence of *mercuric chloride*)." *U. S.* In composition, it is a normal mercuric cyanide, consisting of one atom of the metal and two atoms of cyanogen, its formula being $HgCy_2$, or $Hg(CN)_2$.

Mercuric cyanide is a potent mercurial, which may be substituted for corrosive sublimate, than which it is less irritating, in the treatment of disease. Chibret affirms that as an antiseptic it is even more powerful than the bichloride, and that, unlike the latter substance, it does not attack instruments. Stellden claims extraordinary results in *diphtheria* from its conjoint use as a gargle (1 to 10,000 used every fifteen minutes) and as an internal medicine. Prochorow gives from twenty-five to thirty drops of a one-per-cent. solution hypodermically without causing local irritation, and with great asserted benefit, in chronic syphilis. Dose, internally, from one-sixteenth to one-eighth of a grain (0·004–0·008 Gm.).

HYDRARGYRI IODIDUM FLAVUM. U. S. Yellow Mercurous Iodide.

(HĪ-DRÄR'ĢĬ-RĪ Ī-ÖD'Ĭ-DŬM FLĀ'VŬM.)

Hg_2I_2; 652·66. Hg I; 652·6.

Hydrargyri Iodidum Viride, *Pharm.* 1880; Hydrargyri Iodidum, *U. S.* 1850; Protiodide of Mercury; Yellow (or Green) Iodide of Mercury; Iodide of Mercury; Hydrargyrum Iodatum Flavum, *P. G.;* Hydrargyrum Iodatum, Hydrargyri Iodidum, Ioduretum Hydrargyrosum; Green Iodide of Mercury; Protiodure de Mercure, Iodure mercureux, *Fr.;* Quecksilberjodür, Gelbes Jodquecksilber, *G.*

"Mercury, *fifty grammes* [or 1 ounce av., 334 grains]; Nitric Acid, Potassium Iodide, Distilled Water, Alcohol, each, *a sufficient quantity.* Mix *twenty cubic centimeters* [or 324 minims], each, of Nitric Acid and Distilled Water, and, when the liquid is cold, pour it upon the mercury contained in a small glass flask. Set the mixture aside in a cool and dark place, and agitate it occasionally, until the reaction ceases, and a little mercury still remains undissolved. Separate the crystals of mercurous nitrate, which will have formed, from the mother-liquid, allow them to drain in a glass funnel, and dry them on bibulous paper, in a dark place. When the salt is dry, weigh off *forty grammes* [or 1 ounce av., 180 grains] of it, and dissolve it in

nearly to dryness into a receiver, containing ten fluidounces of Water and three troyounces of Red Oxide of Mercury. Set aside two fluidounces of the distilled liquid, and to the remainder add, with agitation, sufficient Red Oxide to destroy the odor of hydrocyanic acid. Then filter the solution, and, having added the reserved liquid, evaporate the whole in a dark place, in order that crystals may form. Lastly, dry the crystals, and keep them in a well-stopped bottle, protected from the light."

one thousand cubic centimeters [or 33 fluidounces, 6½ fluidrachms] of Distilled Water to which *ten cubic centimeters* [or 162 minims] of Nitric Acid had previously been added. Having prepared a solution of *twenty-four grammes* [or 370 grains] of Potassium Iodide in *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Distilled Water, slowly pour the solution of Potassium Iodide into that of the Mercurous Nitrate, with constant stirring, allow the precipitate to subside, decant the supernatant liquid, and transfer the precipitate, together with the remainder of the liquid, to a filter. When the precipitate has drained, wash it with Distilled Water until the washings no longer have an acid reaction upon litmus paper, and afterwards wash it with Alcohol, as long as the clear, colorless washings give any color with hydrogen sulphide test-solution. Lastly, dry the product in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep it in dark amber-colored vials, with the least possible exposure to light. Instead of weighing off *forty grammes* [or 1 ounce av., 180 grains] of the Mercurous Nitrate as above directed, the whole of the crystallized salt may be taken and the amount of Potassium Iodide, etc., adjusted on the proportions given above." *U. S.*

The Br. Pharmacopœia dropped this salt at its 1885 revision, and the omission has been rather severely criticised.

The process of the U. S. P. 1890 for this salt differs from that formerly official* for green iodide of mercury; it is essentially the process recommended by Edward Soetje (*Proc. A. P. A.*, 1888, p. 167), and is the product of double decomposition between mercurous nitrate and potassium iodide, in solution, *yellow* mercurous iodide and potassium nitrate being formed. This method of making mercurous iodide has long been known, but the disadvantage heretofore has been that some mercuric iodide was formed, which contaminated the product; in the present official product, alcohol is used to wash out all traces of the red mercuric iodide, hydrogen sulphide being used to test the washings. Several other methods of making mercurous iodide have been proposed. M. Roland Seeger suggests double decomposition between mercurous acetate and potassium iodide. (*A. J. P.*, 1859, p. 204.) M. Boutigny proposes to decompose calomel by potassium iodide, and gives the following formula. Twenty-nine drachms of calomel are mixed with twenty drachms of pulverized potassium iodide in a glass mortar, and twelve ounces of boiling distilled water poured upon the mixture. After cooling the liquid is decanted, and the precipitate washed on a filter with distilled water, and dried in the shade. (See *A. J. P.*, viii. 326.) This process was not successful with Mr. Charles Bullock, when he used the reacting ingredients in quantities six times those recommended by M. Boutigny. Mr. John Canavan, of New York, ascribes the failure to insufficient trituration, which, to insure complete reaction, must be long continued. If the reaction be imperfect, the water washes away not only potassium chloride, but also potassium iodide, holding in solution a part of the mercurous iodide formed, which is ultimately decomposed into mercuric iodide and metallic mercury. The experiments of Prof. Maisch tend to confirm this view. He further found that a boiling temperature enables potassium chloride to decompose the mercurous iodide perceptibly, and infers that the use of cold water would give a purer product. He therefore concludes that the process of Boutigny cannot be depended upon for giving a pure mercurous iodide. As prepared by the U. S. formula of 1880, it was liable to contain a little mercuric iodide; but this is obviated in the present edition by the direction to wash it, near the close of the operation, with alcohol. It is known to be free from mercuric iodide when the alcoholic washings produce no cloudiness with water, and no color with hydrogen sulphide solution. According to Mr. F. R. Williams, a boiling solution of common salt is much more efficacious as well as much more economical than alcohol as a solvent for washing out the mercuric from the mercurous iodide. (*P. J. Tr.*, June, 1873, p. 1016; *A. J. P.*, Jan. 1857.) M. P. Yvon has prepared mercurous iodide

* *Hydrargyri Iodidum Viride*, U. S. 1880. "Mercury, *eight parts* [or one ounce av.]; Iodine, *five parts* [or two hundred and seventy-four grains]; Alcohol, *a sufficient quantity*. Pour about *three parts* [or half a fluidounce] of Alcohol into a mortar containing the Mercury, add the Iodine in several, successive portions, and triturate the mixture, adding sufficient Alcohol from time to time to keep the mass constantly moist, and taking care that it shall neither become too hot, nor be exposed to light during the various steps of the process. Continue the trituration until all globules of Mercury have disappeared and the mixture has become nearly dry and has acquired a greenish-yellow color. Then add sufficient Alcohol to reduce the whole to a thin paste, pour this into a bottle, let it stand for several days, and then wash the Iodide twice with about *fifty parts* [or half a pint] of Alcohol each time, and decant the washings. Transfer the Iodide to a filter and continue washing with Alcohol until the washings are no longer affected by hydrosulphuric acid. Lastly, dry the product in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stopped bottles, protected from light." *U. S.* This process for forming the mercurous iodide is a case of simple combination, the alcohol facilitating the union by dissolving the iodine.

by subliming iodine with an excess of mercury, and subsequently washing it with dilute nitric acid. (*Journ. de Pharm.*, 4e sér., xviii. p. 167.) Mr. George A. Haffa precipitates a solution of mercurous nitrate with potassium iodide, and obtains mercurous iodide of a yellow or green color according to the density of the solution. The solution of mercurous nitrate is prepared by acting upon 15,000 grs. of mercury with a cold mixture of nitric acid (6000 grs.) and water (4000 grs.), placing the vessel in cold water, and stirring the contents constantly until the reaction has entirely ceased; the white crystalline mass, without being separated from the excess of metallic mercury, is then dissolved in water acidulated with nitric acid (1 oz. to the gallon) until the solution measures four pints. For preparing *green mercurous iodide*, six ounces of a solution of mercurous nitrate are mixed with six pints of water, and there is added in a continuous stream, and with constant stirring, a solution of potassium iodide (3 oz. in 54 oz. of water); the precipitate is washed with water, and dried without the aid of heat. *Yellow mercurous iodide* is prepared in the same manner, except that two ounces of solution of mercurous nitrate diluted with water (8 pints) are used with a solution of potassium iodide (1 oz. in 4 pints of water). This salt darkens much more quickly when exposed to the light than that made by the pharmacopœial process. (*A. J. P.*, 1886.) Stoman practically confirms these results. (*Ber. d. Deutsch. Chem. Ges.*, 1887; see, also, *Pharm. Era*, 1888.) From experiments by Mr. C. H. Wood, it appears that the green iodide is a mixture of red iodide and metallic mercury. By continuing the trituration, the powders become more and more yellow, and at length have only a tinge of green. He infers that pure mercurous iodide is yellow, and that the green color is owing to an admixture of the blue of the mercury with the yellow of the mercurous iodide.* (*P. J. Tr.*, 1868.) Flückiger (*Pharmaceutische Chemie*, 2d ed., 1888) agrees with this view, and says that by slow sublimation, at a very gentle heat, the true mercurous iodide can be obtained in small transparent yellow crystals of the quadratic system which are related to the forms of calomel. (See *Journ. de Pharm. et de Chim.*, 1894, 67.)

Properties. "A bright yellow, amorphous powder, odorless and tasteless. By exposure to light it becomes darker, in proportion as it undergoes decomposition into metallic mercury and mercuric iodide. Almost insoluble in water, and wholly insoluble in alcohol or ether. When slowly and moderately heated, it assumes at first an orange and then a red color, becoming yellow again on cooling. When quickly and strongly heated, it is at first partially decomposed into mercury and mercuric iodide, and finally is completely volatilized. When it is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved. In contact with a solution of potassium iodide, the salt is decomposed into mercuric iodide, which dissolves, leaving a residue of metallic mercury. If 0·5 Gm. of the salt be shaken with 10 C.c. of alcohol, a portion of the filtrate should be scarcely affected by hydrogen sulphide test-solution, nor should it produce more than a very faint, transient opalescence when dropped into water; and if 5 C.c. of the filtrate be evaporated from a white porcelain surface, not more than a very faint, red stain should remain (absence of more than traces of *mercuric iodide*)." *U. S.* Its sp. gr. is 7·75. If quickly and cautiously heated, it sublimes in red crystals, which afterwards become yellow. "Gradually heated in a test-tube, it yields a yellow sublimate, which, upon friction, or after cooling, becomes red, while globules of metallic mercury are left in the bottom of the tube." *Br.* 1867. It is generally considered to be composed of two atoms of mercury united with two atoms of iodine, Hg_2I_2, 399·6 + 253·06 = 652·66, although some chemists make its formula HgI, consisting of one atom of mercury 199·8, and one of iodine 126·53 = 326·33. (See *Chem. News*, 1896, 12, 95, 306.)

Medical Properties and Uses. Mercurous iodide is used in advanced *syphilis*. The dose is half a grain (0·033 Gm.) daily, gradually increased to two grains (0.13 Gm.). It should never be given at the same time with potassium iodide, which converts it immediately into mercuric iodide and metallic mercury. (Mialhe, *Journ. de Pharm.*, 3e sér., ix. 36.)

* Patrouillard recommends Dublanc's process, which consists in triturating together a mixture of mercuric (red) iodide and of metallic mercury, in the following proportions: mercuric iodide 227 parts; mercury 100 parts. The mercuric iodide may easily be obtained of absolute purity and in a state of perfect dryness; besides, during the trituration there is no risk of loss by volatilization. The mixture should merely be moistened with alcohol of eighty per cent., so as to form a thin paste, and well triturated; the reaction takes place in a very short time, and the product is of a dark greenish-yellow color. By way of precaution, it should be washed with boiling alcohol. (*Rép. de Pharm.*, 1877, 549; *N. R.*, Nov. 1877.)

HYDRARGYRI IODIDUM RUBRUM. U. S., Br. Red Mercuric Iodide.

[Biniodide of Mercury. Red Iodide of Mercury.]

HgI_2; 452·86. (HĬ-DRĂR'ĢĬ-RĪ Ī-ŌD'Ĭ-DŬM RŪ'BRŬM.) HgI_2; 452·9.

"Precipitated Mercuric Iodide, HgI_2, formed by the interaction of mercuric chloride and potassium iodide." *Br.*

Mercuric Iodide, *Br.;* Hydrargyrum Biiodatum Rubrum, *P. G.;* Mercurius Iodatus Ruber, Deutoioduretum Hydrargyri, Ioduretum Hydrargyricum; Deuto-iodure (Bi-iodure) de Mercure, Iodure mercurique, *Fr.;* Quecksilberjodid, Rothes Jodquecksilber, *G.*

"Corrosive Mercuric Chloride, *forty grammes* [or 1 ounce av., 180 grains]; Potassium Iodide, *fifty grammes* [or 1 ounce av., 334 grains]; Distilled Water, *a sufficient quantity.* Dissolve the Corrosive Mercuric Chloride and the Potassium Iodide, each, in *eight hundred cubic centimeters* [or 27 fluidounces, 24 minims] of Distilled Water, and filter the solutions separately. Pour both solutions, simultaneously and in a thin stream, under constant and very active stirring, into *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of Distilled Water. When the precipitate has subsided, decant the supernatant liquid, collect the precipitate on a filter, and wash it with cold Distilled Water, until the washings give not more than a slight opalescence with silver nitrate test-solution. Finally, dry it in a dark place, between sheets of bibulous paper, at a temperature not exceeding 40° C. (104° F.). Keep the product in well-stoppered bottles, protected from light." *U. S.*

In the above process for forming mercuric iodide a double decomposition takes place between corrosive sublimate and potassium iodide, resulting in the formation of potassium chloride which remains in solution, and mercuric iodide which precipitates. The precipitate is soluble in the reacting salts, and hence a loss of part of it is incurred by an excess of either. It is best, however, to have a slight excess of the potassium iodide, which is furnished by the proportion taken in the formula, as then the decomposition of the whole of the corrosive sublimate is insured, and any contamination of the mercuric iodide by it prevented; loss by solution in the supernatant liquid is largely prevented by the improvement introduced in the U. S. 1890 process, whereby separate solutions are poured simultaneously into a large volume of water. The late process of the Edinburgh College consisted in a combination of the ingredients by trituration in due proportion with the aid of alcohol; but after the red powder was obtained it was treated with a boiling solution of common salt, which dissolved the mercuric iodide to the exclusion of any contaminating mercurous iodide; and the solution thus obtained, on cooling, deposited the pure mercuric salt in crystals. Mr. F. R. Williams states that in the manufacture of the red iodide on a large scale the amount of water required by the official processes is very troublesome. He remedies it by using ammonium chloride, so as to get a very concentrated solution of corrosive sublimate, which he adds to a concentrated solution of the iodide. The addition of the ammonium chloride does not interfere with the reaction, but is of material service in assisting in the solution of the corrosive sublimate. (*P. J. Tr.*, June, 1873.)

Dr. Chas. L. Mitchell has improved upon the process of Williams; see foot-note.*

Properties. As obtained by the late Edinburgh process, it is in splendid crimson acicular crystals. Köhler has found, however, that it crystallizes better from boiling hydrochloric acid. (*Ber. der Deutsch. Chem. Ges.*, 1879, p. 608.) It also crystallizes well from hot saturated solutions in acetone, glacial acetic acid, absolute alcohol, amyl alcohol, and nitric acid of 1·2 sp. gr. When heated the mass becomes yellow at about 150° C. (302° F.), melting at 254° C. (489·2° F.) to a blood-red liquid, and sublimes at 349° C. in yellow rhombic scales, which become red on cooling. Mercuric iodide is a dimorphous substance, having a different crystalline form in its red and yellow states. According to Schiff, it is only in its yellow form that it is soluble in alcohol; and hence it is that, when separated by water from its alcoholic solution, it falls in this condition. (*Ann. der Chem. und Pharm.*, cix. 371.) It forms definite compounds with the iodides of the alkali metals. The compound formed with potassium iodide has been used as a medicine. (See *Potassium Iodohydrargyrate*, in PART II.) "When digested

* *Hydrargyri Iodidum Rubrum, Mitchell's Process.* Mercury, 1000 grs.; Nitric Acid, 1700 grs.; Potassium Iodide, 1662 grs. or q. s.; Distilled Water, q. s. (Instead of the mercury and nitric acid, ℥v ℥i ℈ii of Liq. Hydrarg. Nit. can be used.) Dissolve the mercury in the nitric acid by the aid of a little heat (in large quantities this is not necessary, as the reaction between the acid and the mercury generates sufficient heat), and dilute with an equal bulk of water. Then add the potassium iodide, dissolved in eight fluidounces of water, until no further precipitation ensues, being careful towards the last to add the solution very gradually, so as to avoid dissolving the mercuric iodide in an excess of the liquid. Collect the precipitate on a filter, wash well with distilled water, drain and dry. (*A. J. P.*, 1876, 116.)

with solution of soda it assumes a reddish-brown color, and the fluid, cleared by filtration and mixed with solution of starch, gives a blue precipitate on being acidulated with nitric acid," showing that it is an iodide. Mercuric iodide consists of one atom of mercury 199·8, and two atoms of iodine 253·06 = 452·86, and its formula is HgI_2. It combines with mercurous iodide, so as to form a yellow *sesqui-iodide*, represented by the formula $HgI + HgI_2$, or Hg_2I_3.

"A scarlet-red, amorphous powder, odorless and tasteless; permanent in the air. Almost insoluble in water, but soluble in 130 parts of alcohol at 15° C. (59° F.), and in 15 parts of boiling alcohol;* also soluble in a solution of potassium iodide, or of mercuric chloride, and in a solution of sodium hyposulphite. When heated to about 150° C. (302° F.), the salt becomes yellow, but again assumes a red color on cooling; at 238° C. (400·4° F.) it fuses to a dark yellow liquid, which, on cooling, forms a yellow, crystalline mass, and, at higher temperatures, volatilizes without decomposition, leaving no residue. On heating the salt with potassium or sodium hydrate test-solution, and adding a little sugar of milk, metallic mercury is precipitated. When it is heated with sulphuric acid and a little manganese dioxide, vapor of iodine is evolved. If the salt be dissolved in hot alcohol, the solution, after cooling, should be colorless; and when this solution is diluted with an equal volume of water, it should not redden blue litmus paper (absence of *mercuric chloride*). If about 0·5 Gm. of the salt be shaken with 10 C.c. of water, the filtered liquid should not become more than very slightly colored by hydrogen sulphide test-solution, nor give more than a slight opalescence with silver nitrate test-solution (limit of *soluble chlorides* or *iodides*)." *U. S.* "A crystalline powder of a vermilion color, becoming yellow when a film of it spread on a sheet of paper is gently heated over a lamp. It is almost insoluble in *water*, dissolves sparingly in *alcohol* (90 per cent.), but freely and entirely in *ether* (absence of mercurous iodide), or in *solution of potassium iodide*. It affords the reactions characteristic of mercuric compounds and of iodides. It volatilizes at a temperature under redness, leaving not more than a trace of fixed matter. When heated with excess of *copper* it should yield 43·5 to 44 per cent. of metallic mercury." *Br.*

Medical Properties and Uses. Mercuric iodide is a powerful irritant poison. It has been used in similar diseases with the mercurous iodide, namely, in *scrofula* and *syphilis*, but is much more active. It is especially valuable in old, obstinate cases of syphilis, as in syphilitic rheumatic pains and diseases of the bones, thickening of the dura mater, etc. There seems to be in these cases no practical difference between its action and that of corrosive sublimate, although sometimes it is better borne by the stomach than is the latter preparation. The dose is one-sixteenth of a grain (0·004 Gm.), gradually increased to one-fourth of a grain (0·016 Gm.), given in pill. It is sometimes administered in water with potassium iodide so as to make a solution of potassio-mercuric iodide.† M. Cazenave considers mercuric iodide to be the best topical application in *lupus*. He applies it in thin layers, every six or eight days, to small portions of the ulcerated surface at a time, in the form of a caustic ointment, made of equal parts of the iodide, oil, and lard. The application produces severe pain, and gives rise to a sharp inflammation, which soon terminates, leaving the ulcer in an improved condition, with a tendency to cicatrize smoothly and on a level with the surrounding skin. (*Ann. de Thérap.*, 1852, 175.) A solution of mercuric iodide in olive oil (1 in 5000), for external application, has been prepared by Delacour. (*Journ. de Pharm. et de Chim.*, 1893, 603.)

HYDRARGYRI OXIDUM FLAVUM. U. S., Br. Yellow Mercuric Oxide.

Hg O; 215·76. (HĬ-DRĂR'ĢĬ-RĪ ŎX'Ĭ-DŬM FLĀ'VŬM.) Hg O; 215·7.

"Precipitated Mercuric Oxide, HgO, obtained by the interaction of mercuric chloride and sodium hydroxide." *Br.*

* Bourgoin has given solubilities different from these. (See *Amer. Drug.*, 1885, p. 97.) For paper on solubility in fatty bodies, by C. Méhu, see *P. J. Tr.*, 1885, p. 327.)

† A syrup has been largely used in the French hospitals and in this country which has received the name of *Sirop Gibert.* It is made by dissolving *three grains* of *mercuric iodide* and *one hundred and two grains* of *potassium iodide* in *three fluidrachms* of water, filtering, and adding sufficient simple syrup to make *ten fluidounces.* Each tablespoonful contains about one-seventh of a grain of mercuric iodide and five grains of potassium iodide.

Corrosive Mercuric Chloride in *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of warm Distilled Water, and filter the solution. Dissolve the Soda (which should contain 90 per cent. of sodium hydrate) in *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of cold Distilled Water, and into this solution pour gradually, and with constant stirring, the solution of Corrosive Mercuric Chloride. Allow the mixture to stand for an hour at a temperature of about 30° C. (86° F.), stirring frequently. Then decant the supernatant, clear liquid from the precipitate, and wash the latter repeatedly by the affusion and decantation of Distilled Water, using *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms] of Water each time. Collect the precipitate on a strainer, and continue the washing with warm Distilled Water, until a small portion of the washings, when poured on a little mercuric chloride test-solution, no longer produces a yellowish turbidity at the line of contact of the two liquids. Then allow the precipitate to drain, and dry it between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.). Keep the product in well-stoppered bottles, protected from light." *U. S.*

The process adopted for this preparation is that of Dr. Hoffmann. The United States Pharmacopœia directs the alkaline solution in excess, and the addition of the corrosive sublimate to the alkali. Both these points are important, for if the corrosive sublimate be in excess, brown oxychloride will be formed towards the last of the decomposition; and when the alkali is added to the solution of corrosive sublimate, the same compound will be formed from the first, and is with difficulty decomposed by an excess of alkali. The solution of soda should be as free as possible from carbonate, to prevent the formation of brown mercuric carbonate. The mercuric chloride is precipitated by the alkalies, potassium or sodium chloride being left in solution. The object of the subsequent washing is to remove the potassium chloride and the excess of the alkali.* The process has been improved through the use of a freshly made solution of soda: the official solution of potassa used in the U. S. P. 1880 process almost invariably contained potassium carbonate, except when it was freshly made, and the presence of carbonate gives the mercuric oxide a reddish-brown tint which is very objectionable.

Properties. The official mercuric oxide is of a yellow color similar to that of the yolk of egg, and is a completely amorphous powder, exhibiting no evidence of crystalline particles even under the microscope. Yellow mercuric oxide differs only from the red by being amorphous and in a much more minute state of division; the red oxide by trituration acquiring an orange and finally a yellow color. In consequence of its different state of aggregation, it presents some peculiarities in its chemical relations, and is much more quickly acted on by reagents than is the red oxide. Thus, oxalic acid, which acts on the red oxide only with the aid of heat, immediately combines with the yellow oxide at ordinary temperatures, producing the white oxalate; and while the latter oxide, in contact with chlorine, gives up oxygen to that element, forming hypochlorous acid and corrosive sublimate, the former exercises scarcely any influence on the gas at common temperatures. It is described in the U. S. Pharmacopœia as "a light orange-yellow, amorphous, heavy, impalpable powder, odorless, and having a somewhat metallic taste; permanent in the air, but turning darker on exposure to light. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When moderately heated, the Oxide assumes a red color. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no residue. If 0·5 Gm. of the Oxide be digested on a water-bath, for fifteen minutes, with a solution of 1 Gm. of oxalic acid in 10 C.c. of water, it will be converted into white mercuric oxalate (distinction from *red mercuric oxide*). On dissolving 1 Gm. of the Oxide in 100 C.c. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate test-solution (limit of *chloride*)." *U. S.* "A yellow powder yielding nothing to *water*, but being readily dissolved by *hydrochloric acid*, the solution affording the reactions characteristic of mercuric salts. Gently heated it assumes a red color. Heated to incipient redness it is resolved into oxygen and the vapor of mercury, leaving only an insignificant amount of fixed residue; the proportion of metallic mercury obtained being 92 to 92·5 per cent." *Br.* I. Comere explains in a paper in *Répert.*

* Dr. Charles L. Mitchell proposes an improvement on the official process, which avoids the use of large vessels when it is made on a large scale. He takes of solution of mercuric nitrate (prepared by dissolving mercury in an excess of nitric acid), any convenient quantity; solution of soda, U. S. P., a sufficient quantity. The solution of mercuric nitrate is diluted with an equal bulk of water, and solution of soda added until in slight excess. The yellow precipitate is collected, washed well, and dried.

de Pharm., 1881, 199, the various conditions and modifications in the process necessary to make the oxide vary in color. (*N. R.*, 1882, 149.)

Medical Properties. The attention which has been recently paid to the yellow oxide is owing to its peculiar applicability to the local treatment of diseases of the eye, in consequence of its amorphous character. Mr. B. Squire, of England, was the first to notice publicly this use of the oxide (*P. J. Tr.*, 2d ser., vi. 512). At present the yellow oxide is very largely used by oculists throughout the world. The red oxide, however carefully it may be triturated, even though in a perfectly impalpable state, still shows under the microscope crystalline particles, which in contact with the conjunctiva cause more or less irritation; and it can, therefore, be readily understood that, in the ordinary mode of preparing it for use as an ointment, it may sometimes be productive of serious annoyance. From this objection the yellow oxide is exempt.

"Red Mercuric Oxide should be kept in well-stoppered bottles, protected from light." *U. S.*

Neither Pharmacopœia gives at present an official process for this oxide. For former processes, see below.*

The preparation is still frequently called by its older name, *red precipitate*. The name of *red mercuric oxide* is appropriate, as mercuric nitrate exists in it merely as an accidental impurity; and there is no occasion to distinguish the preparation from the oxide obtained by calcining mercury, the latter not being official, and perhaps never employed.

In the preparation of this mercurial, various circumstances influence the nature of the product, and must be attended to, if we desire to procure the oxide with that fine bright orange-red color, and shining scaly appearance, usually considered desirable. Among these circumstances is the condition of the mercuric nitrate submitted to calcination. According to Gay-Lussac, it should be employed in the form of small crystalline grains. If previously pulverized, as directed in the official processes, it will yield an orange-yellow powder; if it be in the state of large and dense crystals, the oxide will have a deep orange color. Care must also be taken that the mercury and acid be free from impurities. It is highly important that sufficient nitric acid be employed fully to saturate the mercury. M. Payssé, who paid great attention to the manufacture of red precipitate, recommended 70 parts of nitric acid from 34° to 38° Baumé, to 50 parts of mercury. This, however, is an excess of acid. We have been told by a skilful practical chemist of Philadelphia that he has found, by repeated experiment, 7 parts of nitric acid of 35° Baumé to be sufficient fully to saturate 6 parts of mercury. Less will not answer, and more will be useless. It is not necessary that the salt should be removed from the vessel in which it is formed; and it is even asserted that the product is always more beautiful when the calcination is performed in the same vessel. A matrass may be used with a large flat bottom, so that an extended surface may be exposed and all parts heated equally. The metal and acid having been introduced, the matrass should be placed in a sand-bath, and covered with

* "Take of Mercury *thirty-six troyounces*; Nitric Acid *twenty-four troyounces*; Water *two pints*. Dissolve the Mercury, with the aid of a gentle heat, in the Acid and Water previously mixed, and evaporate to dryness. Rub the dry mass into powder, and heat it in a very shallow vessel until red vapors cease to rise." *U. S.* 1870. "Take of Mercury, by weight, *eight ounces* [avoirdupois]; Nitric Acid *four fluidounces and a half* [Imperial measure]; Water *two fluidounces* [Imp. meas.]. Dissolve half the Mercury in the Nitric Acid diluted with the Water, evaporate the solution to dryness, and with the dry salt thus obtained, triturate the remainder of the Mercury until the two are uniformly blended together. Heat the mixture in a porcelain dish, with repeated stirring, until acid vapors cease to be evolved." *Br.* 1885.

In this process the mercury is dissolved by the nitric acid, forming either mercuric nitrate, or a mixture of this with mercurous nitrate. The resulting mass when exposed to a strong heat is decomposed, giving out red nitrous fumes, and assuming successively a yellow, an orange, and a brilliant purple-red color, which becomes orange-red on cooling. These changes are owing to the gradual separation and decomposition of the nitric acid, by the oxygen of which the mercurous oxide, if any be present, is converted into mercuric oxide, while nitrogen dioxide gas escapes, and becomes nitrogen tetroxide on contact with the air. The mercuric oxide is left behind, but in general not quite free from the nitrate, which cannot be wholly decomposed by heat without endangering the decomposition of the oxide itself, and the volatilization of the metal.

sand up to the neck. The solution of the mercury should be favored by a gentle heat, which should afterwards be gradually increased till red vapors appear, then maintained as equably as possible till these vapors cease, and at last slightly elevated till oxygen gas begins to escape. This may be known by the increased brilliancy with which a taper will burn if placed in the mouth of the matrass, or by its rekindling if partially extinguished. Too high a temperature must be carefully avoided, as it decomposes the oxide and volatilizes the mercury. At the close of the operation, the mouth of the vessel should be stopped, and the heat gradually diminished, the matrass being still allowed to remain in the sand-bath. These last precautions are said to be essential to the fine red color of the preparation. It is best to operate upon a large quantity of materials, as the heat may be thus more uniformly maintained. The former direction of the Br. Ph., to rub a portion of mercury with the nitrate before decomposing it, renders the process more economical; as the nitric acid, which would otherwise be dissipated, is thus employed in oxidizing an additional quantity of the metal. As the process is ordinarily conducted in laboratories, the mercuric nitrate is decomposed in shallow earthen vessels, several of which are placed upon a bed of sand, in the chamber of an oven or furnace, provided with a flue for the escape of the vapors. Each vessel may conveniently contain ten pounds of the nitrate. There is always loss in the operation thus conducted.*

Properties, etc. Red precipitate, well prepared, has a brilliant red color, with a shade of orange, a shining scaly appearance, and an acrid taste. It is very slightly soluble in water, of which Dr. Barker found 1000 parts to take up 0·62 of the oxide. Dr. Christison found 1 part of the oxide to be dissolved by about 7000 parts of boiling water, and the solution to give a black precipitate with hydrogen sulphide. Tannic acid precipitates metallic mercury from an aqueous solution of the oxide, especially when heated. (Bullock, *Proc. A. P. A.*, 1858, p. 306.) It is insoluble in cold alcohol and ether. (*Ibid.*) Nitric and hydrochloric acids dissolve it without effervescence. "Heavy, orange-red, crystalline scales, or a crystalline powder, becoming more yellow the finer it is divided, odorless, and having a somewhat metallic taste; permanent in the air. Almost insoluble in water, insoluble in alcohol, but readily and completely soluble in diluted hydrochloric or nitric acid, forming colorless solutions. When heated to about 400° C. (752° F.), it becomes dark violet or almost black, but assumes its original color on cooling. At a red heat it is completely decomposed into oxygen and metallic mercury, and is finally volatilized, leaving no residue. If 0·5 Gm. of the Oxide be digested, on a water-bath, with a solution of 1 Gm. of oxalic acid in 10 C.c. of water, it will not change color within two hours (distinction from *yellow mercuric oxide*). If a little of the Oxide be strongly heated in a test-tube, the vapors should not redden moistened blue litmus paper (absence of *nitrate*). On dissolving 1 Gm. of the Oxide in 100 C.c. of diluted nitric acid, the resulting solution should be clear, and should not afford more than a slight opalescence with silver nitrate test-solution (limit of *chloride*)." *U. S.* "Orange-red crystalline scales or powder answering to the tests given under 'Hydrargyri Oxidum Flavum.' When gently heated it becomes dark violet, but resumes its orange-red color on cooling. When heated in a dry test-tube it should not evolve orange fumes (absence of nitrates)." *Br.* It is essentially mercuric oxide, consisting of one atom of the metal 199·8, and one of oxygen 15·96 = 215·76; but in its ordinary state it always contains a minute proportion of nitric acid, probably in the state of subnitrate. According to Brande, when rubbed and washed with a solution of potassa, edulcorated with distilled water, and carefully dried, it may be regarded as nearly pure mercuric oxide. It is said to be sometimes adulterated with brickdust, red lead, etc.; but these may be readily detected, as mercuric oxide is wholly dissipated if thrown upon red-hot iron. The disengagement of red vapors when it is heated indicates the presence of mercuric nitrate. The same or some other saline impurity would be indicated should water, in which the oxide has been boiled, afford a precipitate with lime water.

Medical Properties and Uses. This preparation is too harsh and irregular in its operation for internal use, but is still employed externally as a stimulant and escharotic in the state either of powder or of ointment, although to a great extent supplanted by the yellow oxide. The powder is sprinkled on the surface of *chancres*, and *indolent*, *flabby*, or *fungous ulcers*. The powder should be finely levigated.†

* For a process for *Hydrargyrum præcipitatum per se, precipitate per se,* or *calcined mercury,* all practically identical with red mercuric oxide, see *U. S. D.*, 17th ed., 704.

† *Hydrargyri Oxidum Nigrum.* U. S. 1850. *Black Mercurous Oxide.* This preparation has been dropped from both Pharmacopœias, and is now very rarely used. For a full account of its preparation, uses, and properties, see *U. S. D.*, 14th ed., 1256.

HYDRARGYRI SUBSULPHAS FLAVUS. U. S. Yellow Mercuric Subsulphate. [Basic Mercuric Sulphate. Turpeth Mineral.]

$Hg(HgO)_2SO_4$; 727·14. (HĬ-DRĂR'ĢĬ-RĪ SŬB-SŬL'PHĂS FLĀ'VŬS.) $Hg(HgO)_2SO_4$; 727·1.

Hydrargyri Sulphas Flava, *U. S.* 1870; Hydrargyri Subsulphas, Mercurius Emeticus Flavus, Sulphas Hydrargyricus Flavus, Hydrargyrum Sulphuricum Flavum, Turpethum Minerale; Sulfate jaune de Mercure, Turbith minéral, Sulfate trimercurique, *Fr.*; Basischwefelsaures Quecksilberoxyd, Mineralischer Turpeth, *G.*

"Mercury, *one hundred grammes* [or 3 ounces av., 230 grains]; Sulphuric Acid, *thirty cubic centimeters* [or 1 fluidounce, 7 minims]; Nitric Acid, *twenty-five cubic centimeters* [or 405 minims]; Distilled Water, *a sufficient quantity*. Upon the Mercury, contained in a capacious flask, pour the Sulphuric Acid, previously mixed with *fifteen cubic centimeters* [or 243 minims] of Distilled Water, then add, very gradually, the Nitric Acid, previously mixed with *twenty-five cubic centimeters* [or 405 minims] of Distilled Water, and digest at a gentle heat until reddish fumes are no longer given off. Transfer the mixture to a porcelain capsule, and heat it on a sand-bath, under a hood or in the open air, with frequent stirring, until a dry, white mass remains. Reduce this to a fine powder, and add it in small portions at a time, with constant stirring, to *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of boiling Distilled Water. When all has been added, continue the boiling for ten minutes; then allow the mixture to settle, decant the supernatant liquid, transfer the precipitate to a strainer, wash it with warm Distilled Water, until the washings no longer have an acid reaction, and dry it in a moderately warm place. Keep the product in well-stoppered bottles, protected from light." *U. S.*

By referring to the articles on corrosive sublimate and calomel, it will be found that the peculiar salt which is generated by boiling sulphuric acid with mercury to dryness is directed to be made as the first step for obtaining these chlorides; and here the same salt is again directed to be formed in preparing turpeth mineral. The nitric acid assists in the process by hastening the formation of the sulphate. We have already stated that this salt is normal mercuric sulphate. When thrown into boiling or even warm water it is instantly decomposed, and an insoluble salt is precipitated, which is the turpeth mineral. Its composition is Hg_3SO_6, or, more clearly expressed, $HgSO_4 + 2HgO$; that is, a compound of one mol. of mercuric sulphate and two mols. of mercuric oxide.

Properties, etc. Yellow mercuric subsulphate is "a heavy, lemon-yellow powder, odorless and almost tasteless; permanent in the air. Soluble in about 2000 parts of water at 15° C. (59° F.), and in 600 parts of boiling water; insoluble in alcohol; readily soluble in nitric or hydrochloric acid. When heated, the salt turns red, becoming yellow again on cooling. At a red heat it is volatilized, evolving vapors of mercury and of sulphur dioxide, and leaving no residue. A solution of the salt in nitric or hydrochloric acid, diluted with water, gives with potassium iodide test-solution a red precipitate, and with barium chloride test-solution a white one. The salt should be completely soluble in 10 parts of hydrochloric acid (absence of *mercurous salt* or of *lead*)." *U. S.* It was originally called *turpeth* mineral, from its resemblance in color to the root of *Ipomœa turpethum*.

Medical Properties and Uses. Turpeth mineral is alterative, and powerfully emetic and errhine. It operates with great promptness, and sometimes excites ptyalism. Dr. Hubbard, of Maine, recommends it highly as an emetic in *croup*, on the ground of its promptness and certainty, and of its not producing catharsis, or the prostration caused by antimony. This practice has been followed with alleged extraordinarily good results by Dr. Fordyce Barker, of New York, and other practitioners, but is not without danger, since Dr. A. McPhedran reports (*Med. News*, vol. xliii., 1883) a case in which a child five months old was killed by two powders given as emetics at intervals of fifteen minutes. No vomiting ensued, but violent purging came on in the course of a short time, with intense abdominal pain and other symptoms of poisoning resembling those caused by corrosive sublimate. A second similar case occurred in the practice of Dr. Cameron, of Toronto, Canada. The dose for a child two years old is two or three grains (0·13 or 0·20 Gm.), repeated in fifteen minutes if it should not operate. The dose as an alterative is from a quarter to half a grain (0·016–0·03 Gm.); as an emetic, from two to five grains (0·13–0·33 Gm.). When employed as an errhine, one grain (0·065 Gm.) may be mixed with five grains (0·33 Gm.) of starch or powdered liquorice root. One drachm taken internally has caused death in a boy sixteen years old. (*Lon. Med. Gaz.*, 1847.)

HYDRARGYRUM. U. S., Br. Mercury. [Quicksilver.]

Hg; 199·8. (HĪ-DRĂR'ĢĬ-RŬM.) **Hg; 199·7.**

"A metal obtained from native mercuric sulphide." *Br.*

Quicksilver; Mercurius Vivus; Argentum Vivum; Mercure, Vif Argent, *Fr.;* Quecksilber, *G.;* Mercurio, *It.;* Azógue, *Sp.* and *Port.*

Mercury is found pure, forming an amalgam with silver, in the form of chloride (native calomel), but most abundantly as the sulphide or native cinnabar. Mines of this metal are found at Almaden in Spain, at Idria in Carniola, in the former duchy of Deux-Ponts, in Belluno, a province of Venetia, in Corsica, in the Philippine Islands and China, near Huancavelica in Peru, near Azogue in Colombia, at Durango in Mexico, and at New Almaden, New Idria, and other localities in Santa Clara County, California, about sixty-six miles from San Francisco. The most ancient mine is that of Almaden in Spain, which was worked before the Christian era. This mine, and the mines of California, are the most productive at the present day; the Spanish mine yielding about three and a quarter millions of pounds, and the California mines about two-thirds of this amount, annually. The ore in all the mines mentioned is cinnabar. The cinnabar from old Almaden is of a dull-red color in mass, of a dull brick-red color when in fine powder, and of the sp. gr. 3·6. That from New Almaden is of a bright-red color, slightly inclining to purple, not so hard as the Spanish ore, of a brilliant vermilion color in powder, and of the sp. gr. 4·4. The California cinnabar is richer in mercury, because purer, than the Spanish; the former yielding about 70 and the latter about 38 per cent. of mercury, according to the analysis of Mr. Adam Bealey. The California mine had been long known to the Indians, but its commercial value was first made known about 1843, by a Mexican, named Castillero, who became its first owner. At present it is in the hands of Americans. Dr. Ruschenberger has detected selenium in California cinnabar. A quicksilver ore has been found in Macon County, Tennessee, where it is said to exist in quantities. According to Mr. E. S. Wayne, it is a talcose rock, and contains mercury in the metallic state, yielding 7·5 per cent. of the metal. (*A. J. P.*, 1868, p. 76.) Mercury has also been found in the island of Borneo, district of Sarawak. (*Chem. News*, Nov. 5, 1869, p. 224.)

Extraction, etc. Mercury is obtained almost exclusively from the sulphide or native cinnabar. It is extracted by two principal processes. According to one process, the mineral is picked, pounded, and mixed with lime. The mixture is then introduced into cast-iron retorts, which are placed in rows, one above the other, in an oblong furnace, and connected with earthenware receivers one-third full of water. Heat being applied, the lime combines with the sulphur, so as to form calcium sulphide and sulphate; while the mercury distils over, and is condensed in the receivers. The other process is practised at Almaden in Spain. Here a square furnace is employed, the floor of which is pierced with many holes, for the passage of the flame from the fireplace beneath. In the upper and lateral part of the furnace, holes are made, communicating with several rows of *aludels*, formed of adapters passing into one another, which terminate in a small chamber that serves both as condenser and receiver. The mineral, having been picked by hand and pulverized, is kneaded with clay, and formed into small masses, which are placed on the floor of the furnace. Heat being applied, the sulphur burns, and the volatilized mercury passes through the aludels to be condensed in the chamber. The process pursued at New Almaden is described by Dr. Ruschenberger. (*A. J. P.*, 1856.)

Mercury, as found in commerce, is contained in cylindrical wrought-iron bottles, called flasks, each containing 76½ pounds. Since the regular working of the California mine of New Almaden, the importation of the metal from Spain and Austria has gradually diminished, and at present the domestic production is sufficient not only to supply the home consumption, but to give an excess for exportation. In the year 1862 the different mines of California were said to be yielding mercury at the rate of four millions of pounds per annum (*A. J. P.*, Sept. 1862, 410), which had increased in 1877 to over six million pounds, but then fell off again. The production for 1895 was 33,978 flasks (of 76½ lbs.); for 1896, 29,863 flasks; for 1897, 26,079 flasks. The world's production for the year 1897 was about 111,765 flasks, or 8,550,000 lbs. The exports are made principally to China, Mexico, Chili, and Peru. The chief uses of the metal are in mining silver and gold, in preparing vermilion, in making thermometers and barometers, in silvering looking-glasses, and in forming various pharmaceutical compounds.

Properties. Mercury is "a shining, silver-white metal, without odor or taste. It is liquid at the ordinary temperature, and easily divisible into spherical globules; but, when cooled to

—39·38° C. (—38·88° F.), it forms a ductile, malleable mass. Specific gravity: 13·5584 at 15° C. (59° F.). Insoluble in the ordinary solvents, also in concentrated hydrochloric acid, and, at common temperatures, in sulphuric acid; but it dissolves in the latter, when boiled with it, and is readily and completely soluble in nitric acid. At ordinary temperatures it volatilizes very slowly, more rapidly as the temperature increases, and at 357·25° C. (675·05° F.) it boils, and is completely volatilized, yielding a colorless and very poisonous vapor. When globules of Mercury are dropped upon white paper, they should roll about freely, retaining their globular form, and leaving no streaks or traces. It should be perfectly dry and present a bright surface. On boiling 5 Gm. of Mercury with 5 C.c. of Water and 4·5 Gm. of sodium hyposulphite, in a test-tube, for about one minute, the Mercury should not lose its lustre, and should not acquire more than a slightly yellowish shade (absence of more than *slight traces of foreign metals*)." *U. S.* When perfectly pure it undergoes no alteration by the action of air or water, but in its ordinary state suffers a slight tarnish. When heated to near the boiling point, it gradually combines with oxygen, and is converted into mercuric oxide; but at the temperature of ebullition it parts with the oxygen with which it had combined, and is reduced again to the metallic state. Its sp. gr. is 13·5, and its atomic weight 199·8. It boils at 357·25° C. (669° F.), yielding a colorless vapor, and congeals at —39·4° C. (—39° F.), forming a malleable solid of tin-white color. It is a good conductor of heat, and its specific heat is small. It is not attacked by hydrochloric acid, nor by cold sulphuric acid; but boiling sulphuric acid or cold nitric acid dissolves it, producing mercurous sulphate and mercurous nitrate, respectively, with the extrication, in the former case, of sulphurous acid, in the latter, of nitrogen dioxide becoming hyponitric acid fumes. Its combinations are numerous, and several of them constitute important medicines. It forms two series of compounds, the *mercurous* compounds containing the group $(Hg_2)^{II}$, and the *mercuric* compounds containing the single atom Hg^{II}.

Mercury, as it occurs in commerce, is in general sufficiently pure for pharmaceutical purposes. Occasionally it contains foreign metals, as lead, tin, zinc, and bismuth. Mr. Brande informs us that in examining large quantities of this metal in the London market he found it in only one instance intentionally adulterated. When impure, the metal has a dull appearance, leaves a trace on white paper, is deficient in due fluidity and mobility, as shown by its not forming perfect globules, is not totally dissipated by heat, and when shaken in a glass bottle coats its sides with a pellicle, or, if very impure, deposits a black powder. If agitated with strong sulphuric acid, the adulterating metals become oxidized and dissolved, and thus the mercury may to a limited extent be purified. Lead is detected by shaking the suspected metal with equal parts of acetic acid and water, and then testing the acid by sodium sulphate or potassium iodide. The former will produce a white, the latter a yellow, precipitate, if lead be present. Bismuth is discovered by dropping a nitric solution of the mercury, prepared without heat, into distilled water, when bismuth subnitrate will be precipitated. The complete solubility of the metal in nitric acid shows that tin is not present; and, if hydrogen sulphide does not act upon hydrochloric acid previously boiled upon the metal, the absence of contaminating metals is shown. Mercury may be purified by digesting it with a small portion of weak nitric acid, or with a solution of mercuric chloride, whereby all the ordinary contaminating metals will be removed. The purification by nitric acid is, according to L. Meyer (*Zeit. Anal. Chem.*, ii. 241), best effected as follows. The metal is allowed to flow in a very thin stream from a small opening in a glass funnel into a wide glass tube 1·25 m. high and 5 cm. in diameter, which contains a dilute mixture of water and nitric acid. A narrow tube is fastened to the bottom of this, from which the pure metal flows; it has then only to be washed with water and dried. The above operation may have to be repeated several times, and the metal if pure must leave no residue when dissolved in pure nitric acid, evaporated to dryness, and ignited. To separate mechanical impurities, moisture, or small quantities of oxide, mercury may be filtered by collecting it in a sound piece of chamois leather and gathering the corners together, forcibly squeezing the particles through the pores of the leather. Mercury, however, is usually purified by distillation.* Being much more volatile than the contami-

* The British Pharmacopœia of 1864 gave the following process for the purification of mercury, using for this purpose an impure form of the metal, under the name of *Commercial Mercury* or *Quicksilver*:

"Take of Mercury of Commerce *three pounds* [avoirdupois]: Hydrochloric Acid *three fluidrachms*: Distilled Water *a sufficiency*. Place the Commercial Mercury in a glass retort or iron bottle, and applying heat cause two pounds and a half of the metal to distil over into a flask employed as a receiver. Boil on this for five minutes the Hydrochloric Acid diluted with nine fluidrachms of Distilled Water, and having, by repeated affusions of Distilled Water and decantations, removed every trace of acid, let the mercury be transferred to a porcelain capsule, and dried first by filtering paper, and finally on a water-bath." *Br.*

nating metals, it rises first in distillation, while they are left behind. But it is necessary to avoid pushing the distillation too far; for in that event some of the foreign metals are apt to be carried over. The British Council, on account of this danger, directed only five-sixths of the mercury to be distilled. The distilled product is boiled for a few minutes with diluted hydrochloric acid, which, while it does not attack the mercury, dissolves any contaminating metals which may have passed over. The distillation is directed to be performed from a glass retort or iron bottle; but it is more conveniently conducted from the latter, over a common fire, into water contained in a receiver. In small operations a wash-hand basin will answer for a receiver. Millon has ascertained the curious fact that the presence of so small a quantity as one ten-thousandth of lead or zinc in mercury raises its boiling point. M. Violette has made known a method of distilling mercury, or amalgamated silver, which presents many advantages. It consists in subjecting the metal, in iron vessels, to a current of high-pressure steam, which serves the double purpose of imparting the necessary heat, and carrying over the mercurial vapor by a mechanical agency. (*Philos. Mag.*, Dec. 1850.) As it is difficult and troublesome to purify mercury by distillation, it is better to purchase pure samples of the metal, which may always be found in the market.

Mercury is detected with great delicacy by Smithson's process, which consists in the use of a plate of tin, lined with one of gold, in the form of a spiral. When immersed in a mercurial solution, this galvanic combination causes the precipitation of the mercury on the gold, which consequently contracts a white stain. In order to be sure that the stain is caused by mercury, the metal must be volatilized in a small tube, so as to obtain a characteristic globule. MM. Danger and Flandin have improved on Smithson's process. (See *Chem. Gaz.*, No. 61, p. 191.) A minute portion of any of the preparations of mercury, either in the solid state or in concentrated solution, being placed on a bright plate of copper, and a drop of a strong solution of potassium iodide added, a silvery characteristic stain will immediately appear on the copper.

Medical Properties. Mercury in its uncombined state is inert, but in combination acts as a peculiar and universal stimulant. When exhibited in minute division, as it exists in several preparations, it produces its peculiar effects; but this does not prove that the uncombined metal is active, but only that the condition of minute division is favorable to chemical combination, and consequently to its solution in the stomach. Its compounds exhibit certain general medical properties and effects which belong to the whole as a class; while each individual preparation is characterized by some peculiarity in its operation. In this place we shall consider the physiological action of mercury, and the principles by which its administration should be regulated; while its effects as modified in its different combinations will be noticed under the head of the several preparations. Of the modus operandi of mercury we know nothing, except that it possesses a peculiar alterative power over the vital functions. This alterative power is sometimes exerted without being attended with any other vital phenomenon than the removal of disease; while at other times it is accompanied with certain obvious effects, such as a quickened circulation, a frequent jerking pulse, and increased activity of all the secretory functions, particularly those of the salivary glands and the liver. When mercury acts slowly as an alterative, there is not the least apparent disturbance of the circulation. When it operates decidedly and obviously, it is very prone to cause an immoderate flow of saliva and produce the condition denominated ptyalism or salivation. Mercury has been detected in most of the solids and fluids of the body, including the blood. When in the blood it cannot be detected by the ordinary tests, on account of its intimate union with the organic matter of that liquid. To discover it, the blood must be subjected to destructive distillation. The liver is the organ which retains mercury the longest. It has been detected in that viscus though absent in the lungs, heart, bile, and spinal marrow.* Mercury has been used in almost every disease, but too often with evil results. In functional derangement of the digestive organs, mercurials in minute doses often exert a salutary operation, subverting the morbid action, and that, too, by their slow, alterative effect, without affecting the mouth. In these cases no decided disturbance of the vital functions takes place; but the alvine discharges, if clay-colored, are generally restored to their natural hue: whether the liver be torpid and obstructed as in jaundice, or pouring out a redundancy of morbid bile as in melæna, the judicious use of mercury seems equally efficacious in unloading the viscus, or restoring its secretion to a healthy state. In chronic inflammation of the mucous and serous membranes, the alterative effects of mercury are sometimes attended with much benefit. In many of these cases effusion has taken place; and under these

* For a method of detecting mercury in the urine, see *P. J. Tr.*, Aug. 1873, 145.

circumstances the mercury often proves useful as well by promoting absorption as by removing the chronic inflammation on which the effusion depends. Hence it is often given with advantage in chronic forms of *meningitis*, *bronchitis*, *pleuritis*, *pneumonitis*, *dysentery*, *rheumatism*, etc., and in *hydrocephalus*, *hydrothorax*, *ascites*, and *general dropsy*. Mercury may also be advantageously resorted to in certain states of febrile disease. In some forms of *remittent* and *typhoid fever*, a particular stage is marked by a parched tongue, torpor of the bowels, scanty urine, and dryness of the surface. Here the very cautious employment of mercury is sometimes serviceable. It acts in such cases by increasing the secretions.

In syphilitic affections, mercury, until of late years, was held to be indispensable. Of its mode of action in these affections we know nothing. Without entering into the question of the necessity of mercury in venereal complaints, we are free to admit that the discussion which has grown out of it has shown that this remedy has frequently been unnecessarily resorted to in syphilis. For inducing the specific effects of mercury on the constitution, blue pill or calomel is generally resorted to. In order to procure what we have called the slow alterative effects of the metal, from half a grain to a grain (0·03 to 0·067 Gm.) of blue pill may be given in the twenty-four hours, or from a sixth to a fourth of a grain (0·01 to 0·016 Gm.) of calomel; or, if a gentle ptyalism be our object, two or three grains (0·13 or 0·20 Gm.) of the former, or a grain of the latter (0·067 Gm.) two or three times a day. Where the bowels are peculiarly irritable, it is often necessary to introduce the metal by means of friction with mercurial ointment; and where a speedy effect is desired, the internal and external use of the remedy may be simultaneously resorted to.

The first observable effects of mercury in inducing ptyalism are a coppery taste in the mouth, a slight soreness of the gums, and an unpleasant sensation in the sockets of the teeth when the jaws are firmly closed. Shortly afterwards the gums begin to swell, a line of whitish matter is seen along their edges, and the breath is infected with a peculiar and very disagreeable smell, called the mercurial fetor. The saliva at the same time begins to flow; and, if the affection proceed, the gums, tongue, throat, and face become much swollen; ulcerations attack the lining membrane of the mouth and fauces; the jaws become excessively painful; the tongue is coated with a thick whitish fur; and the saliva flows in streams from the mouth. It occasionally happens that the affection of the mouth proceeds to a dangerous extent, inducing extensive ulceration, gangrene, and even hemorrhage. The best remedies are astringent and detergent gargles, used weak at first, as the parts are extremely tender. In cases attended with swelling and protrusion of the tongue, the wash is best applied by injection by means of a large syringe. We have found lead water among the best applications in these cases; and dilute solutions of chlorinated soda or of chlorinated lime, while they correct the fetor, will be found to exert a curative influence on the ulcerated surfaces. A wash of silver nitrate, made by dissolving eight grains (0·52 Gm.) in a fluidounce (30 C.c.) of water, has also been used with benefit. While the system is under the action of mercury the blood is more watery than in health, less charged with albumen, fibrin, and red globules.

In the foregoing observations we have described the ordinary effects of mercury; but occasionally, in peculiar constitutions, its operation is quite different, being productive of a dangerous disturbance of the vital functions. The late Mr. Pearson gave a detailed account of this occasional peculiarity in the operation of mercury, in his work on the venereal disease. The symptoms which characterize it are a small and frequent pulse, anxiety about the præcordia, pale and contracted countenance, great nervous agitation, and alarming debility. Their appearance is the signal for discontinuing the mercury, as a further perseverance with it might be attended with fatal consequences. Mercury also produces a peculiar eruption of the skin, which is described by writers under the various names of *hydrargyria*, *eczema mercuriale*, and *lepra mercurialis*. Those who work in mercury, and are, therefore, exposed to its vapor, such as water-gilders, looking-glass silverers, and quicksilver miners, are injured seriously in their health, and not unfrequently affected with shaking palsy, attended with vertigo and other cerebral disorders. The miners are often salivated.

Many plants, exposed to the influence of the vapor spontaneously rising from mercury in confined air, perish in a few days; while if sulphur be placed by the side of the metal no effect of the kind is experienced. (Boussingault, *Journ. de Pharm. et de Chim.*, Sept. 1867, p. 176.) A probable inference from this fact is that workmen necessarily exposed to the vapor of mercury might be protected by the presence of sulphur in sufficient quantity.

Mercury is sometimes given in the metallic state, in the quantity of a pound or two, in obstruction of the bowels, to act by its weight; but the practice is of doubtful advantage.

HYDRARGYRUM AMMONIATUM. U. S., Br. Ammoniated Mercury.

[White Precipitate. Mercuric Ammonium Chloride.]

NH_2HgCl; 251·18. (HĬ-DRĂR'ĢĬ-RŬM ĄM-MŌ-NĮ-Ā'TŬM.) NH_2HgCl; 251·1.

Ammonio-Chloride of Mercury; Hydrargyri Precipitatum Album; Hydrargyri Ammonio-Chloridum.

"Corrosive Mercuric Chloride, in powder, *one hundred grammes* [or 3 ounces av., 230 grains]; Ammonia Water, Distilled Water, each, *a sufficient quantity*. Dissolve the Corrosive Mercuric Chloride in *two thousand cubic centimeters* [or 67 fluidounces, 5 fluidrachms] of warm Distilled Water, filter the solution, and allow it to cool. Pour the filtered liquid gradually, and with constant stirring, into *one hundred and fifty cubic centimeters* [or 5 fluidounces, 34 minims] of Ammonia Water, taking care that the latter shall remain in slight excess. Collect the precipitate on a filter, and, when the liquid has drained from it as much as possible, wash it with a mixture of *four hundred cubic centimeters* [or 13 fluidounces, 252 minims] of Distilled Water and *twenty cubic centimeters* [or 324 minims] of Ammonia Water. Finally, dry the precipitate between sheets of bibulous paper, in a dark place, at a temperature not exceeding 30° C. (86° F.). Keep the product in well-stoppered bottles, protected from light." *U. S.*

"Mercuric Chloride, 3 *ounces* (Imperial) or 60 grammes; Solution of Ammonia, 4 *fl. ounces* (Imp. meas.) or 80 cubic centimetres; Distilled Water, *a sufficient quantity*. Dissolve the Mercuric Chloride in *three pints* (Imp. meas.) or twelve hundred cubic centimetres of the Distilled Water with the aid of heat; pour the liquid into the Solution of Ammonia diluted with *one pint* (Imp. meas.) or four hundred cubic centimetres of Distilled Water, constantly stirring; collect the precipitate on a filter; wash it well with cold Distilled Water until the liquid which passes through is free from chloride; dry the product at a temperature not exceeding 212° F. (100° C.)." *Br.*

The Pharmacopœias now agree in obtaining white precipitate by precipitating a solution of mercuric chloride by ammonia. When ammonia, in slight excess, is added to a cold solution of mercuric chloride, ammonium chloride is formed in solution, and the white precipitate of the Pharmacopœias thrown down. The precipitate is washed twice, according to the U. S. formula, according to the British, with greater precision, until the washings cease to give evidence of the presence of a chloride by producing a precipitate with silver nitrate acidulated with nitric acid. The substance washed away is ammonium chloride with the excess of ammonia employed; and hence the washings, agreeably to the directions of the British formula, are tested with an acid solution of silver nitrate. The white precipitate forms according to the following reaction: $HgCl_2 + 2NH_3 = NH_4Cl + NH_2HgCl$. In other words, one molecule of mercuric chloride reacts with two of ammonia, and yields one molecule of ammonium chloride and one of *mercur-ammonium chloride*, or white precipitate. A method of making white precipitate, said to be employed by large manufacturers, substitutes ammonium chloride and sodium carbonate for ammonia. As the product contains less mercury than the official preparation, and is in commerce, it is important to be able to distinguish the two. According to Prof. Redwood, this can be done by heating, the official preparation volatilizing without fusing, the unauthorized fusing before volatilizing: Prof. Attfield has, however, shown that fusibility does not necessarily indicate that the specimen contains only 65 per cent. of mercury, nor infusibility demonstrate that it contains the official proportion of 79½ per cent. The commercial variety differs somewhat from the present official preparation in composition, its formula being $N_2H_6HgCl_2$ (or *mercur-diammonium chloride*). (See paper by F. X. Moerk, *A. J. P.*, 1888.)

Properties. "White, pulverulent pieces, or a white, amorphous powder, without odor, and having an earthy, afterwards styptic and metallic taste. Permanent in the air. Almost insoluble in water or in alcohol. By prolonged washing with water it is gradually decomposed, assuming a yellow color, and becoming converted into a basic salt. Readily soluble in warm hydrochloric, nitric, or acetic acid, and in a cold solution of ammonium carbonate. Also completely soluble in a cold solution of sodium hyposulphite, with the evolution of ammonia. When this solution is heated for a short time, red mercuric sulphide is separated, which, on protracted boiling, turns black. At a temperature below a red heat the salt is decomposed without fusion, and at a red heat it is wholly volatilized. When heated with potassium or sodium hydrate test-solution, the salt turns yellow, and evolves vapor of ammonia. The solution of the salt in diluted nitric acid gives with potassium iodide test-solution a red precipitate, and with silver nitrate test-solution a white one. The salt should be soluble in hydrochloric acid without effervescence (absence of *carbonate*), and without leaving a residue (absence of *mercurous salt*). Its solution in acetic acid should not be rendered turbid by diluted sulphuric

acid (absence of *lead*)." *U. S.* "A white powder on which *water* has but little action, and *alcohol* (90 per cent.) or *ether* no action. Digested with *solution of potassium hydroxide*, it evolves ammonia, acquiring a pale yellow color, and the liquid, filtered and acidulated with *nitric acid*, gives a white precipitate with *solution of silver nitrate*. Boiled with *solution of stannous chloride* it becomes gray, and yields globules of metallic mercury. It volatilizes at a temperature under redness, without fusing, leaving only an insignificant amount of fixed residue. When heated with excess of *lime* it should yield 78 to 79 per cent. of metallic mercury." *Br.*

Adulteration with white lead, chalk, or calcium sulphate may be detected by exposing a sample to a strong red heat, when these impurities will remain. Should starch be mixed with it, a charred residue will be obtained on the application of heat. Lead or starch may be found by digesting it with acetic acid, and testing the acetic solution with the compound solution of iodine, which will give a yellow precipitate if lead and a blue one if starch be present. The absence of mercurous oxide is shown by its not being blackened when rubbed with lime water. Ammoniated mercury is used only as an external application. Mercur-diammonium chloride is said to produce an ointment more translucent and less beautifully white than the genuine, and more apt to become yellow on being kept. (J. Borland, *P. J. Tr.*, Dec. 1867, p. 262.)

Ammoniated mercury has been swallowed by mistake. It is highly poisonous, producing gastric pain, nausea, and purging. For recovery after taking half a drachm, see *London Lancet*, July 4, 1857. The remedies employed were an emetic of zinc sulphate and milk.

HYDRARGYRUM CUM CRETA. U. S., Br. Mercury with Chalk.

(HĬ-DRĂR'ĢĬ-RŬM CŬM CRĒ'TĄ.)

Grey Powder; Mercure avec la Craie, Poudre de Mercure crayeux, *Fr.*; Quecksilber mit Kreide, *G.*

"Mercury, *thirty-eight grammes* [or 1 ounce av., 149 grains]; Clarified Honey, *ten grammes* [or 154 grains]; Prepared Chalk, *fifty-seven grammes* [or 1 ounce av., 442 grains]; Water, *a sufficient quantity*, To make *one hundred grammes* [or 3 ounces av., 230 grains]. Weigh the Mercury and Clarified Honey successively into a strong bottle of the capacity of *one hundred cubic centimeters* [or 3 fluidounces, 183 minims], and add *two cubic centimeters* [or 32 minims] of Water. Cork the bottle, and shake it for about half an hour at a time, until the aggregate time of shaking reaches ten hours, or until the globules of Mercury are no longer visible under a lens magnifying *four diameters*. (The shaking may be more conveniently performed by mechanical means.) Rub the Prepared Chalk with Water, in a mortar, to a thick, creamy paste, and, having added the contents of the bottle, washing the last portions in with a little Water, triturate the whole to a uniform mixture. Finally, dry the mixture, first between ample layers of bibulous paper, and afterwards in a capsule, at the ordinary temperature, until it weighs *one hundred grammes* [or 3 ounces av., 230 grains]. Then reduce it to a uniform powder, without trituration, and keep it in well-stoppered bottles, protected from light." *U. S.*

"Mercury, 1 *ounce* (Imperial) or 20 grammes; Prepared Chalk, 2 *ounces* (Imp.) or 40 grammes. Rub the Mercury and Prepared Chalk in a porcelain mortar until metallic globules cease to be visible to the naked eye, and the mixture acquires a uniform grey color." *Br.*

The method of making this mercurial directed by the U. S. P. 1880 was so faulty as to be inoperative, and it has been abandoned; the U. S. P. 1890 process for making mercury with chalk is based upon Dr. Squibb's method of succussion, which is described at length farther on. When mercury is triturated with certain dry and pulverulent substances, such as chalk or magnesia, it gradually loses its fluidity and metallic lustre and becomes a blackish or dark-gray powder. A similar change takes place when it is rubbed with viscid or greasy substances, such as honey or lard. The globules disappear, so as in some instances not to be visible even through a good lens; and the mercury is said to be extinguished. It was formerly thought that the metal was oxidized in the process. At present the change is generally ascribed to the mechanical division of the metal, which in this state is supposed to be capable of acting on the system. There is good reason, however, to believe that in this, as in all the analogous preparations of mercury in which the metal is extinguished by trituration, a very small portion is converted into mercurous oxide, while by far the greater part remains in the metallic state. Mercury with chalk is officially described as a "a light gray, rather damp powder, free from grittiness, without odor, and having a slightly sweetish taste. If a portion of the powder be digested with warm acetic acid, the chalk is dissolved with effervescence, leaving a residue of

finely divided mercury. The filtrate should not become more than slightly opalescent on the addition of a few drops of hydrochloric acid (limit of *mercurous oxide*). If another portion of the powder be digested with warm, diluted hydrochloric acid, the filtrate should not be affected by hydrogen sulphide test-solution, or by stannous chloride test-solution (absence of *mercuric oxide*)." *U. S.* "A powder of a light grey color; free from grittiness; insoluble in *water;* partly dissolved by *diluted hydrochloric acid*, leaving the mercury in a finely divided state. The solution formed with *hydrochloric acid* does not yield any white or grey precipitate on the addition of *solution of stannous chloride* (absence of mercuric compounds)." *Br.* Robert B. Matter suggests an improved process for its preparation whereby labor and time are saved; it is as follows. Mix twelve parts of finely powdered gum arabic with twelve parts of prepared chalk, triturate with sufficient water to form a rather thin paste, add thirty-eight parts of mercury, and continue the trituration until the globules of mercury have disappeared. Now add thirty-eight parts of finely powdered prepared chalk and sufficient water to form a thin paste, triturate, and when all the globules of mercury have disappeared, place the mortar in a hot water-bath. The mixture distributed around the sides of the mortar will dry rapidly, when it can be easily scraped out, powdered in a clean mortar, passed through bolting-cloth, or a fine sieve, and finally rubbed lightly in a clean dry mortar: 8 ounces may be made by this process in an hour. (*A. J. P.*, 1886, 119.)

Mercury with chalk is a smooth, grayish powder, insoluble in water. Globules of mercury can generally be seen in it by the aid of a microscope, as the metal can scarcely be completely extinguished with chalk alone by any length of trituration. Mr. Jacob Bell found that by powerfully pressing it a considerable quantity of metal was separated in the form of globules. Mr. Phillips states that the extinguishment of the mercury is greatly accelerated by the addition of a little water. Dr. Stewart, of Baltimore, proposed the following process, by which he stated that the preparation might be completed in a short time, so that no globules should be visible with a powerful lens. Three ounces of mercury and six ounces of resin are to be rubbed together for three hours; five ounces of chalk are to be added, and the trituration continued for an hour; the mixture is then to be heated with alcohol so as to dissolve the resin; and the remaining powder is to be dried on bibulous paper and well rubbed in a mortar. (*A. J. P.*, xv. 162.) But Professor Procter showed that the preparation thus made contains mercuric oxide, and is, therefore, injuriously harsh in its operation. (*Ibid.*, xxii. 113.) It is said that the precipitated black oxide is sometimes added with a view to save time in the trituration; but this must be considered as an adulteration, until it can be shown that the same oxide exists in the same proportion in the preparation made according to the official directions. Dr. Ed. Jenner Coxe, of New Orleans, found that the extinguishment of the mercury may be effected much more speedily than in the ordinary manner, by putting the ingredients into a quart bottle, to be well corked, and kept in constant agitation till the object is attained. A portion of chalk may be thus shaken with the metal until no globules can be seen, and the process completed by trituration with the remainder of the chalk in a mortar. This mode of proceeding was suggested to Dr. Coxe by Mr. W. Hewson, of Augusta, Ga. (*Ibid.*, xxii. 317.) Dr. Squibb, having ascertained that the preparation cannot be satisfactorily made in this way on a large scale (*Proc. A. P. A.*, 1858, p. 424), has invented a machine for accomplishing the same object, by which the requisite motion is imparted to the materials contained in two large bottles, and which is said to answer the purpose well. By means of this apparatus, Dr. Squibb prepares mercury with chalk on a large scale, mixing the materials in the official proportions, but aiding the extinguishment of the metal by adding about one-seventh of its weight of honey, and adding this to the chalk made into a paste with water, and afterwards drying. (*Ibid.*, 1859, p. 359.) It has been shown that the preparation thus made resists oxidation most effectually, owing probably to the presence of saccharine matter. (J. P. Remington, *A. J. P.*, Jan. 1869.) W. E. Bibby (*A. J. P.*, 1876, p. 269) recommends the rubbing of 3 troyounces of mercury, 4 troyounces of prepared chalk, and 1 troyounce of sugar of milk together in a mortar into an impalpable powder and passing the powder through a fine sieve. As found in commerce, mercury with chalk, instead of being the mild preparation intended, sometimes acts very harshly, causing vomiting, gastric pains, etc. This has been ascribed to the presence of antimony or arsenic, which, however, must be rare: the ordinary cause of the harshness is no doubt mercuric oxide, produced in minute proportion either during the trituration, or by the spontaneous change which occurs with time, mercurous oxide becoming mercuric oxide by the influence of light. The only sure method to guard against such results is to test the preparation carefully before dispensing it. (See *A. J. P.*, 1878, p. 325.) If the mercury contained

in it be volatilized by heat, and the remaining chalk be dissolved by dilute acetic acid, the solution should not be colored by hydrogen sulphide. The presence of any probable metallic impurity may be detected in this way. To detect mercuric oxide, a portion of the powder may be treated with diluted hydrochloric acid with a moderate heat, and the solution tested by stannous chloride, which, if there be any mercuric oxide present, will cause a precipitation of metallic mercury as a black powder.

Medical Properties and Uses. Mercury with chalk is a very mild mercurial, similar in its properties to the blue mass, but much weaker. It is sometimes used as an alterative, particularly in the complaints of children attended with deficient biliary secretion, indicated by white or clay-colored stools. The chalk is antacid, and, though in small quantity, may sometimes be a useful accompaniment of the mercury in *diarrhœa*. Eight grains of the U. S. preparation contain about three grains of mercury. The dose is from five grains to half a drachm (0·33–1·95 Gm.) twice a day. From two to three grains (0·13–0·20 Gm.) is the dose for a child. It should not be given in pill with substances which become hard on keeping, as the contraction of the mass presses together the particles of mercury, which in time appear in globules in the interior of the pill.

HYDRASTININÆ HYDROCHLORAS. U. S. Hydrastinine Hydrochlorate.

$C_{11}H_{11}NO_2HCl$; 224·97. (HĪ-DRĂS-TĮ-NĪ'NÆ HĪ-DRŌ-ȻHLŌ'RĂS.)

"The hydrochlorate of an artificial alkaloid derived from hydrastine, the latter being a colorless alkaloid obtained from Hydrastis. Hydrastinine Hydrochlorate should be kept in well-stoppered vials." *U. S.*

This is a new official salt, being introduced for the first time in the U. S. P. 1890. *Hydrastinine* is an artificial alkaloid, produced by acting on hydrastine, the alkaloid from hydrastis, with oxidizing agents. When manganese dioxide and sulphuric acid are used together, or when platinic chloride is employed, hydrastinine and *opianic acid* are the products.* (See *Hydrastis.*) Hydrastinine hydrochlorate is officially described as in "light yellow, amorphous granules, or a pale yellow, crystalline powder, odorless, and having a bitter, saline taste; deliquescent on exposure to damp air. Soluble, at 15° C. (59° F.), in 0·3 part of water, and in 3 parts of alcohol; difficultly soluble in ether or chloroform. When heated to 173° C. (343·4° F.), the salt undergoes partial fusion, but does not liquefy. Upon ignition, it is consumed, leaving no residue. The salt has an acid reaction upon litmus paper. A dilute aqueous solution of the salt (up to about 1 in 100,000) has a decided blue fluorescence. The salt dissolves in sulphuric acid with effervescence, coloring the acid yellowish-red. An aqueous solution of the salt is not precipitated by ammonia water. An aqueous solution of the salt yields, with silver nitrate test-solution, a white precipitate insoluble in nitric acid. On adding to 2 C.c. of an aqueous solution of the salt (1 in 100) an excess of bromine water, a yellow precipitate is produced, which is dissolved by ammonia water to a nearly colorless liquid (difference from *hydrastine*, with which the ammonia produces a brick-red precipitate." † *U. S.*

Medical Properties and Uses. Hydrastinine is, when given in large enough amount, a powerful depressant to the whole motor tract, affecting the psycho-motor centres of the cerebral cortex, the motor nerve, and the muscle itself. In the present state of our knowledge it is uncertain whether the depression is or is not preceded by a brief period of excitation, but it is almost certain that there is a primary stimulation of the muscles. The alkaloid slows the action of the heart but increases the force of the beat, and markedly augments the blood-pressure, contracting actively the blood-vessels by stimulating both the vaso-motor centres and the muscles in the walls of the arterioles. In the toxic dose it finally paralyzes respiration, although there is reason for believing that in the beginning it stimulates the function.

* E. Schmidt, in studying this production of hydrastinine by oxidation from hydrastine, was led to make some interesting comparisons between hydrastine and narcotine. The latter of these he considers to contain three methyl groups, thus, $C_{19}H_{14}(OMe)_3NO_4$, while the former contains only two, thus, $C_{19}H_{15}(OMe)_2NO_4$. Since the oxidation of narcotine with manganese dioxide and sulphuric acid yields opianic acid and cotamine, and under the same conditions hydrastine gives opianic acid and hydrastinine, and, further, as opianic acid contains two methyl groups and cotamine one of these groups, as shown by Wright, it follows that hydrastinine contains no methyl group, and cotamine may prove to be a methylated hydrastinine. The author hopes later to succeed in converting hydrastine into narcotine. (*A. J. P.*, 1888, p. 635.)

† *Hydrohydrastinine hydrochlorate*, $C_{11}H_{13}NO_2HCl$, is obtained by fractioning hydrastinine. It occurs as a white powder, soluble in water. The dose in uterine hemorrhage is one-third of a grain (0·021 Gm.), preferably given in capsules.

Death occurs from asphyxia, to which is usually ascribed the final fall of the arterial pressure. Although there has been some conflict of evidence, it seems finally established that hydrastinine is a powerful oxytocic. According to the experiments of Archangelsky, its administration to pregnant animals is very commonly followed by abortion. According to Faber, when given hypodermically during human parturition, it very notably increases the force and length of the uterine contraction, and is capable, in sufficient dose, of causing a tonic spasm of the uterus similar to that produced by ergot. Its action upon the uterus appears to be independent of any other of its influences, and to be direct. It would seem that it is a universal muscle-poison, primarily stimulant in its action, and that in this way it affects the heart, the arterioles, and the uterus. According to Von Bunge, it markedly increases peristalsis, so that even the intestines do not escape its muscular action.

Hydrastinine was originally recommended by Falck in the treatment of *menorrhagia*, *metrorrhagia*, *dysmenorrhœa*, and even *endometritis*. The testimony as to its value in all forms of uterine hemorrhage seems to be conclusive, and it is affirmed by many gynæcologists that it has a pronounced alterative influence upon the mucous membrane of the uterus. From our own experience we are convinced that it has value as a cardiac tonic, not equal in power or certainty of action to digitalis, but often useful as a substitute for that drug, especially in minor cases of heart-failure. Its sedative action on the centric nervous system, conjoined with its stimulating influence upon the circulation and its pronounced effects upon the genital system, make it a very valuable remedy in the treatment of feeble women of hysterical temperament, with tendency to uterine fluxes. The dose usually employed is from three-quarters of a grain to one and a half grains (0·05 to 0·09 Gm.) every three to six hours, but probably larger doses might often be used with advantage, since no ill effects have been as yet recorded as being produced by it. The salt may be given hypodermically.

HYDRASTIS. U. S. (Br.) Hydrastis. [Golden Seal.]

(HĬ-DRĂS'TIS.)

"The rhizome and roots of Hydrastis Canadensis, Linné (nat. ord. Ranunculaceæ)." *U. S.*
"The dried rhizome and roots of Hydrastis canadensis, Linn." *Br.*

Hydrastis Rhizoma, *Br.;* Hydrastis Rhizome; Rhizoma Hydrastis; Golden Seal, Yellow Root, Yellow Puccoon, Orange Root, Indian Dye, Indian Turmeric; Racine d'Hydrastis de Canada. *Fr.;* Canadische Gelbwurzel, *G.*

Hydrastis canadensis. Gray, *Manual of Bot.*, 14; figured in Griffith's *Med. Bot.*, 82. This is a small, herbaceous, perennial plant, with a thick, fleshy, yellow rhizome, from which numerous long roots arise, and an erect, simple, pubescent stem, from six inches to a foot in height. There are usually but two leaves, which are unequal, one sessile at the top of the stem, the other attached to the stem a short distance below by a thick roundish footstalk, causing the stem to appear as if bifurcate near the summit. The leaves are pubescent, roundish-cordate, with from three to seven, but generally five, lobes, which are pointed and unequally serrate. A solitary flower stands upon a peduncle rising from the basis of the upper leaf. It is whitish, rose-colored, or purplish, without corolla, but with a colored calyx, the sepals of which closely resemble petals, and are very caducous, falling very soon after the flower has expanded. The fruit is a globose, compound, red or purple berry, half an inch or more in diameter, composed of many fleshy carpels, each tipped with a short curved beak, and containing one or rarely two seeds. The plant grows in moist, rich woodlands in most parts of the United States, but abundantly in the North and West. The fruit bears a close resemblance to the raspberry, but is not edible. The root is the part used. The Indians employed it for staining and dyeing yellow, and it is said to impart a rich and permanent yellow, and with indigo a fine green, to wool, silk, and cotton. There is but one other species of Hydrastis known,—viz., *H. jezoensis* Sieb. et Zucc., which is found in Northern Japan.

Properties. The fresh root is juicy, and loses much of its weight in drying. The dried caudex is officially described as "about 4 Cm. long and 6 Mm. thick; oblique, with short branches, somewhat annulate and longitudinally wrinkled; externally brownish gray; fracture short, waxy, bright reddish yellow, with a thickish bark, about ten narrow wood-wedges, broad medullary rays, and large pith. Roots thin, brittle, with a thick, yellow bark and subquadrangular, woody centre. Odor slight; taste bitter." *U. S.* The rhizome breaks with a clean resinous fracture, leaving a smooth brownish-yellow or greenish-yellow surface, exhibiting a ring of bright yellow with somewhat distant narrow wood-bundles. Many of the

detached rootlets are mixed with the rhizomes in mass. The color of the rhizome, though yellow in the recent root, becomes a dark yellowish brown by age; that of the rootlets and the interior of the root is yellow, and that of the powder still more so. The odor is sweetish, and somewhat narcotic, the taste bitter and peculiar. The medicine imparts its virtues and coloring matters to water and alcohol. Examined by Mr. Alfred A. B. Durand, of Philadelphia, it was found to contain albumen, starch, fatty matter, resin, yellow coloring matter, sugar, lignin, and various salts. He also discovered a peculiar nitrogenous, crystallizable substance, for which he proposed the name of *hydrastine*. (*A. J. P.*, 1851, p. 112.) It has also been determined that the root contains another alkaloid, to which it owes its yellow color, and which is probably identical with the yellow coloring matter of Mr. Durand. Mr. F. Mahla first ascertained that this new alkaloid of hydrastis is *berberine*.* (*Am. Journ. of Sci. and Arts*, Jan. 1862, p. 43.) It exists in large proportion in hydrastis, constituting, according to Perrins, nearly 4 per cent. There can be no doubt that this medicine owes much of its virtue to berberine. For a valuable paper by Prof. J. U. Lloyd on the preparation of salts of berberine, see *A. J. P.*, 1879, p. 11. A substance obtained by the precipitation of an infusion of the root by hydrochloric acid has been for some time known and used by the "Eclectics," under the name of *hydrastin;* it consists of variable proportions of hydrastine, berberine, and resin (*A. J. P.*, 1876, p. 386), and the reader must be cautious not to confound this substance with the alkaloid to which the name properly belongs.

Hydrastine, which is the characteristic alkaloid, may be obtained by exhausting the powdered root as far as possible with water by percolation, adding hydrochloric acid to the infusion so as to precipitate the berberine in the form of hydrochlorate, and treating the mother-liquor with solution of ammonia in slight excess. The hydrastine is precipitated, in an impure state, and may be purified by repeated solution in boiling alcohol, which deposits it in crystals on cooling. A little animal charcoal may be used towards the close of the process, in order to deprive the crystals completely of color. To Mr. Mahla, of Chicago, and Mr. Perrins, of Lon-

* *Berberine.* This alkaloid appears to have been first discovered, in 1826, in a species of Xanthoxylum, by Chevallier and Pelletan, who, from its color and taste, named it *xanthopicrite;* Buchner and Herberger, in 1835, found it in *Berberis vulgaris*, and named it berberine; but none of these chemists were aware of its alkaline properties. Indeed, the substance obtained by them, at least the berberine of Buchner, must have been a native salt of the proper alkaloid, which was not, therefore, procured in a pure state. Subsequently Fleitmann demonstrated its basic character, and published an account of several of its salts. It is not confined to the barberry, but has been found, by various chemists, in several other plants, particularly those combining bitterness and a yellow color, as in various products of *Cocculus palmatus, Hydrastis canadensis, Xanthorrhiza apiifolia, Coptis teeta, Xanthoxylum clava herculis, Coscinium fenestratum*, and others belonging to the natural families of Berberaceæ, Menispermaceæ, and Ranunculaceæ. Indeed, few if any of the known alkaloids are so widely diffused as this appears to be in the vegetable kingdom. A list of the plants from which it has been obtained is contained in *A. J. P.*, Sept. 1863, p. 456.

Berberine may be obtained most readily from its sulphate. Prof. Procter has given the following process for preparing it, based upon a suggestion of Mr. Merrill, of Cincinnati. The coarsely-powdered root is to be exhausted by repeated decoction with boiling water, and the mixed liquids, after filtration, are to be evaporated to a soft extract. This is to be digested several times with stronger alcohol, in the proportion of a pint to half a pound of the root, until exhausted, one-fourth of its bulk of water is to be added to the tincture, and five-sixths of the alcohol to be distilled off. To the residue, while still hot, sulphuric acid is to be added in excess, and the liquid allowed to cool. The sulphate of berberine is deposited in crystals, and, having been purified by recrystallization, is to be decomposed by the addition, in excess, to its solution in boiling water, of freshly precipitated lead protoxide, the solution being kept hot until the decomposition is completed. This may be known by the absence of a precipitate when lead acetate is added to a drop of the clear liquid. The liquid is then to be filtered, and set aside to crystallize. Thus obtained, berberine is in the form of a yellow powder, which, under the microscope, appears to consist of groups of minute, acicular crystals. It has a bitter taste, is soluble in about 100 parts of cold water, still less soluble in cold alcohol, freely soluble in both these liquids when hot, and insoluble in ether. It forms salts of difficult solubility with hydrochloric and sulphuric acids, and is distinguished by being copiously precipitated by the former acid from its cold watery solution in the form of crystals of the hydrochlorate. It is freely dissolved by acetic acid, which forms with it a readily soluble salt. (*A. J. P.*, Jan. 1864, 10.) Its formula is, on the authority of Perrins, $C_{20}H_{17}NO_4$. (*P. J. Tr.*, April, 1863, 464.) Hlasiwetz (*Ann. Ch. Pharm.*, 115, 45) also confirms this formula, which may therefore be assumed as correct. *Berberine hydrochlorate*, which is the salt that has attracted most notice, may be readily obtained by using hydrochloric instead of sulphuric acid in the above process, and purifying the precipitate by solution in hot alcohol, and subsequent refrigeration. It is in fine acicular crystals of a bright yellow color and intensely bitter taste, very slightly soluble in cold water, to which, however, it imparts a deep yellow color, slightly soluble also in cold alcohol, but dissolved in large proportion by both liquids when hot. By concentrated nitric acid both this salt and its base are decomposed, with the production of a dark red color and the escape of nitrous fumes. A process for *berberine hypophosphite*, by Prof. J. U. Lloyd, may be found in *A. J. P.*, July, 1877. Parsons (*N. R.*, 1879, 109) analyzed *berberine phosphate*, and believes the formula to be $C_{20}H_{17}NO_4,2H_3PO_4$.

According to the studies of Falck and Guenste, berberine causes in dogs and rabbits restlessness, convulsive tremblings, hurried respiration, and diarrhœa, followed, if the dose have been large enough, by decrease of the breathing-rate, wide-spread paralysis, dyspnœa, convulsions, and death. In man as yet no serious symptoms have been recorded as produced by it. Buchner is stated to have taken nearly twenty grains without causing anything more serious than a loose stool. It has been employed in internal medicine as a simple bitter, in doses of from two to five grains (0·13–0·33 Gm.).

don, is due the credit of having fully investigated the properties of this alkaloid.* Hydrastine crystallizes in brilliant, four-sided prisms, which are white or colorless when pure, inodorous, and almost tasteless in consequence of their insolubility in the saliva, but become bitter and somewhat acrid in saline combination. It melts at 132° C. (269·6° F.), is decomposed at a higher temperature, and is inflammable. It is nearly insoluble in water, but is readily dissolved by alcohol, ether, chloroform, and benzol. It has an alkaline reaction, and with the acids forms salts, most of which are readily soluble in water, and, according to Mr. Merrill, of Cincinnati, either uncrystallizable or crystallizable with difficulty. The alkalies and tannic acid precipitate it from its saline solutions. With sulphuric acid and potassium bichromate or red lead oxide, it assumes a red color; but it differs from strychnine in exhibiting no tint of blue or violet. Its composition is $C_{21}H_{21}NO_6$. Mr. Perrins obtained 1·5 per cent. of it from the root, and, having given five grains of it to a rabbit without any other effect than a slight uneasiness which soon ceased, concluded justly that it was not poisonous.

Canadine ($C_{20}H_{21}NO_4$) was extracted by E. Schmidt; it occurs in the form of brilliant, small, white nodules, melting at 134° C. (273·2° F.). When canadine is dissolved in alcohol and treated with iodine, berberine iodohydrate (which is yellow in color) is formed. Canadine was believed to be identical with dihydromethylberberine (*Pharm. Post*, 1892, 230), and the formula $C_{21}H_{21}NO_4$ was given to it. E. Schmidt, however (*Archiv der Pharm.*, 1894, 136–154), has found that its true formula is $C_{20}H_{21}NO_4$, and, owing to the fact that iodine forms with it berberine hydriodate, he believes that canadine is a tetrahydroberberine. Schmidt also obtained, as an additional product of the iodine reaction, the hydriodate of another base, which he believes is intermediate between berberine and canadine. For a process for isolating canadine, see *Proc. A. P. A.*, 1894, 1103. The alkaloid discovered by A. K. Hale, and obtained later by Burt and by Lerchen, and which was named *xanthopuccine*, is now considered to be identical with canadine. For processes for making hydrastine and berberine, see *Drug. Circ.*, 1897, 34.† It is probable, from the odor of hydrastis, that besides the two alkaloids here mentioned it contains also an active volatile principle; but this has not yet been isolated.

Medical Properties and Uses. As a local remedy hydrastis has a remarkable effect upon mucous membranes. It has been used with asserted remarkable results in chronic *gastro-intestinal catarrhs*, especially those due to alcoholic excess, and as the commercial hydrastin is one of the drugs that was found in the experiments of Professor Rutherford to notably increase the biliary secretion in the lower animals, it is probable that in gastric diseases attended by *hepatic congestion* and lack of functional activity it exerts an almost specific influence. It has been strongly recommended in *dyspepsia* and the *vomiting of pregnancy*. It is much used by specialists as a local remedy in the treatment of *otorrhœa*, *nasal*, *vaginal*, and other *catarrhs*. In the second stage of *gonorrhœa*, as an addition to injection mixtures, it may be of great service. In chronic or subacute *inflammations* of the *colon* and *rectum* injections of hydrastis are often of great service, and it has been used in *hemorrhoids* with asserted excellent results.

The strength of the local application of hydrastis to be used in various diseases of the mucous membranes varies from half a fluidrachm to two drachms of the fluid extract to the ounce of diluent. In *gonorrhœa* from five to ten grains of hydrastin, or forty to eighty minims of the fluid extract, may be used to the fluidounce. In *hemorrhoids* from two to four drachms to the fluidounce may be used. The glycerite is not so useful a local preparation as the fluid extract diluted with water, a deposit of the insoluble resinous substance upon the mucous membrane and its constant prolonged influence being important.

The general action of hydrastis upon the system is probably chiefly due to its hydrastine, which is absorbed somewhat slowly from the alimentary canal and is eliminated through the

* Wilhelm (*P. J. Tr.*, 1888, 325) furnishes a process for obtaining the alkaloids from hydrastis as follows. The extract obtained by treating the coarsely powdered root with water acidified with acetic acid at 100° is evaporated to a syrup and excess of dilute sulphuric acid added, when berberine sulphate separates. The filtrate neutralized with ammonia gives a precipitate containing much hydrastine; this is separated, and on adding ammonia in excess to the filtrate a further precipitate is produced, which contains *canadine*. Both precipitates, boiled with ethyl acetate, give solutions which on cooling deposit hydrastine in large crystals, somewhat colored, but rendered pure by recrystallization. The crystals from the second ammonia precipitate are much purer than those from the first; by slow evaporation of the ethyl acetate solution they can be obtained as large as walnuts.

Hydroberberine, whose molecule contains four atoms of hydrogen more than the molecule of berberine, is said by Dr. Marfori to differ from berberine physiologically; it produces in moderate dose an increase in the blood-pressure by stimulating the vaso-motor centre in the medulla. *Opianic*, *hydrastinic*, *and berberinic acids* are said by the same authority to be almost inert physiologically, except that they are feebly antiseptic. (*Therap. Gaz.*, 1890.)

† For a physiological study of the *methylamine* derivatives of hydrastine (*hydrastine methylamine*), see *Virchow's Archiv*, cxlii., 1895.

kidneys, and also probably through the lower bowel, unchanged. In the physiological laboratory hydrastine has been found to increase reflex activity and to produce tetanic contractions by primarily stimulating the motor side of the spinal cord. If the dose have been sufficient the period of motor activity is followed by one of depression, in which the loss of reflex power and the paralysis are probably in part due to depression of the motor centres, and are certainly, at least in part, the outcome of depression of the motor nerves and also of the muscles themselves. According to Cerna, the first loss of reflex activity is due to stimulation of Setschenow's centre, and the final muscular depression is preceded by excitation of the muscle-fibres. Death may occur in a convulsion from cramp-asphyxia, or later from simultaneous paralysis of the respiratory centres and of the peripheral apparatus. The arterial pressure is first elevated and secondarily depressed; the first rise of pressure is probably due to the stimulation of the heart-muscles, increasing the output of force, and also of both the vaso-motor centres and the muscle-fibres in the arteriole coats, causing contraction of the blood-vessels. The fall of pressure is probably the result of a direct paralytic action exerted upon the muscle-fibres in the heart and in the arterioles. Hydrastine notably increases intestinal peristalsis, and probably uterine contractions. It would seem to be a universal muscle-poison, which acts upon both striated and non-striated muscle-fibre in heart, arterioles, intestines, uterus, and generally throughout the body, its first stimulant action upon the muscle-fibres being followed by marked depression.

Both Fellner and Slavatinski affirm that hydrastine has a distinct ecbolic action, causing uterine contractions in the non-pregnant uterus, and abortion in pregnant rabbits. Dr. Slavatinski reports a case of premature labor produced by hypodermic injections of from two to three grammes repeated daily. These assertions are confirmed by the experiments of Tarachanow, who found that when hydrastine was given to the narcotized, recently pregnant animal, energetic contractions of the exposed uterus were produced. Total section of the uterine nerves prevented these contractions, which would seem, therefore, to be of centric origin.

It is essential to recognize the non-identity, medically, of the preparations of hydrastis. The so-called *hydrastin of commerce* is really an impure body, containing berberine, canadine, hydrastine, and probably some resin. It is this mixture which Prof. Rutherford found to have a pronounced influence upon the biliary secretion in the lower animals. Whether this action be or be not dependent upon the presence of berberine or other impurities is as yet uncertain. The practical deduction is, however, that when hydrastis is to be used in chronic gastro-intestinal catarrh, or as a local application to mucous membranes, it is better to use hydrastin or the fluid extract rather than the pure alkaloid. The dose of hydrastin is from five to ten grains.

There is some reason for believing that *berberine* has a special action upon the gastro-intestinal tract. Marfori has, however, found that even in large therapeutic dose it is without perceptible influence upon the circulation or the nervous system. When, therefore, a preparation of hydrastis is to be used for effects other than a local action on the gastro-intestinal or other mucous membranes, the pure alkaloid hydrastine should be used. There is abundant clinical testimony to the great value of hydrastine in the treatment of *uterine hemorrhages*, whether occurring in the non-parturient or in the parturient woman. The dose of hydrastine, or of its salts, is from one-eighth to one-half of a grain (0·008–0·032 Gm.).*

HYOSCINÆ HYDROBROMAS. U. S. (Br.) Hyoscine Hydrobromate.

(HĪ-ŌS-CĪ′NÆ HĪ-DRŌ-BRŌ′MĂS.)

$C_{17}H_{21}NO_4HBr.3H_2O$; 436·98.

"The hydrobromate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials." *U. S.* "The hydrobromide, $C_{17}H_{21}NO_4.HBr,3H_2O$, of an alkaloid contained in Hyoscyamus Leaves, different species of Scopola, and possibly other solanaceous plants." *Br.*

Hyoscinæ Hydrobromidum, *Br.*, Hyoscine Hydrobromide; Hydrobromate of Hyoscine, Scopolamine Hydrobromide.

This salt was introduced for the first time in the U. S. P. 1890. *Hyoscine*, $C_{17}H_{21}NO_4$, is found in the leaves and seeds of Hyoscyamus, and the amorphous hyoscyamine of commerce

* *Liquor Hydrastinæ.* Under the names of *Liquid Hydrastis*, *Fluid Hydrastis*, *Colorless Hydrastis*, etc., preparations of the alkaloids of hydrastis have been largely used. In some cases these solutions have been made directly from the drug by depriving a fluid extract of coloring matter, in others the alkaloid has been dissolved in a suitable liquid. Gust. Steinmann (*A. J. P.*, 1887, 296) examined several samples and found hydrastine in each, combined with either sulphuric or hydrochloric acid, besides aluminum, potassium, boric acid, etc., in small proportion; by dissolving 20 grains of hydrastine sulphate or chloride in a pint of a solution of glycerin and water (sp. gr. 1·15), a liquid is produced from which the asserted good results can be obtained.

appears in most cases to be hyoscine, and to be more powerful than the crystallized hyoscyamine itself. Pure hyoscine forms a syrupy liquid. The best salt for practical use is the hydrobromate, which is in "colorless, transparent, rhombic crystals, odorless, and having an acrid, slightly bitter taste; permanent in the air. Soluble, at 15° C. (59° F.), in 1·9 parts of water, and in 13 parts of alcohol; very slightly soluble in ether or chloroform. When heated to 100° C. (212° F.), the salt loses its water of crystallization, and fuses to a thick, syrupy mass, which becomes quite fluid at 160° C. (320° F.). When ignited, it is consumed, leaving no residue. The salt is neutral to litmus paper. Addition of ammonia water to the aqueous solution of the salt (1 in 60) produces no change, but sodium or potassium hydrate test-solution causes a white turbidity. Addition of silver nitrate test-solution to the aqueous solution produces a yellowish-white precipitate, which is insoluble in nitric acid; but, when filtered off and washed, is soluble in ammonia water diluted with its own volume of water. If 5 drops of fuming nitric acid be added to 0·01 Gm. of the salt, in a small porcelain capsule, and the mixture be evaporated to dryness on a water-bath, a scarcely tinted residue will be left, which, when treated, after cooling, with a few drops of an alcoholic solution of potassium hydrate, will assume a violet color." *U. S.* "It has an acrid, slightly bitter taste, and is odorless. It is soluble in 1 part of cold *water* and in 13 parts of *alcohol* (90 per cent.), very slightly soluble in *ether* or *chloroform*. When heated to 212° F. (100° C.) it loses rather more than 12 per cent. of its weight and fuses to a viscid mass which becomes liquid at a temperature of 379·4° to 381·2° F. (193° to 194° C.). An aqueous solution yields a precipitate with *test-solution of mercuric chloride, solution of iodine*, or *solution of potassium hydroxide*, but not with *solution of ammonia* or *solution of potassium bichromate*. It forms with *auric chloride* a crystalline salt having a melting point of 388·4° F. (198° C.). It affords the reactions characteristic of hydrobromides. Its aqueous solution slightly reddens *litmus*. Heated to redness with access of air it leaves no residue." *Br.*

Prof. E. Schmidt (*Apoth. Zeit.*, 1891, 522) believes that the hyoscine hydrobromate of commerce is essentially hydrobromate of *scopolamine*, $C_{17}H_{21}NO_4$. This view has been confirmed by O. Hesse (*Ann. d. Chem.*, 1893, 304), and the British Pharmacopœia defines hyoscine as an alkaloid contained in hyoscyamus, different species of Scopola, and possibly other solanaceous plants, while the committee of revision of the German Pharmacopœia recommends the change of the official title of "Hyoscin Hydrobromate" to "Scopolamium Hydrobromium." *Atroscine* was found by Hesse in variable amount in the hyoscine hydrobromide of commerce. It is a mydriatic equal in power to atropine or scopolamine. *Scopolamine hydrochloride* occurs in beautiful glassy crystals, 3 Cm. long and 2 Cm. broad.

Medical Properties and Uses. Various observers have noted that the impure amorphous hyoscyamine is more powerful than the crystallized alkaloid. These observations, with the chemical fact that amorphous hyoscyamine is chiefly hyoscine, in 1884 led Dr. H. C. Wood to make a careful physiological study of that alkaloid upon the lower animals and to apply it to clinical medicine. It was found that the pure hyoscine produced in the frog motor reflex paralysis, due to a depression of the spinal cord, and that in mammals it caused disturbance of respiration, loss of muscular power, pronounced tendency to stupor, and, finally, death by asphyxia. It exerted very little influence upon the circulation even when in toxic doses. It became evident that the drug was a depressant of the principal cerebral centres, of the respiratory centres, and also of the lower motor centres of the spinal cord. In man, the ingestion of hyoscine in decided doses is followed in a very short time by dryness of the mouth, flushings of the face, great sleepiness, associated in some cases with delirious mutterings, and giddiness akin to that of alcoholic intoxication. The respirations are usually lessened in frequency, and the pulse-rate is also somewhat diminished. Dilatation of the pupils is usually, but not invariably, produced. After toxic doses these symptoms are intensified; whilst the frequent loss or impairment of the power of swallowing, and a peculiar hoarseness of the voice, with, in some cases, laryngeal dyspnœa, indicate that the muscles of the larynx, as well as those of the pharynx, have a special tendency to be paralyzed by the alkaloid; the respiration not only becomes slow and full, but sometimes takes on a distinctly Cheyne-Stokes character; the skin is not dry, as in atropine-poisoning, but is frequently covered with sweat. No cases of fatal poisoning are on record. One-fourth of a grain of very impure hyoscine produced in the case of Dr. Hutchinson profound muscular relaxation, with quiet coma lasting for eleven hours. In applying hyoscine to the treatment of disease, Dr. H. C. Wood found that it is a valuable soporific, especially useful in those cases in which the wakefulness is complicated with or due to cerebral excitement. In *insomnia* produced by overwork, when the brain seems to lose the capability of ceasing its action, hyoscine is of service; but it is especially valuable in active delirious con-

ditions, such as occur in *acute mania* or in exacerbations in the course of *chronic mania*. In those cases in which morphine increases the cerebral excitement hyoscine usually acts most happily. According to the statements of Drs. Bruce and Tirard, it is an entirely safe remedy in cases of severe kidney disease when morphine is contra-indicated. Dr. H. C. Wood has found that it is an efficient remedy in the treatment of sexual excitement, such as *nymphomania*, *spermatorrhœa*, and allied affections, and that it will almost invariably control *excessive seminal emissions*. Hyoscine rarely, if ever, produces much more serious after-effects than a little dryness of the throat and headache, and does not disturb the alimentary canal. The reports of later clinicians indicate that excessive susceptibility to its influence is a not infrequent idiosyncrasy, and it is even affirmed that $\frac{1}{200}$ of a grain has caused alarming symptoms. It is probable, however, that much larger doses were taken in these cases than is alleged. On account of its tendency to produce pharyngeal and laryngeal paralysis, it should not be employed in such diseases as scarlet fever or diphtheria when there is a tendency to throat difficulties. Being practically tasteless, hyoscine is readily given in food or drink without the knowledge of the patient. It acts well when taken by the mouth, but is especially efficient and prompt when administered hypodermically, and never produces local irritation. The effects of a hypodermic dose are usually manifested inside of ten minutes, and persist for six or eight hours. The dose by the mouth is from $\frac{1}{120}$ to $\frac{1}{60}$ of a grain; for hypodermic injections $\frac{1}{150}$ to $\frac{1}{100}$ of a grain. On account of the susceptibility of some persons to it, the commencing dose by the mouth should not be over $\frac{1}{120}$ of a grain, by injection $\frac{1}{150}$ of a grain: after cautious trial, doses larger than the maximum just given may be employed.

HYOSCYAMINÆ HYDROBROMAS. U. S. Hyoscyamine Hydrobromate.

$C_{17}H_{23}NO_3HBr$; 369·14. (HĪ-ŌS-CĪ-Ą-MĪ'NÆ HĪ-DRŌ-BRŌ'MĂS.)

"The hydrobromate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials." *U. S.*

There seems to have been little necessity for the introduction of this salt into the U. S. P. 1890, particularly since hyoscyamine sulphate has been retained. It is officially described as "a yellowish-white, amorphous, resin-like mass, or prismatic crystals, having, particularly when damp, a tobacco-like odor, and an acrid, nauseous, and bitter taste; deliquescent on exposure to air. Soluble, at 15° C. (59° F.), in about 0·3 part of water, 2 parts of alcohol, 3000 parts of ether, or 250 parts of chloroform. At 78° C. (172·4° F.) the salt melts, forming a nearly colorless liquid. When ignited, it is consumed, leaving no residue. The salt is neutral to litmus paper. An aqueous solution of the salt is not precipitated by platinic chloride test-solution (difference from *most other alkaloids*). With gold chloride test-solution it yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (difference from *atropine*). The aqueous solution of the salt yields, with silver nitrate test-solution, a yellowish-white precipitate, which is insoluble in nitric acid; but, when filtered off and washed, is soluble in ammonia water diluted with its own volume of water." *U. S.*

The medical properties and the dose of this salt of hyoscyamine are precisely those of the sulphate, to which it is preferred by some.

HYOSCYAMINÆ SULPHAS. U. S., Br. Hyoscyamine Sulphate.

$(C_{17}H_{23}NO_3)_2H_2SO_4$; 674·58. (HĪ-ŌS-CĪ-Ą-MĪ'NÆ SŪL'PHĂS.) $(C_{17}H_{23}NO_3)_2.H_2SO_4$: 676.

"The neutral sulphate of an alkaloid obtained from Hyoscyamus. It should be kept in small, well-stoppered vials." *U. S.* "The sulphate, $(C_{17}H_{23}NO_3)_2.H_2SO_4.2H_2O$, of an alkaloid contained in Hyoscyamus Leaves and possibly other solanaceous plants." *Br.*

Sulfate d'Hyoscyamine, *Fr.*; Hyoscyaminum Sulfuricum, Schwefelsaures Hyoscyamin, *G.*

Although Brandes announced the existence of an alkaloid in the seeds of *Hyoscyamus niger*, the process which he used to obtain it was not successful in other hands. The credit of first isolating the alkaloid *hyoscyamine* or *hyoscyamia* from the plant must be given to Geiger and Hesse, who obtained it as long ago as 1833. Höhn and Reichardt's process, in which the seed is used as the source, is as follows. They treat hyoscyamus seed first with ether to separate fatty matter, then with alcohol acidulated with a few drops of sulphuric acid, and afterwards distil the alcoholic solution. The aqueous residue is to be neutralized by soda, and the liquid precipitated by a solution of tannin. The precipitate, having been placed on a porcelain plate to dry, is mixed while yet moist with an excess of lime, and then exhausted by strong alcohol.

The alcoholic solution is treated with sulphuric acid, then with soda, and finally with ether, which dissolves the liberated hyoscyamine. By distilling off the ether a colorless oleaginous liquid is left, which at length concretes. (*Journ. de Pharm.*, Mai, 1872, p. 385.)

These investigators gave to hyoscyamine the formula $C_{15}H_{23}NO_3$, but Ladenburg has shown by a study of its decomposition products that it is isomeric with atropine, $C_{17}H_{23}NO_3$. Ladenburg made the most complete study of atropine and hyoscyamine that we have, and has established their relations to each other in a clearer light. According to him (*Ber. der Chem. Ges.*, xiii., pp. 251, 909, and 1549), hyoscyamus contains two alkaloids, a crystalline one, to which the name of *hyoscyamine* is given, and which is the one hitherto studied under that name, and an amorphous one, which remains in the mother-liquor after the removal of the crystallizable alkaloid, and comes into commerce as a brown thickish syrup. It can be extracted by the formation of the gold salt, which is less soluble than hyoscyamine gold chloride. This alkaloid, for which he proposed the name *hyoscine*, and to which he gave the same formula ($C_{17}H_{23}NO_3$) as hyoscyamine, yields different decomposition products upon decomposition by baryta water. Hyoscyamine treated with boiling baryta water assimilates a molecule of water and splits up into what were called *hyoscinic acid*, $C_9H_{10}O_3$, and *hyoscine*, $C_8H_{15}NO$, but which Ladenburg shows to be simply identical with the decomposition products of atropine, *tropic acid* and *tropine*. The non-existence of Ladenburg's hyoscine of the formula $C_{17}H_{23}NO_3$ and the truth of the statement that commercial hyoscine is identical with scopolamine (see p. 719) is strongly supported upon large experience in manufacturing these bases by Dr. L. Merck. Inasmuch as Ladenburg (*Ber. der Chem. Ges.*, xii. 941) has succeeded in effecting the synthesis of *atropine* by the combination of tropic acid and tropine (the two decomposition products which are common to the two alkaloids *atropine* and *hyoscyamine*), we must look for the differences between these two to physical and molecular sources rather than chemical.

Hyoscyamine crystallizes in colorless, transparent, silky needles, fusing at 108·5° C., is inodorous, of an acrid, disagreeable taste, slightly soluble in water, very soluble in alcohol and ether, and volatilizable with little change if carefully distilled. It is quickly altered by contact with water and an alkali, and when heated with potassa or soda is completely decomposed, with the disengagement of ammonia. It neutralizes the acids, forming crystallizable salts,* and is precipitated by infusion of galls. The alkaloid and its salts are very poisonous; and the smallest quantity, introduced into the eye, produces dilatation of the pupil, which continues long.

Hyoscine has been known in commerce as *amorphous hyoscyamine*. The best salts, according to Prof. Edlefsen, to prepare and dispense are the *hydrobromate* and *hydriodate*. Hyoscine hydriodate crystallizes from water, in which it is only moderately soluble, in small, hemihedral prisms, which mostly have a slight yellowish color. (See *Hyoscinæ Hydrobromas.*)

The double gold chloride, $C_{17}H_{21}NO_4HCl + AuCl_3$, is less soluble than the corresponding gold salt of hyoscyamine, and so serves to separate them when together.

Properties. The Pharmacopœia describes the sulphate of hyoscyamine as "white, indistinct crystals, or a white powder, without odor, and having a bitter, acrid taste; deliquescent in damp air. Soluble, at 15° C. (59° F.), in 0·5 part of water, and in 2·5 parts of alcohol; very slightly soluble in ether or chloroform. At 140° to 160° C. (284° to 320° F.) the salt melts, and, upon ignition, is consumed, leaving no residue. The salt is neutral to litmus paper. An aqueous solution of the salt is not precipitated by platinic chloride test-solution (difference from *most other alkaloids*). With gold chloride test-solution it yields a precipitate which, when recrystallized from a small quantity of boiling water acidulated with hydrochloric acid, is deposited, on cooling, in minute, lustrous, golden-yellow scales (difference from *atropine*). The aqueous solution of the salt yields, with barium chloride test-solution, a white precipitate insoluble in hydrochloric acid." *U. S.* "A crystalline powder, deliquescent, odorless, having a bitter acrid taste. Melting point 402·8° F. (206° C.). Soluble in 0·5 part of *water*, 2·5 parts of *alcohol* (90 per cent.), very slightly soluble in *ether* or *chloroform*. It affords the reactions characteristic of sulphates. A solution in *water* acidulated with *hydrochloric acid* yields no precipitate with *solution of platinic chloride*, but affords with *solution of auric chloride* a yellow precipitate soluble in boiling *water* acidulated with *hydrochloric acid*, and again deposited, as the solution cools, in brilliant, golden-yellow scales (distinction from atropine). Heated to redness with access of air it leaves no residue." *Br.*

* According to the latest chemical researches (see *Belladonnæ Radix*, p. 261), duboisine is the same as hyoscyamine: the symptoms which have been reported in cases of poisoning by duboisine are very similar to those which occur in atropine-poisoning, save only in the apparent presence of excessive muscular weakness and in the slowness of the pulse which has been noted by a number of observers. For abstracts of reported cases of poisoning by duboisine, see 16th ed. U. S. D., p. 288.

Medical Properties. Owing to the facts that until very recently commercial hyoscyamine has usually been contaminated with hyoscine, and that few careful studies of a chemically pure hyoscyamine have been made, its exact influence upon the human system is not positively determined. The studies of Dr. J. C. Shaw appear, however, to prove that hyoscyamine acts upon the nervous system and the circulation, including the heart and the vaso-motor system, precisely as does atropine, except as regards respiration, which appears in most cases to have been slowed rather than increased in rapidity, an indication that hyoscyamine, unlike atropine, is not a respiratory stimulant. Dr. Shaw also found that hyoscyamine is less powerful as a mydriatic and more powerful as a soporific than is atropine. On the other hand, in studies upon normal men, Dr. Richter could not perceive that hyoscyamine had a tendency to produce sleep. Prof. Sydney Ringer, in a careful comparative study of hyoscyamine and atropine in acute mania, was unable to detect any important differences in the action of the two substances. The dose of commercial hyoscyamine varies greatly according to its purity, but one-fortieth of a grain of the pure alkaloid has produced violent poisoning, with symptoms similar to those caused by atropine: not more than one-eighteenth of a grain (0·0008 Gm.) should be given as a commencing dose.

HYOSCYAMUS. U. S. (Br.) Hyoscyamus. [Henbane.]

(HĬ-ǪS-CĬ'Ą-MŬS.)

"The leaves and flowering tops of Hyoscyamus niger, Linné (nat. ord. Solanaceæ), collected from plants of the second year's growth." *U. S.* "The fresh leaves and flowers, with the branches to which they are attached, of Hyoscyamus niger, Linn.; also the leaves and the flowering tops, separated from the branches and carefully dried. Collected from the flowering biennial plants." *Br.*

Hyoscyami Folia, *Br.;* Herba Hyoscyami; Feuilles de Jusquiame noire, *Fr.;* Bilsenkraut, *G.*

There are about eleven species of the genus Hyoscyamus known; these are distributed from the Canary Islands over Europe and Northern Africa to Asia.

Epithelium of Hyoscyamus leaf, showing stoma and hair.

Hyoscyamus niger. L. *Sp. Pl.* (1753) 179; Willd. *Sp. Plant.* i. 1010; Woodv. *Med. Bot.*, 204, t. 76; Carson, *Illust. of Med. Bot.*, ii. 19, pl. 66. Henbane is usually a biennial plant, with a long, tapering, whitish, fleshy, somewhat branching root, not unlike that of parsley, for which it has been eaten by mistake, with poisonous effects. The stem, which rises in the second year, is erect, round, branching, from one to four feet high, and thickly furnished with leaves. These are large, oblong-ovate, deeply sinuated with pointed segments, undulated, soft to the touch, and at their base embrace the stem. The upper leaves are generally entire. Both the stem and leaves are hairy, viscid, and of a sea-green color. The flowers form long, one-sided, leafy spikes, which terminate the branches, and hang downward. They are composed of a calyx with five pointed divisions, a funnel-shaped corolla, with five unequal, obtuse segments at the border, five stamens inserted into the tube of the corolla, and a pistil with a blunt, round stigma. The corolla is of an obscure yellow color, beautifully variegated with purple veins. The fruit is a globular two-celled capsule, covered with a lid, invested with the persistent calyx, and containing numerous small seeds, which are discharged by the horizontal separation of the lid. The whole plant has a rank, offensive odor.

H. niger is susceptible of considerable diversity of character, causing varieties which have by some been considered as distinct species. Thus, the plant is sometimes annual, the stem simple, smaller, and less downy than in the biennial plant, the leaves shorter and less hairy and viscid, and the flowers often yellow without the purple streaks. It has been ascertained that much difference of medical properties is connected with these diversities of character; and the British Pharmacopœia directs the biennial variety as the most efficient.

The plant is found in the northern and eastern sections of the United States, occupying waste grounds in the older settlements, particularly graveyards, old gardens, and the foundations of ruined houses. It grows in great abundance about Detroit, in Michigan. It is not, however, a native of this country, having been intro-

duced from Europe. In Great Britain, and on the continent of Europe, it grows abundantly along the roads, around villages, amidst rubbish, and in uncultivated places. Both varieties were formerly cultivated in England, but at present the biennial is chiefly or solely grown. The annual plant flowers in July or August, the biennial in May or June. For an account of the cultivation of the biennial variety at Hitchin, England, see *P. J. Tr.*, Feb. 1860.

H. albus, so named from the whiteness of its flowers, is used in France indiscriminately with the former species, with which it appears to be identical in medicinal properties.

All parts of *Hyoscyamus niger* are active. The official description of the plant is as follows: "Leaves ovate, or ovate-oblong, up to 25 Cm. long and 10 Cm. broad; sinuate-toothed, the teeth large, oblong or triangular; grayish-green, and, particularly on the lower surface, glandular-hairy; midrib prominent; flowers nearly sessile, with an urn-shaped, five-toothed calyx, and a light yellow, purple-veined corolla; odor heavy, narcotic; taste bitter and somewhat acrid." *U. S.* The mesophyll of the leaf contains small prisms of calcium oxalate. Much of the efficacy of henbane depends upon the time at which it is gathered. The leaves should be collected soon after the plant has flowered. In the biennial plant, those of the second year are preferred to those of the first. The latter, according to Dr. Houlton, are less clammy and fetid, yield less extractive, and are medicinally much less efficient. It is said that the plant is sometimes destroyed by severe winters in England, and that no leaves of the second year's growth are then obtainable. This is, perhaps, one of the causes of the great uncertainty of the medicine as found in commerce. The root also is said to be much more poisonous in the second year than in the first.*

Properties. The recent leaves have, when bruised, a strong, disagreeable, narcotic odor, somewhat like that of tobacco. Their taste is mucilaginous and very slightly acrid. When dried, they have little smell or taste. Thrown upon the fire, they burn with a crackling noise, as if they contained a nitrate, and at the same time emit a strong odor. Their virtues are completely extracted by diluted alcohol. The aqueous infusion is of a pale-yellow color, insipid, with the narcotic odor of the plant. The leaves were analyzed by Lindbergsen, who obtained from them a narcotic principle. They contain a large proportion of potassium nitrate, Mr. F. Mahla having obtained, as nearly as he could estimate from his experiments, 2 per cent. of that salt. (*A. J. P.*, 1859, p. 402.) The seeds are very small, roundish, compressed, somewhat kidney-shaped, a little wrinkled, of a gray or yellowish-gray color, of the odor of the plant, and of an oleaginous, bitterish taste. Geiger and Hesse (1833) were the first to demonstrate the existence of an alkaloid in hyoscyamus. Ladenburg has shown (1880) that there are two alkaloids in the plant,—one crystallizable, *hyoscyamine*, and the other amorphous, *hyoscine* (scopolamine, p. 719). (See *Hyoscyaminæ Sulphas*, p. 720, and *Hyoscinæ Hydrobromas*, p. 718.) Höhn (*Ann. Chem. Pharm.*, 157, 98) obtained from the seeds a bitter principle which proved to be a glucoside. He calls it *hyoscypicrin*, and gives it the formula $C_{27}H_{52}O_{14}$.

From experiments made by Mr. Hirtz upon the relative medicinal power of extracts from the seeds and from the leaves, he inferred that the former had ten times the strength of the latter. Henbane leaves yield, by destructive distillation, a very poisonous empyreumatic oil.

Medical Properties and Uses. Hyoscyamus was known to the ancients, and was employed by some of the earlier modern practitioners, but had fallen into disuse, and was almost forgotten, when Baron Störck again introduced it into notice. By this physician and some of his successors it was prescribed in numerous diseases, and, if we may credit their testimony, with the happiest effects; but subsequent experience of its operation has greatly narrowed the extent of its application. It is at present used almost exclusively to relieve pain, procure sleep, or quiet irregular nervous action, and is not supposed to exercise any specific curative influence over particular diseases. It is similar in its physiological action to belladonna, and in poisonous doses produces similar symptoms, but it is more of a hypnotic and much feebler. It is chiefly employed to allay nervous irritation, in *hysteria*, and in various pectoral diseases with *cough*, also to prevent griping by the vegetable cathartics. In Europe, where the fresh leaves

* The several products of the henbane plants are placed by Mr. R. Usher (*P. J. Tr.*, Aug. 1867) in the following order, as to efficiency: 1, the leaves of the biennial plant of the second year's growth; 2, the biennial plant of the first year; 3, the British annual henbane; 4, the German annual henbane. The last two, though most extensively used, are really nearly valueless, and should always be rejected. The British annual so nearly resembles the biennial of the second year, having flowers, that the two may be easily mistaken for each other; but a sufficient distinction is that the annual plant "possesses no flavor or aroma." Besides, the leaves are much shorter; and occasionally there is a pure primrose blossom, which never happens with the biennial, which is beautifully streaked. The biennial plant is so liable to the attacks of worms that at one time little of the second year's growth was collected, and the market was consequently supplied with a very inferior article.

are readily obtained, it is often applied externally in the shape of lotion, cataplasm, or fomentation, to allay pain and irritation, in *scrofulous* or *cancerous ulcers*, *scirrhous*, *hemorrhoidal*, or other painful *tumors*, *gouty* and *rheumatic swellings*, and *nervous headaches*. The treatment of hyoscyamus-poisoning is identical with that of belladonna-poisoning. (See *Belladonna*.)

Henbane may be given in fluid or solid extract or in tincture. The dose of the leaves is from five to ten grains (0·33–0·65 Gm.), that of the seeds somewhat smaller. The extract, or inspissated juice of the fresh leaves (*Extractum Hyoscyami Viride*, *Br.*), is exceedingly variable in its operation, being sometimes active, sometimes almost inert. The usual dose is from two to three grains (0·13–0·20 Gm.), repeated and gradually increased till its effects are obtained. The alcoholic extract (*Extractum Hyoscyami*, *U. S.*) is more certain. Dose, from one to two grains (0·065–0·13 Gm.), increased *pro re nata*. An extract from the seeds would be more efficacious. Dose of the tincture, from one to two fluidrachms (3·75–7·5 C.c.).

ICHTHYOCOLLA. U. S. Isinglass.

(ĬĈH-THY-Ọ-CŎL'LĄ.)

"The swimming-bladder of Acipenser Huso, Linné, and of other species of Acipenser (class, Pisces; order, Sturiones)." *U. S.*

Colla Piscium, *P. G.;* Fish-Glue; Ichthyocolle, Colle de Poisson, *Fr.;* Hausenblase, Fischleim, *G.;* Colla di Pesce, *It.;* Cola de Pescado, *Sp.*

Isinglass is a gelatinous substance, prepared chiefly from the sounds or swimming-bladders of fishes, especially those of different species of sturgeon. In most fishes there is a membranous bag, placed in the anterior part of the abdomen, communicating frequently, though not always, by means of a duct, with the œsophagus or stomach, and containing usually a mixture of oxygen and nitrogen gases in various proportions. From the supposition that it was intended by its expansion or contraction to enable the fish to rise or sink in the water, it has been termed the *swimming-bladder*. It is of different shape in different fishes, and consists of three coats, of which the two interior are thin and delicate, the outer tough and of a silvery whiteness.

The *Acipenser huso*, or *beluga* of the Russians, is particularly designated by the Pharmacopœia as the species of sturgeon from which isinglass is procured; but three others, *A. ruthenus*, or sterlet, *A. sturio*, or common sturgeon, and *A. stellatus*, or starred sturgeon, also furnish large quantities to commerce. All these fish inhabit the interior waters of Russia, especially the Volga and other streams which empty into the Caspian Sea. Immense numbers are annually taken, and consumed as food by the Russians. The air-bags are removed from the fish, and, having been split open and washed in water in order to separate the blood, fat, and adhering extraneous membranes, are spread out, and when sufficiently stiffened are formed into cylindrical rolls, the ends of which are brought together and secured by pegs. The shape given to the roll is that of a staple, or more accurately that of a lyre, which it firmly retains when dried. Thus prepared it is known in commerce by the name of *staple isinglass*, and is distinguished into the *long* and the *short staple*. Sometimes the membranes are dried in a flat state, or simply folded, and then receive the name of *leaf* or *book isinglass*. The scraps or fragments of these varieties, with various other parts of the fish, are boiled in water, which dissolves the gelatin, and upon evaporation leaves it in a solid state. This is called *cake isinglass*, from the shape which it is made to assume. It is sometimes, however, in globular masses. Of these varieties, the *long staple* is said to be the best; but the finest *book isinglass* is not surpassed by any brought to this country. It is remarkable for its beautiful iridescence by transmitted light. One hundred grains of this isinglass dissolve in ten ounces of water, forming a tremulous jelly when cold, and yield but two grains of insoluble residuum. That in *cakes* is brownish, of an unpleasant odor, and employed only in the arts. Inferior kinds, with the same commercial titles, are said to be prepared from the peritoneum and intestines of the fish. An inferior Russian product, known in English commerce by the name of *Samovey isinglass*, is procured, according to Pereira, from the *Silurus glanis*. It comes, like the better kind, in the shape of *leaf*, *book*, and the *short staple*. Isinglass, little inferior to the Russian, is made in Iceland from the sounds of the cod and ling. It is said also to be prepared by the fishermen of Newfoundland. We receive from Brazil the air-bladders of a large fish, prepared by drying them in their distended state. They are oblong, tapering, and pointed at one end, bifid with the remains of their pneumatic duct at the other, and of a firm consistence. The Brazilian isinglass is inferior to the Russian. Considerable quantities are manufactured in New England. This sort (*American isinglass*) is in thin ribbons several feet in length, and from an inch and a half to two inches in width. One hundred grains dissolve almost entirely in water,

leaving but two grains of insoluble membrane, and form a jelly when cold with eight ounces of water. It is, therefore, as pure and nearly as strong a gelatin as the Russian isinglass; but it retains a fishy taste and odor, which render it unfit for culinary or medicinal purposes. Isinglass of good quality has also been made in New York from the sounds of the weak-fish—*Otolithus regalis* of Cuvier (Storer, *Rep. on Fishes of Mass.*, p. 33)—and perhaps of other fishes caught in the neighborhood. The sounds are dried whole, or merely split open, and vary much in size and texture, weighing from a drachm to an ounce. An article called *refined* or *transparent isinglass* is made by dissolving the New England isinglass in hot water, and spreading the solution to dry on oiled muslin. It is in very thin, transparent plates, and is an excellent glue, but retains a strong fishy odor. A variety of Ichthyocolla, called *India* or *China isinglass*, has been consumed largely in China from time immemorial, and became known to the Europeans of India about 1839. It is now found in the markets of London, where it is chiefly employed in clarifying beer. (*Journ. de Pharm.*, Fév. 1870, p. 153.) It is the swimming-bladder derived from two species of *Polynemus*, and from several other species of fish in the Indian waters. (*Ibid.*, Janv. 1873, p. 77.) Preparations such as *Nelson's* and *Coxe's gelatin* are largely used now as substitutes for isinglass in making jellies. They are made from selected bones, and the gelatin is concentrated in vacuo and filtered clear, and often bleached with sulphurous acid. (See *Gelatinum*, p. 647.)

Mr. C. T. Carney states that the New England isinglass is prepared from the sounds of the hake (*Gadus merluccius*), by the following process. Having been taken from the fish, split open, cleansed, and dried, they are soaked in water till sufficiently soft, then passed through rollers so as to form a large, homogeneous, dough-like sheet, which is cut into strips, and then again passed through rollers till reduced to a ribbon-like form. The pieces thus prepared are thoroughly dried, and folded into bundles. (*Proc. A. P. A.*, 1857; see also *A. J. P.*, 1894, 447.)

According to Dr. V. Griessmayer, the skin of the ray (*Raja*, a tribe of deep-sea fishes, with flat body and naked and often leather-like skin) has been much used, particularly in France, in place of isinglass, as a clarifying agent in brewing. The skin of the thornback or rough ray (*Raja clavata*) is, according to Jericka, the best for this purpose. The clarifying mixture prepared from this is without color, odor, or taste, and clears any turbid liquid in a short time, or at least within three days, if the liquid is kept in a very cold place. This clarifier is said to be superior to either Russian or American isinglass. (*N. R.*, Feb. 1879.) Isinglass is sometimes kept in the shops cut into fine shreds, and is thus more easily acted on by boiling water.

Properties. In its purest form it is "in separate sheets, sometimes rolled, of a horny or pearly appearance; whitish or yellowish, semi-transparent, iridescent, inodorous, insipid; almost entirely soluble in boiling water and in boiling diluted alcohol. A solution of isinglass in 24 parts of boiling water forms, on cooling, a transparent jelly." *U. S.* The inferior kinds are yellowish and more opaque. In cold water it softens, swells up, and becomes opalescent. Boiling water entirely dissolves it, with the exception of a minute proportion of impurities, amounting, according to Mr. Hatchet, to less than 2 per cent. The solution on cooling assumes the form of a jelly, which consists of pure gelatin and water. Isinglass is in fact the purest form of *gelatin* with which we are acquainted, and may be used whenever this principle is required as a test. It is insoluble in alcohol, but is dissolved readily by most of the diluted acids, and by alkaline solutions. It has a strong affinity for tannin, with which it forms an insoluble compound. Boiled with sulphuric acid, it is converted into a peculiar substance, called *glycocoll* or *sugar of gelatin*, which is in reality *amido-acetic acid*, $C_2H_3(NH_2)O_2$. Its aqueous solution speedily putrefies. (See *Gelatinum*, p. 647.) An ingenious adulteration has been practised by rolling a layer of gelatin between two layers of genuine isinglass. This may be detected by the disagreeable odor and taste of the adulterated drug, and the effects of water upon it. Genuine isinglass, cut into shreds and treated with water, becomes opalescent and more opaque than before; while the shreds, though they soften and swell, remain unbroken, and when examined by the microscope are seen to be decidedly fibrous. Gelatin, on the contrary, when similarly treated, becomes more transparent than before; the shreds are disintegrated, and the structure appears amorphous under the microscope. In the adulterated article both these characters are presented in layers more or less distinct. (*P. J. Tr.*, ix. 505.) Moreover, Redwood and Letheby observed that the ash of true isinglass does not exceed 0·9 per cent., while glue contains from 2 to 4 per cent. of ash. An adulterated isinglass would therefore yield more ash than the normal. A *false isinglass* has been imported into England from Para, in Brazil, consisting of the dried ovary of a large fish. It has somewhat the form of a bunch of grapes, consisting of ovoid or roundish masses attached by a footstalk to a central axis. It is not

gelatinous, and is unfit for the purposes to which isinglass is applied. (*A. J. P.*, xxv. 144.)* For table showing value of different kinds of European isinglass, see *P. J. Tr.*, 1884, p. 900.

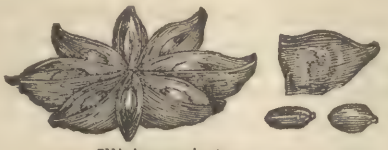
Medical Properties and Uses. Isinglass has no peculiar medical properties. It may be given internally, in the form of jelly, as a slightly nutritious article of diet; but it has no advantage over the jelly made from calves' feet. Three drachms impart sufficient consistency to a pint of water. It is employed for clarifying liquors, and imparting lustre to various woven fabrics. Added in small quantities to vegetable jellies, it gives them a tremulous appearance, which they lack when unmixed. As a test of tannin it is strongly recommended by Prof. Wm. T. Wenzell, who uses it instead of hide powder in the estimation of tannin. (*A. J. P.*, 1894, 447.) It forms the coating of *court-plaster.*

ILLICIUM. U. S. Illicium. [Star-Anise.]

(IL-LĬ'CI-ŬM.)

"The fruit of Illicium verum, Hooker filius (nat. ord. Magnoliaceæ)." *U. S.*

Chinese Anise, Fructus Anisi Stellati; Semen Badiani, Badiane, Anise étoilé, *Fr.*; Sternanis, *G.*



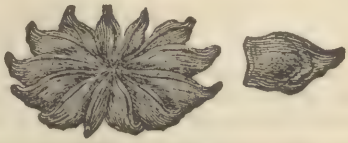
Of the genus Illicium, seven species are recognized, of which two are found on the Atlantic coast of Southern North America, two in Hindostan, and three in China and Japan. Many of the species are possessed of aromatic properties. *I. floridanum*, a small evergreen tree or shrub with oblong-lanceolate, acuminate leaves, which grows westward from Florida along the coast bounding the Gulf of Mexico, has its bark, leaves, and probably also seed-vessels endowed with a spicy odor and taste, analogous to those of anise. Another species, *I. parviflorum*, a shrub found by Michaux in the hilly regions of Georgia and Carolina, has a flavor closely resembling that of sassafras root. A decoction of the seeds is said to produce violent gastro-intestinal irritation, followed by motor and sensory paralysis, with convulsions and death if the dose have been sufficient. E. Barral (*Revue Gén. de. Clin.*, Oct. 1889) states that he has obtained a poisonous glucoside from the kernel. The *Illicium anisatum* is a small tree, twenty-five or thirty feet high, bearing small yellow and white flowers. As was pointed out by Mr. Piry in 1878, and confirmed by Dr. Bretschneider, star-anise is chiefly produced in the extreme southeast portion of China, in the provinces of Kwang-si and Kwang-tung, especially in the mountainous region between the Tso-kiang and the Yu-kiang, and also in Annam, and finds exit principally through the port of Pakhoi. Although Bentley and Trimen give *I. anisatum* as the botanical source of star-anise, yet the assertion of Bretschneider that the botanical source of the plant is unknown, led to seeds being sent from the Hong-Kong Botanical Gardens to Kew, and a successful cultivation resulted in the description by Sir Joseph Hooker of a new species of *Illicium*, under the name of *I. verum*. (*Bot. Mag.*, t. 7005, July, 1888.) The leading features in the plant appear to be the solitary axillary globular flowers, which do not expand fully, the segments remaining convex, the inner segments being red, and the ten stamens, in which the filament forms with the connective an avoid body. The peduncles are curved and barely half an inch in length.

Illicium anisatum was examined by C. E. Schlegel (*A. J. P.*, 1885, p. 426), who found *saponin* in the aqueous extract; in the alcoholic extract a crystalline principle of a strong musk-like odor, which did not show alkaloidal or glucosidal reactions; and oil of star-anise. *I. floridanum* was examined by Henry C. C. Maisch (*A. J. P.*, 1885, p. 278), who obtained from the leaves, besides essential oil, crystals of a glucoside to which probably the bitter taste of the leaves is due. The root-bark and the capsules both yielded a neutral crystalline principle insoluble in alcohol and ether, but soluble in chloroform, melting at 110° C. (230° F.).

The *I. religiosum*, or *shikimi*, of India, is very poisonous, causing vomiting and epileptiform

* *Japanese Isinglass.* Two forms of this substance are described by Mr. Hanbury, one in irregularly four-sided sticks, about eleven inches long, very light and porous, the other in long shrivelled strips about one-eighth of an inch thick. It is translucent, yellowish white, without smell or taste, insoluble in cold water, but swelling up and softening under its influence, and dissolved in great measure by boiling water, with which it gelatinizes on cooling. The peculiarities of this substance are owing to a principle denominated *gelose* by Payen, which resembles gelatin in its gelatinizing property, but differs in its chemical relations, and is probably peculiar. It resembles the carrageenin of Irish moss, but has a greater gelatinizing power. The jelly formed by dissolving it in boiling water and allowing the solution to cool requires a higher temperature to liquefy it than gelatin jelly, and does not melt in the mouth. Gelose differs from gelatin in not being precipitated by tannic acid, and from rice jelly in not being rendered blue by iodine. Japan isinglass is used for the same purposes as that of animal origin. It is derived, according to Mr. Hanbury, from different species of various genera of sea-weed, and especially *Gelidium corneum*. (See *A. J. P.*, 1860, p. 354.) The term *Agar Agar*, in the East Indies, is applied to several sea-weeds prepared for food. (See PART II.; also *Proc. A. P. A.*, xxvi. 173; *P. J. Tr.*, xi. 137.)

convulsions, with dilated pupil and exceedingly cyanosed countenance :* in it has been found by Mr. J. F. Eykman (*P. J. Tr.*, xi. 1046) a crystalline principle, for which the name of *shikimine* or *sikimine*† has been proposed. The accompanying cuts portray the differences in the capsules of several species.



Illicium anisatum.

Illicium religiosum.

Illicium griffithii.

Illicium magus.

Properties. "The fruit is pedunculate and consists of eight stellately arranged carpels, which are boat-shaped, about 10 Mm. long, rather woody, wrinkled, straight-beaked, brown, dehiscent on the upper suture, internally reddish-brown, glossy, and containing a single, flattish, oval, glossy, brownish-yellow seed; odor anise-like; taste of the carpels sweet and aromatic, and of the seeds oily. Star-anise should not be confounded with the very similar but poisonous fruit of *Illicium anisatum* Linné (*Illicium religiosum* Siebold), the carpels of which are more woody, shrivelled, and have a thin, mostly curved beak, a faint, clove-like odor, and an unpleasant

* The following table gives the distinctive characters which, according to Mr. J. F. Eykman, distinguish the oil of *Illicium religiosum* from allied oils (*P. J. Tr.*, xi. 1048):

	Ol. Anisi Vulgaris.	Oleum Fœniculi.	Ol. Illicii Anisati.	Ol. Illicii Religiosi.
Constituents . . .	Chiefly solid and liquid anethol.	Small quantity of terpene boiling at 190° C., and liquid and solid anethol.	Chiefly solid and liquid anethol.	Rather much of a terpene boiling at 173° to 176° C.; liquid anethol boiling at 232° to 233° C.
Melting Point . .	+6° to +18° C.	—2° to +18° C.	About 0° C.	Not solid when cooled to 20° C.
Specific Gravity .	About 0·903.	0·94 to 0·998.	0·978.	1·006.
Molecular Rotation.	0° to +0·5°.	+13° to +19·6°.	0° to —0·4.°,	—8·6°.
Alcoholic Hydrochloric Acid.	Colorless, afterwards reddish, then pale red.	Colorless.	Colorless.	Colorless, afterwards blue.
Chloral Reagent .	Colorless, afterwards yellow and brownish.	Colorless, then beautiful red.	Colorless, then beautiful red.	Colorless, afterwards dirty brown-yellow.
Ammoniacal Silver Solution.	In 24 hours no reduction.	Like ol. anisi vulgaris.	Like ol. anisi vulgaris.	Reduction in a few hours.
Hager's Reaction	In alcohol, a portion of the sulphuric acid and oil mixture remains undissolved as a thick mass adhering to the sides of the tube.	Mixture of oil, sulphuric acid, and alcohol is perfectly clear.	Like ol. anisi vulgaris.	Mixture is nearly clear; separation of a little reddish-white deposit.
10 drops of oil, with 60 drops of ether and about 0·15 gramme of sodium.	Colorless; after 4 hours the mixture nearly colorless; deposit yellowish white.	. . . . .	Colorless; after 4 hours liquid and deposit yellow.	Colorless; quickly bluish; after 4 hours liquid pale yellow, deposit yellow.

† Sikimine is violently poisonous, belonging to the group of convulsants of which picrotoxin is the type. Plugge and Schutte associate in this group—*Dioscorine*, the alkaloid of Dioscorea hirsuta; *Cicutoxine*, the alkaloid of Cicuta virosa; *Coriamyrtin*, a glucoside of Coriaria myrtifolia; *Digitalirésine* and *Toxirésine*, prepared by Schmiedeberg from digitalin and digitoxin; *Phytolaccatoxine*, the alkaloid of Phytolacca acinosa; *Sikimine; Œnanthotoxine*, the alkaloid obtained from the Œnanthe crocata, by Pohl; *Isonitroso-anilacétone*, an artificial substance prepared by Holleman. (See *Archiv. Internat. d. Pharmacodyn.*, iv., 1897.)

taste." *U. S.* Star-anise is used principally as a source of oil of anise, which is prepared by distillation not only in Southwestern China, but also in enormous quantities in Annam, where it is enclosed in tinned vessels and sent into commerce through China.

Eykman (*Pharm. Journ.*, 1885, p. 985) has shown that in the essential oil of the fruit of *Illicium religiosum safrol*, $C_{10}H_{10}O_2$, is found, accompanied by *eugenol*, $C_{10}H_{12}O_2$. On the other hand, the chief constituent of the oil of *Illicium anisatum* is anethol, $C_{10}H_{12}O$. The constituents of low boiling point in star-anise oil, consisting of terpenes essentially, have been reported upon by the chemists of Schimmel & Co. (*Semi-annual Report*. April, 1893). They find *dextro-pinene*, boiling at 157° to 163° C. (314·6° to 325·4° F.), and *lævo-phellandrene*, boiling at from 170° to 175° C. (338° to 347° F.). The medical properties of the oil of star-anise are probably similar to those of oil of anise, for which its oil has been largely substituted.

INFUSA. U. S. Infusions.

(IN-FU'ṢA.)

Tisanes, Infusions, *Fr.;* **Infusionen, Aufgüsse,** *G.*

These are aqueous solutions obtained by treating with water, without the aid of ebullition, vegetable products only partially soluble in that liquid. The water employed may be hot or cold, according to the objects to be accomplished. Infusions are generally prepared by pouring boiling water upon the vegetable substance and macerating in a tightly closed vessel till the liquid cools. The soluble principles are thus extracted more rapidly, and, as a rule, in a larger proportion, than at a lower temperature. Some substances, moreover, are dissolved in this manner which are nearly or quite insoluble in cold water. A prolonged application of heat is in some instances desirable; and this may be effected by placing the vessel near the fire. Cold water is preferred when the active principle is highly volatile, when it is injured by heat, or when any substance of difficult solubility at a low temperature exists in the vegetable, which it is desirable to avoid in the infusion. A longer continuance of the maceration is necessary in this case; and in warm weather there is sometimes danger that spontaneous decomposition may commence before the process is completed. When a strong infusion is required, the *process of percolation* may be advantageously resorted to. The water employed should be free from saline impurities, which frequently produce precipitates and render the infusion turbid. Fresh river, rain, or distilled water is usually preferable to that of pumps or springs, except when the latter are known to produce water which will not react with any of the constituents of the infusion.

The substance to be acted on should be sliced or bruised, or in the state of powder; but, unless when percolation is employed, this last condition is seldom requisite, and is always inconvenient, as it requires that the infusion should be filtered through paper in order completely to separate the undissolved portion. In other cases it is sufficient to strain it through fine linen or muslin. When percolation is resorted to, the substance should be more or less finely powdered. The United States Pharmacopœia furnishes a general formula for infusions, which is to be used when the proportions are not specified. In the U. S. P. 1880 the strength of such infusions was fixed at 10 per cent. Experience has shown, however, that this was too strong for general purposes, and in the U. S. P. 1890, 5 per cent. has been chosen as the limit.

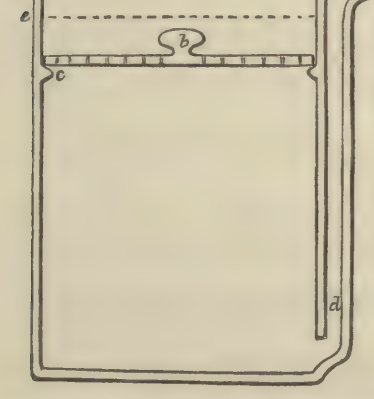
General Formula for Infusions, U. S. P.

"An ordinary Infusion, the strength of which is not directed by the physician, nor specified by the Pharmacopœia, shall be prepared by the following formula:

"Take of

The Substance, coarsely comminuted, *fifty grammes* [or 1 ounce av., 334 grains];
Boiling Water, *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms];
Water, *a sufficient quantity*,

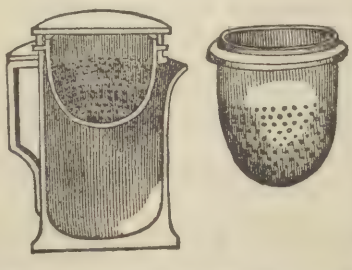
To make *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].



"Put the substance into a suitable vessel provided with a cover, pour upon it the Boiling Water, cover the vessel tightly, and let it stand for half an hour. Then strain, and pass enough Water through the strainer to make the Infusion measure *one thousand cubic centimeters* [or 33 fluidounces, 6½ fluidrachms].

"*Caution.*—The strength of Infusions of energetic or powerful substances should be specially prescribed by the physician." *U. S.*

Infusions are usually prepared in glazed earthenware or porcelain vessels fitted with covers. Mr. Brande suggests the use of clean metallic vessels, which, when finely polished, retain the heat for a longer time; but they are also more liable to chemical alteration, and may sometimes injuriously affect the preparation. Vessels of block-tin are generally well adapted for the purpose.*



As infusions do not keep well, especially in warm weather, they should be made extemporaneously and in small quantities. In this country they are usually prepared in families, and the propriety of their introduction into the Pharmacopœia has been doubted; but it is desirable to have certain fixed standards for the regulation of the medical practitioner, and it is sometimes convenient to direct infusions from the apothecary, for whose guidance official formulas are necessary. Physicians would, indeed, find an advantage in more frequently directing them to be prepared by the pharmacist, instead of leaving their preparation to the carelessness or want of skill of attendants upon the sick. Infusions may be kept during hot weather, and for many months, by straining them *while hot*, and pouring them at once into bottles provided with accurately ground stoppers. The bottle must be full, the stopper being made to displace its bulk of the fluid. A common bottle with a cork stopper may be used, if the softened cork be forced into the full bottle, tied down, and at once dipped into hot sealing-wax. The hotter the liquid and the freer from air the better will the infusion keep. Sterilization of infusions by heating them to the boiling point, then preserving in bottles which have been kept hot to destroy germs, and stoppered with sterilized cotton, is effective, particularly if the bottles have a stop-cock near the bottom to draw the infusion when wanted. Prof. Alméns has proposed a very efficient method of preserving infusions. (*A. J. P.*, April, 1875.) It is as follows. The infusion or decoction is heated for some time in a water-bath at 100° C. (212° F.), and the bottle is then fitted with a tight cork, through which a glass tube passes, lightly filled with cotton wool. The cork has a second opening, through which a glass tube passes nearly to the bottom of the bottle; this tube is bent at a sharp angle and has fitted to it a piece of india-rubber tubing, to which a pinch-cock is attached, by means of which the contents may be drawn as wanted. By making very concentrated infusions, as suggested by Mr. Donovan, with a mixture of three parts of water and one part of alcohol, they may be long

* *Alsop's Infusion Jar.* This presents a very neat and effectual method of making the hot infusions. It consists of an earthenware mug, represented in the marginal figure, with a spout (*d*) proceeding from the bottom, and placed closely to the side of the vessel to prevent fracture; a perforated plate or diaphragm (*b*), supported on a ledge (*c*), at about one-quarter or one-third of the height of the vessel from the top; and a lid (*a*), which may be fastened on by a string through holes (*f f*). The material to be submitted to infusion is placed on the perforated plate, and the hot water poured in so as to cover it, the vessel having been previously warmed so as not to chill the liquid. As the water becomes impregnated, it acquires an increased specific gravity, and sinks to the bottom, its place being supplied by the unsaturated portion; and this circulation goes on until the whole of the soluble matter is extracted. In order to maintain a due warmth, the vessel may be placed upon a stove or an iron plate near the fire.

The advantage of the process is that the material is subjected to the solvent power of the least impregnated portion of the menstruum. Such jars may now be had in Philadelphia. In order that the vessel may be adapted for the preparation of different quantities of infusions, it would be an advantage to have ledges arranged within, at different heights, so that the diaphragm may be supported at any desirable point. The surface of the liquid (*e*) should of course always be above the medicinal substance placed upon the diaphragm. (See *A. J. P.*, viii. 89.)

Squire's Infusion Mug. Mr. Squire, of London, has modified this jar by adding a colander of queensware, which is closely covered with a lid, and descends into the jar so as to form a diaphragm for the support of the substance to be infused. It has the advantage that the material, after having been exhausted, may be lifted out without disturbing the infusion. In the margin is a figure of the mug. It is made of queensware, of the capacity of two pints, into which a thimble-shaped colander descends to somewhat less than half its depth, supported on the rim of the mug by a projecting ledge, with a carefully fitted cover, which closes the whole. The substance to be submitted to infusion is introduced into the colander either before or after it has been fitted to the mug; the water, hot or cold, as the case may be, is then poured in so as to fill the lower vessel, and cover the materials in the upper; and, the cover having been applied, the vessel is set aside for the length of time required. The colander is then to be lifted out, and the infusion is ready for use.

kept, and when used can be diluted with water to the proper strength. Thus, if made four times as strong as the official infusion, they may be diluted with three measures of water. The proportion of alcohol would thus be very small; but it might still be medically injurious; and infusions should not be prepared in this way unless with the cognizance of the prescriber.

Mr. Battley, of London, has introduced a set of preparations, which he calls *inspissated infusions*, the advantages of which are that the virtues are extracted by cold water, are not injured by heat used in the evaporation, are in a concentrated state, and are not impaired by time. To prepare them he macerates the material, coarsely powdered, bruised, or finely sliced, in twice its weight of cold distilled water, pressing the solid matter into the liquid repeatedly by a rammer or the hand; then allows the liquid to drain out, or expresses it in the case of highly absorbent substances; and repeats the process, with an amount of water equal to that which has been separated, until the strength is exhausted. Four or six hours of maceration are usually sufficient. The infusion is then to be concentrated by evaporation, at a temperature not exceeding 71·1° C. (160° F.) to the sp. gr. 1·200, and as much alcohol is to be added as will make its sp. gr. 1·100. These preparations are very analogous to the *fluid extracts* already treated of. As a rule, it would probably be preferable to prepare the infusion by the process of percolation. The inspissated infusions must be diluted when administered. The presence of alcohol, though in small quantity, would sometimes be a serious objection. (*P. J. Tr.*, x. 129.) *Concentrated infusions* of the strength of 50 per cent. were introduced into the British Pharmacopœia (1898); they are mostly made by percolation, and are termed "Liquors." (See *Liquor Chiratæ Concentratus.*) This certainly leads to confusion in nomenclature, and it is difficult to understand why they were not called concentrated infusions, particularly as their almost universal use is for making ordinary infusions by diluting with water.

As we have already treated of the chemical relations and medical properties of the substances used in infusion, it would be useless repetition to enlarge upon these points in the following details. We shall touch upon them only in cases of peculiar interest, or where changes requiring particular notice may grow out of the nature of the process.*

* At the several revisions of the Pharmacopœias the following Infusions have been dropped from the official lists. We give the former official formulæ.

Infusum Eupatorii. U. S. 1870. *Infusion of Thoroughwort.* "Take of Thoroughwort or Boneset [the dried herb] *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." As a tonic, this infusion should be taken cold in the dose of one or two fluidounces (30 or 60 C.c.) three or four times a day, or more frequently; as an emetic and a diaphoretic, in large tepid draughts. It is popularly called *boneset tea.*

Infusum Juniperi. U. S. 1870. *Infusion of Juniper.* "Take of Juniper, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for an hour in a covered vessel, and strain." The whole quantity may be taken in twenty-four hours, in doses of from two to three fluidounces (60–90 C.c.).

Infusum Pareiræ. U. S. 1870. *Infusion of Pareira Brava.* "Take of Pareira Brava, bruised, *a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." The infusion of pareira brava is highly esteemed by some English practitioners as a remedy in irritation and chronic inflammation of the urinary passages, and has been found useful in catarrh of the bladder. The dose is from one to two fluidounces (30–60 C.c.). Brodie employed a *decoction* of the root, which he prepared by boiling half an ounce in three pints of water down to a pint, and gave in the quantity of from eight to twelve fluidounces daily. The British Pharmacopœia has substituted the decoction for the infusion.

Infusum Picis Liquidæ. U. S. 1870. *Infusion of Tar. Tar Water.* "Take of Tar *a pint;* Water *four pints.* Mix them, and shake the mixture frequently during twenty-four hours. Then pour off the infusion, and filter through paper." Water takes from tar a small portion of acetic acid, empyreumatic oil including creosote, and resinous matter, acquiring a sharp empyreumatic taste, the odor of tar, and the color of Madeira wine. Thus impregnated, it is stimulant and diuretic, and may be taken in the quantity of from one to two pints daily. It is also used as a wash in chronic cutaneous affections, and is said to have proved beneficial, by injection into the bladder, in some cases of chronic cystitis.

Infusum Salviæ. U. S. 1870. *Infusion of Sage.* "Take of Sage *half a troyounce;* Boiling Water *a pint.* Macerate for half an hour in a covered vessel, and strain." This preparation is less used internally than as a gargle, or as a vehicle for other substances, such as alum, employed in this way.

Infusum Spigeliæ. U. S. 1870. *Infusion of Spigelia.* "Take of Spigelia *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." The dose of this infusion, for a child two or three years old, is from four fluidrachms to a fluidounce (15–30 C.c.); for an adult, from four to eight fluidounces (118–236 C.c.), repeated morning and evening. A quantity of senna equal to that of the spigelia is usually added, to insure a cathartic effect.

Infusum Taraxaci. U. S. 1870. *Infusion of Dandelion.* "Take of Dandelion, bruised, *two troyounces;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." The dose is a wineglassful two or three times a day, or oftener.

Infusum Zingiberis. U. S. 1870. *Infusion of Ginger.* "Take of Ginger, bruised, *half a troyounce;* Boiling Water *a pint.* Macerate for two hours in a covered vessel, and strain." The dose of this infusion is two fluidounces (60 C.c.).

Infusum Catechu. Br. 1885. *Infusion of Catechu.* "Take of Catechu, in coarse powder, *one hundred and sixty grains;* Cinnamon Bark, bruised, *thirty grains;* Boiling Distilled Water, *ten fluidounces* [Imp. meas.]. Infuse in a covered vessel, for half an hour, and strain." *Br.* An agreeable mode of administering catechu. Dose, from one to three fluidounces (30–90 C.c.).

INFUSUM AURANTII. Br. Infusion of Orange Peel.

(ĮN-FŪ'ZŬM ÂU-RĂN'TĮ-Ī—âw-răn'shę-ī.)

Tisane d'Ecorce d'Orange, *Fr.;* Pomeranzenschalen-Aufguss, *G.*

"Dried Bitter-Orange Peel, cut small, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

A grateful stomachic. Dose, from one-half to one fluidounce (15–30 C.c.).

INFUSUM AURANTII COMPOSITUM. Br. Compound Infusion of Orange Peel.

(ĮN-FŪ'ZŬM ÂU-RĂN'TĮ-Ī CǪM-PŎZ'Į-TŬM.)

Tisane d'Ecorce d'Orange composée, *Fr.;* Pomeranzen- und Citronenschalen-Aufguss, *G.*

"Dried Bitter-Orange Peel, cut small, ½ *ounce* (Imperial) or 25 grammes; Fresh Lemon Peel, cut small; ¼ *ounce* (Imp.) or 12·5 grammes; Cloves, bruised, 55 *grains* (Imp.) or 6·25 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

A grateful stomachic in the dose of from one-half to one fluidounce (15–30 C.c.).

INFUSUM BUCHU. Br. Infusion of Buchu.

(ĮN-FŪ'ZŬM BŪ'ȻHŪ—bū'kū.)

Infusum Diosmæ, s. Barosmæ; Tisane de Bucco, *Fr.;* Buchuaufguss, *G.*

"Buchu Leaves, freshly broken, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

It has the odor, taste, and medical virtues of the leaves, and affords a convenient method of administering the medicine. Dose, from one to two fluidounces (30–60 C.c.).

INFUSUM CALUMBÆ. Br. Infusion of Calumba.

(ĮN-FŪ'ZŬM CĄ-LŬM'BÆ.)

Tisane de Colombo, *Fr.;* Kolombo-Infusion, *G.*

"Calumba Root, thinly sliced, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, cold, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse for half an hour; strain." *Br.*

The infusion of columbo is apt to spoil very quickly, especially in warm weather. It has been generally supposed that the cold infusion would keep better than the hot, because it contains no starch. Mr. Thomas Greenish, however, upon comparing specimens of the two infusions, found that the spontaneous change began sooner in the cold than in the hot, though the former was clearer. Columbo contains starch and albumen. Cold water extracts the latter without the former; hot water the former with comparatively little of the latter, which is partially coagulated by the heat. Both starch and albumen are liable to spontaneous change; but the former is much the more permanent of the two. Hence it is, according to Mr. Greenish,

Infusum Cusso. Br. 1885. *Infusion of Kousso.* "Take of Kousso, in coarse powder, *one-half an ounce* [avoirdupois]; Boiling Distilled Water *eight fluidounces* [Imp. meas.]. Infuse in a covered vessel, for fifteen minutes. Not to be strained." *Br.* The whole may be taken for a dose. The *infusion of brayera* (kousso) was very properly dropped at the 1890 revision of the U. S. P. The old formula is as follows: "Brayera, in No. 20 powder, *six parts* [or one ounce avoirdupois]; Boiling Water, *one hundred parts* [or one pint]. Pour the Boiling Water upon the Brayera, and let it macerate in a covered vessel until cool. This infusion should be dispensed without straining it." *U. S.* 1880.

Infusum Jaborandi. Br. 1885. *Infusion of Jaborandi.* "Take of Jaborandi, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces* [Imp. meas.]. Infuse in a covered vessel, for half an hour, and strain." *Br.* This preparation is efficient, but from its nauseousness and tendency to sicken the stomach is inferior to the alkaloid or even the fluid extract. Dose, from one to two fluidounces (30–60 C.c.).

Infusum Lini. Br. 1885. *Infusion of Linseed.* "Take of Linseed *one hundred and fifty grains;* Dried Liquorice Root, in No. 20 powder, *fifty grains;* Boiling Distilled Water *ten fluidounces.* Infuse in a covered vessel, for two hours, and strain." *Br.* This is nearly identical with the *Compound Infusion of Flaxseed* of the U. S. P. 1870. It is a useful demulcent drink in inflammatory affections of the mucous membrane of the lungs and urinary passages. It may be taken *ad libitum.*

Infusum Maticæ. Br. 1885. *Infusion of Matico.* "Take of Matico Leaves, cut small, *half an ounce* [avoirdupois]; Boiling Distilled Water, *ten fluidounces* [Imp. meas.]. Infuse in a covered vessel, for half an hour, and strain." *Br.* The dose of this infusion is two fluidounces (60 C.c.).

Infusum Valerianæ. Br. 1885. *Infusion of Valerian.* "Take of Valerian Rhizome, bruised, *a quarter of an ounce* [avoirdupois]; Boiling Distilled Water *ten fluidounces* [Imp. meas.]. Infuse in a covered vessel, for one hour, and strain." *Br.* The dose of this infusion is two fluidounces (60 C.c.), repeated three or four times a day, or more frequently.

that the hot infusion keeps best. Indeed, he ascribes the change which takes place in the starch of the hot infusion chiefly to the agency of a little albumen which has escaped coagulation. According to these views, the best plan of preparing infusion of columbo is to exhaust the root with cold water, by which the starch is left behind, and then to heat the infusion to the boiling point in order to coagulate the albumen. (*A. J. P.*, xviii. 141; from *P. J. Tr.*) Upon comparing specimens of the cold and the hot infusion, we have not found the results of Mr. Greenish fully confirmed. The cold infusion appeared to keep better than the hot. Nevertheless the plan of preparing the infusion above proposed is probably the best. The infusion of columbo is not disturbed by salts of iron, and may be conveniently administered in connection with them. The dose is one fluidounce (30 C.c.) three or four times a day.

INFUSUM CARYOPHYLLI. Br. Infusion of Cloves.

(ĮN-FŪ'ŞŬM CĂR-Y-O-PHĬL'LĪ.)

Tisane de Girofle, *Fr.;* **Gewürznelken-Infusion,** *G.*

"Cloves, bruised, ½ *ounce* (Imperial) or 25 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The infusion of cloves affords precipitates with lime water, and with the soluble salts of iron, zinc, lead, silver, and antimony. (Phillips.) Dose, one fluidounce (30 C.c.).

INFUSUM CASCARILLÆ. Br. Infusion of Cascarilla.

(ĮN-FŪ'ŞŬM CĂS-CĄ-RĬL'LÆ.)

Tisane de Cascarille, *Fr.;* **Kaskarilla-Aufguss,** *G.*

"Cascarilla, in No. 10 powder, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

This infusion affords precipitates with lime water, infusion of galls, silver nitrate, lead acetate and subacetate, zinc sulphate, and ferrous sulphate. Dose, one fluidounce (30 C.c.).

INFUSUM CHIRATÆ. Br. Infusion of Chiretta.

(ĮN-FŪ'ŞŬM ØHĮ-RĀ'TÆ—kį-rā'tē.)

Tisane de Chirette, *Fr.;* **Chiretta-Thee,** *G.*

"Chiretta, cut small, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

The dose of this simple bitter infusion is from one-half to one fluidounce (15–30 C.c.).

INFUSUM CINCHONÆ. U. S. (Br.) Infusion of Cinchona.

(ĮN-FŪ'ŞŬM CĬN-ØHŌ'NÆ—sĭn-kō'nē.)

Infusum Cinchonæ Acidum, *Br.;* **Acid Infusion of Cinchona; Infusion of Yellow Bark; Infusion of Calisaya Bark; Tisane de Quinquina jaune,** *Fr.;* **Kalisaya-Rindenaufguss,** *G.*

"Cinchona, in No. 40 powder, *sixty grammes* [or 2 ounces av., 51 grains]; Aromatic Sulphuric Acid, *ten cubic centimeters* [or 162 minims]; Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]. Mix the Acid with *five hundred cubic centimeters* [or 16 fluidounces, 435 minims] of Water, and moisten the powder with *thirty cubic centimeters* [or 1 fluidounce, 7 minims] of the mixture; pack it firmly in a conical glass percolator, and gradually pour upon it, first, the remainder of the mixture, and afterwards Water, until the Infusion measures *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]." *U. S.*

"Red Cinchona Bark, in No. 40 powder, 1 *ounce* (Imperial) or 50 grammes; Aromatic Sulphuric Acid, 2 *fl. drachms* (Imp. meas.) or 12·5 cubic centimetres; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Mix the Red Cinchona Bark with the Distilled Water in a covered vessel; add the Aromatic Sulphuric Acid; infuse for one hour; strain." *Br.*

Though the infusion with boiling water is more quickly prepared than the cold infusion, and therefore better adapted to cases of emergency, yet the former is a more elegant preparation, not turbid like the latter, and at least equally efficient. We therefore prefer the process of the U. S. Pharmacopœia, provided it be skilfully conducted.

The U. S. infusion is an efficient preparation. Water extracts from bark quinine and cinchonine kinates, but leaves behind the compounds which these principles form with the cinchotannic acid. The simple infusion, therefore, is rather feeble. But the addition of the acid

insures the solution of all or nearly all the active matter. Dr. Geo. B. Wood placed much reliance on this infusion. It would be best to macerate the bark with the acidulated water some time before it is introduced into the percolator. The infusion of cinchona, made without acid, affords precipitates with the alkalies, alkaline carbonates, and alkaline earths; the soluble salts of iron, zinc, and silver; corrosive mercuric chloride, arsenous acid, and tartar emetic; gelatinous solutions; and various vegetable infusions and decoctions, as those of galls, chamomile, columbo, cascarilla, horseradish, cloves, catechu, orange-peel, foxglove, senna, rhubarb, valerian, and simaruba. In some instances the precipitate occurs immediately, in others not for several hours. Few, however, of these substances diminish the efficacy of the infusion, as they do not affect the active principles. The alkalies, alkaline earths, and vegetable astringents are really incompatible. As gallic, tartaric, and oxalic acids form salts with quinine of somewhat difficult solubility, the neutral and soluble gallates, tartrates, and oxalates produce in the infusion slight precipitates of corresponding salts of the alkaloids; but these are redissolved by an excess of the acid. Antimony and potassium tartrate does not precipitate the alkaloids. Solutions of iodine are incompatible, forming with the alkaloids insoluble compounds. For an account of the chemical reactions of the infusions of different varieties of cinchona bark, see *A. J. P.* ix. 128. The simple infusion of cinchona may be advantageously administered in cases which require tonic treatment but do not call for the full powers of the bark. The acid infusion has all the powers of cinchona itself. The medium dose is one fluidounce (30 C.c.), equivalent to a drachm of the bark.

INFUSUM CUSPARIÆ. Br. Infusion of Cusparia.

(ĮN-FŪ'ZŬM CŪS-PĀ'RĮ-Æ.)

Tisane d'Angusture, *Fr.;* Angustura-Aufguss, *G.*

"Cusparia Bark, in No. 20 powder, 1 *ounce* (Imperial) or 50 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*

Under the name of *Infusum Angusturæ* this preparation was official in the U. S. Pharm. 1870, made in the proportion of half a troyounce of Angustura bark in a pint of water. The dose of the infusion is two fluidounces (60 C.c.), repeated every two, three, or four hours.

INFUSUM DIGITALIS. U. S., Br. Infusion of Digitalis.

(ĮN-FŪ'ZŬM DĮĢ-Į-TĀ'LĮS.)

Tisane de Digitale, *Fr.;* Fingerhutaufguss, *G.;* Infusion of Foxglove.

"Digitalis, bruised, *fifteen grammes* [or 231 grains]; Alcohol, *one hundred cubic centimeters* [or 3 fluidounces, 183 minims]; Cinnamon Water, *one hundred and fifty cubic centimeters* [or 5 fluidounces, 35 minims]; Boiling Water, *five hundred cubic centimeters* [or 16 fluidounces, 435 minims]; Cold Water, *a sufficient quantity*, To make *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]. Upon the Digitalis, contained in a suitable vessel, pour the Boiling Water, and allow it to macerate until the mixture is cold. Then strain, add the Alcohol and Cinnamon Water to the strained liquid, and pass enough Cold Water through the residue on the strainer to make the product measure *one thousand cubic centimeters* [or 33 fluidounces, 391 minims]." *U. S.*

"Digitalis Leaves, in No. 20 powder, 60 *grains* (Imperial) or 6·8 grammes; Distilled Water, boiling, 1 *pint* (Imp. meas.) or 1000 cubic centimetres. Infuse in a covered vessel for fifteen minutes; strain." *Br.*
